The results are presented in Figures 2 through 8. At this point, it will be stressed that the results presented are more qualitative than they are quantitative.

Figure 2 shows freezing when there is no density inversion. It shows one circulation cell inside the liquid phase, with fluid flow up at the ice-water interface. This is in accordance with the density graph, which shows that between 0 °C and 4 °C, the colder the water, the less dense it is.

The next set of figures (3-5) represent the flow when density inversion is present. The circulation pattern inside the enclosure now consists of two counter-rotating cells. The clockwise cell on the left side is the dominant one since the temperature range below the maximum is twice the temperature range above it. The fact that the small cell on the right does not extend all the way to the top is due to viscous effects.

The last set of figures (6-8) corresponds to a more balanced thermal boundary condition inside the liquid phase. The left boundary is simply the ice-water interface which is at 0 °C, and the right boundary is at 8 °C. This provides for a certain level of symmetry which can be seen in Figures 6-8. The two counter-rotating cells are still of approximately equal size after 5000 time steps. After 10,000 time steps (Figure 7), however, the cell on the right is now confined to the lower right corner. The loss of symmetry in the flow pattern can be explained by the fact that the isotherms are no longer vertical. This is due to the effect of fluid flow on enthalpy, and therefore on the temperature field. This is even more pronounced after 15,000 time steps, as can be seen in Figure 8.

Nanofabrication and Resistance Testing of Metal Coated Silicon Microcontact Arrays

Jeffrey A. Yap

Materials Science and Engineering
Cornell University
Bard Hall, Ithaca, NY 14853

Faculty Advisor:

Prof. Jack M. Blakely

It has been proposed that an array of pointed tips on one side of an electrical interface will reduce the load required to obtain sufficiently low resistance for microchip testing contacts. The purpose of this project was to fabricate an array of pointed silicon columns, coat them with a layer of tungsten metal, and test the resistance across the contact with a metal probe. Data revealed that the electrical contact through the pointed surface achieved low test resistances at lower loads than the contact through a flat surface.

BACKGROUND

Semiconductor research is always directed at making computers smaller, faster, and more powerful. One of the next possible advances in computer technology will come in the form of modules and nanotechnology. Modules are bundles of pre-packaged microchips hardwired together to minimize the distance for an electrical impulse to travel. Researchers who work in the area of nanotechnology are searching for lithography techniques and procedures that will provide increasingly small features on the chip circuitry. But with both of these innovations, the current method of chip testing has become obsolete. Modern testing uses small probes that press down on contact pads and test the voltage across the circuits. But with the smaller features requiring more testing contacts and the need for pre-packaged testing, the load increases while the area decreases. The resultant pressure will cause the chip to fail. It is believed that an array of pointed tips that could be fabricated onto the testing probes or onto the microchip contacts could reduce the load required to make an adequate testing contact. These pointed tips would provide a reproducible low impedance contact by minimizing the asperitic effects, and piercing any oxide or contaminant layer on the surface of the probe. This report will describe the tip fabrication process and document the results of the resistance testing.

EXPERIMENTAL METHODS AND MATERIALS

The arrays of tips were fabricated using photolithography, selective ion etch and metal deposition techniques. All fabrication steps were conducted at the Cornell Nanofabrication Facility (CNF). Silicon wafers were obtained that had an 800 Å oxide layer. The wafers were hexamethyl disilane vapor primed in the YES oven for 34 minutes. Shipley 1813 was then spun onto the wafers at 4000 RPM for 60 seconds. After spinning, the wafers were baked at 115° C for 60 seconds. The wafers were then exposed for 0.6 seconds on the HTG contact aligner using a chrome on glass mask. The mask had two areas that were two dimensional clear field arrays of dots with different periodicities, and a third area was a two dimensional dark field array of holes. After exposure, the wafers underwent a post-exposure bake and were developed in MF 312. After developing, the two clear field arrays generated dots of resist while the dark field array generated holes.

The pattern of dots of resist on the wafer was used in a selective etch process to etch the oxide layer, which was then used to selectively etch the silicon substrate. A Plasma-Therm 72 reactive ion etcher was used for these processes. The wafer was descummed using an oxygen plasma, then the oxide layer was etched using tri flouro methane and oxygen. The oxide etch removes oxide at 325 Å per minute. After etching the oxide, the resist was completely removed in an oxygen plasma. Lastly, the silicon was etched using a sulfur hexaflouride and oxygen etch recipe. This etch is anisotropic and etches silicon versus oxide in a 6.5 : 1 ratio. Therefore, the etch undercuts the oxide layer, forming pillars with sloped sidewalls. By varying the gas concentrations and the etch times, varying shapes and heights of columns were produced. A higher oxygen percentage causes the plasma to etch downward more than sideways, producing

BEST COPY AVAILABLE

steeper sidewalls and a higher aspect ratio between height and width. After the etch was completed, the wafers were dipped in hydroflouric acid to remove the rest of the oxide layer.

Metal deposition was conducted in a CVC sputtering chamber. This was the chosen method because chemical vapor deposition of tungsten requires a very high temperature, and was not possible at the CNF. Tungsten metal was chosen to be the surface metal due to its hardness and low resistance. The wafers were placed in the vacuum chamber, ion beam cleaned, and coated with approximately 350 nm of tungsten. The wafers were then removed, the contact pads painted over with resist, then placed back in the sputtering chamber to be ion beamed and coated with copper. This copper coating adhered to the tungsten and allowed wires to be soldered to the area around the contact pads. Then the resist was removed and the tungsten on the tips was exposed. An SEM micrograph of the finished tip array is shown in Figure 1.

The contact arrays were tested on a contact resistance tester in the Cornell University Materials Science department. Gold hemispherical probes were fabricated by melting the end of a gold wire with an acetylene torch and allowing the end to ball up due to surface tension. These probe tips would prevent error due to misoriented contact. The resistance tester places a voltage across the contact, and measures the current as a function of increasing load.

ANALYSIS

The data from the contact resistance tests on the fabricated array was compared with a similar resistance test on a flat surface. (Figure 2) It can be seen that the load required to obtain a particular resistance is lower for the contact array than for the flat surface, or equivalently, the resistance is lower for the tip array than for the flat surface at the same load.

A second series of wafers have been fabricated with sharper points to try and further reduce the resistance of the contact. It is hoped that an optimum size and dimension for an array of pointed tips can be found that will bring the load and resistance to a minimum.

CONCLUSION

In order to test smaller, more closely packed electronic chip features, a method of reducing the load required to achieve sufficient electrical contact must be found. It has been demonstrated that a fabricated array of pointed tips on one of the surfaces reduces the resistance across the contact. Arrays were fabricated that attained a low resistance at lower forces compared to a flat surface. Research is currently being conducted to try and find the optimum size and dimension of pillars that will achieve the lowest resistance for low loads.

ACKNOWLEDGMENTS

This research was made possible by a grant from the National Science Foundation, and was conducted at the Cornell Nanofabrication Facility and the Cornell University Materials Science Center.

The Effect of Razor Notching Techniques on the Fracture Toughness of Polymeric Materials

Dora C. Arevalo

Department of Mechanical Engineering
Texas A&M University-Kingsville
Kingsville, TX 78363-8202

Faculty Advisor

Dr. Carlos R. Corleto

The objective of this research is to find the effects of different razor notching techniques on the fracture toughness values of brittle and ductile polymers. Three brittle polymers are tested, polycarbonate, PMMA, and Lexan. PVC is the only ductile polymer being tested to date. A modified razor blade with teeth (thus resembling a saw) is being used to induce a stress free crack tip as opposed to the use of a regular razor blade suggested in the ASTM 5045-91A standard. Photo-elastic observations show that the crack tips of polycarbonate are virtually stress free when the modified blades are used. Also, it can be observed that using the modified blade gives more conservative fracture toughness values for PMMA, and it also reduces the variability in the results. The effect of the modified blade on PVC is being studied.

INTRODUCTION

Fracture toughness is the ability of a material to resist crack growth when it is loaded in tensile mode. In ductile polymers this material property is equivalent to the J-integral. Currently, the ASTM D5045-91A standard is used to evaluate this material property in brittle polymers. However, no standard exists to evaluate the J-integral in ductile polymers since, due to the viscoelastic behavior of these materials, it is very difficult to determine when the crack growth starts. Due to the notching method described in the ASTM D5045-91A standard (in the case of the brittle polymers) it is suspected that some error is introduced before testing that results in values that are either too high or too low. Therefore, the objective of this research is to test new notching methods that will induce crack tips resembling as much as possible a natural crack which in turn will reduce the error in the fracture toughness values found. For brittle polymers fracture toughness is calculated with the following formula:

$$K_{IC}=(P_Q/B)\cdot W^{1/2}\cdot f(x) \qquad (1)$$

P_Q = maximum tensile load W = width of specimen
B = specimen thickness $f(x)$ = function of a (the initial crack length)

For ductile metals the J-integral is calculated in the following way:

$$J = A\cdot n/B_n\cdot b_0 \qquad (2)$$

A = Area $n = 2+0.522\cdot(b_0/W)$
B = Specimen thickness b_0 = uncracked ligament

NOTCHING METHOD

The notching method proposed is a modification to the one described in the ASTM 5045-91A. It consists of using a serrated blade as shown in Figure 1, and creating the final notch with the use of a shaper machine. The use of the shaper machine creates the final notch in a sawing motion at a constant rate, and it controls the length of the final notch on all specimens. The idea behind using a serrated blade was to try to minimize the stresses created around the crack tip radius as well as decreasing the crack tip radius. This method was applied to all brittle and ductile polymers tested.

TESTING PROCEDURE

Compact test specimens were used with the dimensions shown in Figure 2. Three sets of ten specimens were tested for each brittle and ductile material. Five specimens were notched using the modified blade, and the other five using the regular blade for comparison purposes. The final crack tip which is 0.025 in. was created using a shaper machine. The shaper machine created this final crack at a constant rate and allowed to control the length in all specimens. Polycarbonate samples were viewed under a polariscope. The polycarbonate, polymethyl-methylacrylite, and Lexan specimens were loaded to failure in order to calculate the fracture toughness value. The polyvinylchloride samples were tested using the multiple specimen techniques.

CONCLUSION

Polycarbonate was the first material tested due to its photo-elastic properties. Using the modified razor blade on polycarbonate revealed that virtually no residual stresses were present after the notching whereas the regular blade produced highly visible stresses around the crack tip (see Fig. 4). In addition, an analysis with a scanning electron microscope (SEM) revealed that the crack tip radius was smaller for the modified blade compared to the regular blade. From Table 1 it can be seen that in the case of PMMA the fracture toughness values and the standard deviation are lower when the specimens are notched with the modified razor blade than with the regular blade. In the case of Lexan, there is not much variation in the fracture toughness and standard deviation values. These results suggest that every polymer is affected differently depending on the notching method used. In the case of PVC the J-integral values vs. crack growth reveal very similar trends when either the serrated of regular blade is used. However, more testing has to be done on PVC to settle the issue.

Structural laminated composites are being identified for implementation into new generation launch vehicles. There is an increased need to fully understand and predict the failure criteria of these materials, as it is crucial to the success of NASA's current and future goals. There now exists many computer programs which predict the failure of these materials using the finite element technique. However, assumptions about the in-plane strength of composite laminates cause tremendous error in the computer-produced predictions. The objective of this project is to show the errors in these assumptions, proving that the lamination theory is incapable of correctly predicting the failure of composite laminates.

INTRODUCTION

The need for safe, lightweight, less expensive, and more reliable launch vehicle components is being driven by the competitiveness of the commercial launch market. The United States has lost two thirds of the commercial launch market to Europe. As low cost Russian and Chinese vehicles become available, the United States market share could be reduced even further. Additionally, reliable and inexpensive transport to the international spacestation during construction and operation will be critical to its success. This international climate is driving the NASA Reusable Launch Vehicle (RLV) Program. The objective of this program is to make routine transportation to and from space with a totally reusable launch vehicle that has aircraft-like operation designed to reduce the cost per launch by a factor of 10. Achieving this objective will require more efficient uses of materials.

Continuous fiber reinforced plastic (CFRP) composite materials can provide the NASA RLV Program with the material and structural efficiencies needed to stay competitive in the international launch market place. Composite materials offer high specific properties (material property/density) that can significantly reduce the weight associated with launch vehicles. This reduction leads to increases in payload capacity, and reductions in propellant requirements.

In satellite systems, the high specific properties, design flexibility, improved corrosion and wear resistance, increased fatigue life, and low coefficient of thermal expansion that are characteristic of CFRP composite materials can all be used to improve the overall satellite performance. Some of the satellites that may be able to take advantage of composite materials are the Tethered Satellite Systems (TOSCIFER, AIRSEDS, TSS2, SEDS1, AND SEDS2), AXAF, GRO, and the next generation Hubble Space Telescope.

The advantages of CFRP composites material are seldom fully realized because of their inherent complexity and the limited understanding of their fundamental behavior. As a result most composite structures are over-designed, a luxury that the RLV program can not afford.

There now exists many computer program which attempt to predict the failure of composite materials. These programs are based on the classical lamination theory which uses a series of matrix manipulations to determine the failure of a composite laminate. However, this method fails to consider the rich three-dimensional stress states of a multi-ply composite, constraint of adjacent plies, and the statistical nature of the material. L.J.Hart-Smith points out that the current methods of failure prediction are not based on physical phenomenon and fail to consider the micromechanics of composite materials. Many of computer programs now available are being used without concern to their validity. Experimental observation revealed that the computer programs fail to take into account the micromechanics and ply-interaction activities within the composite and therefore, error is present in the prediction of failure criteria.

The remainder of this paper shows that current composite programs are incapable of correctly predicting failure in composite laminates. First, the methodology for this investigation is explained which is followed by a summary of the results gathered from both experimental and theoretical means. Results are then discussed and conclusions stated.

METHODOLOGY

This project used prepreg tape with IM7 fibers embedded in 977-2 epoxy matrix at a volume fraction of 0.6. 12" by 12" square sheets of prepreg material were hand laid up and hot pressed cured. The plates were then cut into 1.5" wide by 12" long specimens. End pieces were not used.

The preliminary specimens consisted of eight individual layers of the carbon fiber/epoxy resin sheets arranged in unidirectional $[0]_s$, ninety degree $[90]_s$, and $[\pm 45]_s$ lay-ups. These specimens were used to generate material characterization data for input into computer models. Six to eight replicates of the specimens were prepared in order to produce statistically significant values for Poisson's ratio, Modulus of Elasticity, and breaking strength. Table 1 shows the results of the preliminary tensile tests. A second set of specimens were prepared for the purpose of observing an onset of failure and the ultimate laminate strength. Three geometry's were used: quasidirectional 1($[+45/0/-45/90]_s$), quasidirectional 2 ($[-45/0/+45/90]_s$), and bidirectional ($[0/90]_s$). These specimens were also hand-laid up and hot press cured. The width of these specimens were 1.5" and their length was 12".

Table 1: Material Characterization Experimental Results

SPECIMEN	REPITITIONS	ULTIMATE BREAKING STRENGTH (PSI)	MODULUS OF ELASTICITY (MSI)	POISSON'S RATIO
$[0]_s$	8	320,000	26.65	0.3342
$[90]_s$	6	7,360	1.62	0.0246
$[\pm 45]_s$	6	38,200	1.66	-

Experimental materials characterization was performed on a 100 kip Servo hydraulic Instron in stroke control. Biaxial strain gages were placed on the specimens in order to determine values for Poisson's ratio. Strain gages on each face of the specimen were used to check for out-of-plane bending. Failure analysis data was generated using ten specimens of each quasidirectional 1($[+45/0/-45/90]_s$), quasidirectional 2 ($[-45/0/+45/90]_s$), and bidirectional ($[0/90]_s$) composite laminates. Each specimen was taken to failure to determine a statistically significant ultimate breaking strength. Additional laminates were then loaded to 20%, 50%, and 90% of the ultimate breaking strength. The specimens were then unloaded and removed from the load frame and subjected to various non-destructive tests (NDE) techniques in order to determine the mode of damage present. Table 2 is a summary of the failure analysis.

Table 2: Failure Analysis/Experimental Results

SPECIMEN	BREAKING LOAD (ksi)	LOADED TO 90% OF BREAKING STRENGTH
Quasidirectional 1 $[+45/0/-45/90]_s$	122.2	Edge delamination No 90 degree cracking
Quasidirectional 2 $[-45/0/+45/90]_s$	137.9	No edge delamination No 90 degree cracking
Bidirectional $[0/90]_s$	145.6	No edge delamination No 90 degree cracking

Both X-ray analysis and microscopy were used to examine the in-plane layers of the composites for the presence of damage. A zinc iodide solution was placed on the edges of the composite laminate and was allowed time to seep down into the specimen to enhance the visibility of cracks. The specimens were then exposed to X-rays using a HP Faxtron and Kodak type 55 film. This method reveals matrix cracking both in and out of the plane of the laminate. The second method used to examine the failure modes in the composite was microscopy. Each specimen was cut into small pieces and then meticulously polished. The polished edge was then placed under a microscope where any damage could be viewed.

Using the information gathered from the preliminary tensile tests, the Composite Pro® computer program, as well as finite element analysis, was used to predict the failure criteria of a quasidirectional lay-up carbon epoxy laminates. Properties of the carbon IM7 epoxy matrix 977-2 gathered from the preliminary tensile tests were used as input for the program in order to calculate the failure modes of the quasidirectional lay-ups. The computer programs predicted the ultimate breaking strength as well as the load at first failure. Table 3 is a summary of the results from the computer modeling.

Table 3: Results from Computer Modeling

SPECIMEN	FIRST FAILURE PREDICTION (ksi)	BREAKING LOAD (ksi)
Quasidirectional 1 $[+45/0/-45/90]_s$	20	130
Quasidirectional 2 $[-45/0/+45/90]_s$	30	140
Bidirectional $[0/90]_s$	40	150

DISCUSSION

Many current computer codes are not capable of correctly predicting the failure of composite laminates. The failure of carbon fiber IM7, epoxy matrix 977-2 composites were experimentally investigated. Experimental materials characterization was performed on $[0]_s$, $[90]_s$, and $[\pm45]_s$ specimens which laid the foundation for input into the computer programs.

Composite laminates can experience two main modes of failure: Intralaminar damage and/or interlaminar damage. Intralaminar damage occurs within the plane of the specimen and shows up in the form of small cracks running transverse to the fibers within the layers of the composite. Interlaminar failure, on the other hand, consists of debonding between the plies of the specimen (commonly termed delamination).

Intralaminar damage occurs as a result of stress on the composite and shows up as cracking within the layers of the composite. First failure, in the form of transverse cracking, commonly occurs within the ninety degree layers of the specimen due to the weakness of the ninety degree plies. The computer programs predict this cracking to occur at a load of approximately 20% of the breaking strength of the laminate. When pulled to ninety percent of breaking, neither the quasidirectional or bidirectional specimens show evidence of cracking.

Interlaminar damage occurs at the edges of the composite in the form of

BEST COPY AVAILABLE

debonding between the plies. This type of failure is evident in the quasidirectional 1 specimen at a load of 90% of failure. However, the computer programs fail to predict the delamination of the composite laminates because it assumes that each layer of the composite is allowed to act freely and individually. Boundary conditions are not accounted for by the computer programs.

Experimental failure analysis was performed on $[+45/0/-45/90]_s$, $[-45/0/+45/90]_s$ and $[0/90]_s$ specimens as shown in Table 2. The experimental failure ranged from 122 ksi to 146 ksi. There were signs of debonding between the plies of the specimen (delamination) at loads above 90% of breaking. However, there were no signs of cracking within the individual layers of the composite laminate for any of the different lay-ups.

Computer modeling of quasidirectional and bidirectional specimens is summarized in Table 2. Shown in this table are predictions of breaking load and first failure. Breaking was determined to occur at loads ranging between 130 and 150 ksi. Evidence of first was failure was predicted to occur at fairly low loads, 16%, 21%, and 26.6% of breaking for quasidirectional 1, quasi 2, and bidirectional specimens respectively.

The three dimensional stress states and intralaminar stress are not being accounted for by the computer programs. Evidence of this failure is seen in the experimental results as debonding occurs at the edges of the composite but are not predicted by the computer programs. Boundary conditions, such as layers upon layers, do not allow for the individual layers of the composite to act freely and individually. The computer programs do not take boundary conditions into consideration which allows for incorrect failure predictions.

CONCLUSIONS

Contrary to the program predictions, failure was not evident in any of the layers within the composites. The failure sequence and mechanisms are shown to be incorrectly predicted by the current computer models. Furthermore, the computer programs fail to take the interaction of boundary layers into consideration and therefore, can not predict the presence of delamination in a composite laminate. In order to achieve optimal failure criteria predictions mircomechanics must be employed into the computer programs.

The Design and Development of a Phantom Model for Hyperthermia Cancer Treatment

Jennifer Lelas

Department of Mechanical Engineering
Union College
807 Union Street
Schenectady, NY 12308

Faculty Advisor:

Ann Anderson

The goal of hyperthermia therapy is to raise the temperature of a tumor above 42°C. One clinical problem resulting from the lack of understanding of the mechanisms of bioheat transfer is the difficulty in determining when the tissue has reached 42°C. Phantom models are tissue-equivalent materials used to study bioheat transfer and the resulting temperature distribution.

Three phantom models were designed for studying the temperature distributions incurred by simulated hyperthermia therapy. One is used to study only conduction through the surrounding tissue; one has a straight tubing array to simulate convection due to arterial vessels; while the third mimics capillary perfusion using a simple tubing network. The temperature distributions in each phantom were measured using liquid crystal thermography. Liquid crystal color patterns were apparent when the model was heated within the active range and were recorded by photography. The results were compared to better understand the effect of blood flow.

BACKGROUND

The goal of hyperthermia cancer treatment is to raise the temperature of a tumor to toxic levels, above approximately 42°C (106°F), while keeping the surrounding healthy tissue at normal temperatures. This treatment is based on the fact that temperatures of 42°C or higher can kill mammalian cells.(1) Hyperthermia therapy is often used in conjunction with radiation or chemotherapy. In fact, hyperthermia has approximately doubled the effectiveness of x-ray therapy against melanoma and breast cancer (Hayashi 1993).

There are three modes of hyperthermia cancer treatment. The first is whole-body hyperthermia where the object is to raise the temperature of the entire body to therapeutic temperatures. The advantage of this method is apparent in systemic cancers where the treatment is not local to a specific tumor (Strohbeln 1986), as with other types of therapies, but system-wide.

The second mode is regional hyperthermia therapy. During this treatment, energy is deposited to the general region of the tumor (Strohbeln 1986). The problem with this modality is sustaining the healthy tissue at normal temperatures while achieving toxic temperatures within the tumor itself.

The final type of hyperthermia therapy is local hyperthermia. Here the energy is deposited in the tumor itself with minimal amounts extending to the surrounding tissue (Strohbeln 1986). The difficulty with this is that the tumor must be extremely localized and its boundary well-defined.

Heat can be applied in several ways. The most common are electromagnetic microwave frequencies of 300-2450 MHz, radio frequencies of <300 MHz and ultrasound at frequencies of 0.3-3 MHz.(1) There are two methods of applying hyperthermia treatment: superficial and interstitial. Superficial hyperthermia treatment heats tissue from zero to five centimeters in depth to a temperature of 42°C using an array of heat applicators set up outside of the body (Hayashi 1993).

The second type is interstitial hyperthermia treatment. The heat is delivered to the tumor site by implanted devices. Early techniques used metallic implanted needles. Now, microwave hyperthermia treatment consists of implanted plastic catheters holding a microwave antennae. Also used for heating are interstitial laser and interstitial conductive devices such as ferromagnetic implant seeds, electrical resistance elements and hot water tubes (Hayashi 1993).

The mechanisms of cellular damage after hyperthermia therapy to both healthy and tumorous cells are multiple, complex and poorly understood (Green 1991) and there is no consensus to the importance of each (Perez et. al. 1987). It has, however, been observed that tumors are more heat sensitive than healthy tissue (Pethig) and this is a testament to the theory behind hyperthermia cancer treatment. However, the most important factor in the heat transfer aspect of hyperthermia is the decrease in the blood flow rate within the tumor. The increased growth rate of the tumor creates pockets of cells, or buds (Report on Research 1987-88). The blood flow through these pockets is not as effective due to the random fusion of elongated, dilated, and twisted blood vessels (Perez et. al. 1987). This makes the pockets less susceptible to blood-borne drugs and radiation and more likely to be damaged by heat (Report on Research 1987-88) because they cannot dissipate the applied heat as efficiently as normal tissue (Lagendijk 1984). However, tissue temperature is extremely sensitive to convection due to blood flow; therefore, any large vessel within the tumor will cause a lowering of the minimum tumor temperature. These locations will be under dosed and the tumor will regrow from there (Lagendijk 1984).

One method used by researchers to study heat transfer and resulting temperature distributions is provided by phantom modeling. Phantoms are electromagnetic tissue-equivalent physical materials with bulk electrical and thermal properties similar to those of human tissue (Baish et. al. 1986), the latter being the more difficult to model due to blood flow heat transfer effects (Perez et.al. 1987). The use of phantom models are well established in hyperthermia research (Baish et.al. 1986). However, their use is restricted by the limited number of blood flow patterns available and the difficulty in simulating live tissue (Lim 1988).

Although phantoms have a flow geometry very different from the microgeometry of tissue, they do provide a well-controlled system for examining some fundamentals of bioheat transfer (Roemer 1991). Some examples of phantom models include: dielectric liquids, sponges soaked in saline, mixtures of "superstuff" (polyethylene powder, salt and water), saline-formaldehyde gels, beef, and live animal tissue. There are two distinct types of phantom models: static and dynamic. Static phantoms account only for conduction heat transfer and not convection by blood flow (Perez et.al. 1987). An example of a dynamic model is a solid matrix of tissue-equivalent electromagnetic material in which parallel tubes are embedded. Water is passed through the tubes to simulate the convective cooling effects due to blood flow. A high flow rate ensures that a constant temperature is kept along the tubes. The difference in the temperatures between the tubes and the simulated tissue represents the difference between artery and tissue temperatures respectively (Baish et.al. 1986). The biggest problem facing phantom modeling is simulating the complex microvasculature of the human body (Pethig).

EXPERIMENTAL SETUP

The purpose of this project was to design and construct a phantom model to study the bioheat transfer mechanism. The temperature field calculated using the bioheat transfer equation will be compared to that measured experimentally in the phantom.

Three phantoms were constructed for laboratory experiments. All three were made from a polyacrylamide gel held in a 10"x8"x3" plexiglas container. The gel was covered during storage and testing to prevent it from drying out. Figure 1 shows a schematic of the phantom model and its layers. Each model was constructed using an approximately one inch thick layer of gel on the bottom of the plexiglas container. Two liquid crystal sheets were placed side by side on top of the gel to obtain readings in both the 35-40 degree Celsius range and the 40-45 degree Celsius range. Another one inch layer of gel was placed on top of the liquid crystal sheets. The heating elements were placed every two and one-half inches down the center of the phantom to simulate interstitial hyperthermia. As the phantom was heated, the resulting temperature pattern on the liquid crystal sheets was recorded through the transparent gel by photography.

The dynamic phantom, which simulated large arterial blood flow, contained two parallel tygon tubes (three inches apart). These were embedded within the bottom layer of the polyacrylamide gel in an attempt to duplicate the perfusion effects of arterial flow. The third model simulates capillary blood flow by embedding a network consisting of branching segments of glass tubing instead of the tygon tubing.

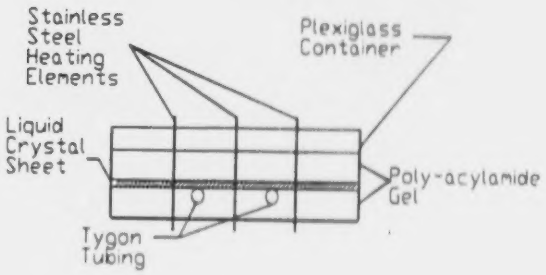

Figure 1: Schematic of Phantom Model

TESTING PROCEDURE

Hyperthermia treatment was simulated by applying a voltage drop across each of the three stainless steel elements implanted into the gel. The current through the wires was 5 Amps while the voltage across each rod was found to be averaged about 0.468 V, resulting in a total voltage of 1.404 V. The total power supplied to the system was approximately 7 Watts, assuming no losses through the lead wires. This power level was determined through trial and error. A higher current burns the polyacrylamide gel, while a lower current will not yield enough energy to reach toxic temperatures.

Tests were run for twelve hours until steady-state was reached. Photographs were taken at distinct time intervals throughout the testing to obtain transient temperature patterns of the liquid crystal sheets. Photographs were also taken once the phantom had reached steady-state. An example of the data obtained is shown in Figure 2.

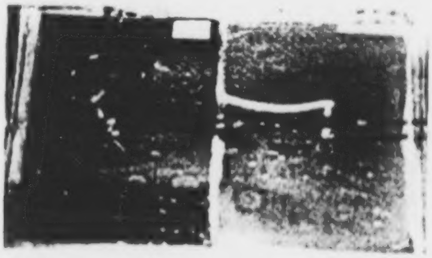

Figure 2: Temperature Distribution Patterns on 35-40 degree Celsius (right) and 40-45 degree Celsius (left) Liquid Crystal Sheets

RESULTS

Figure 3 is a contour graph obtained from the static model. The right side shows the 35-40 degree C liquid crystal sheet; while the left shows the 40-45 degree C liquid crystal sheet. The red start, corresponding to 35°C and 40°C respectively, is indicated by the solid lines; the green start (36,41) is indicated by the dashed lines; and the blue start (40,45) is depicted by the dotted lines. The heat transfer due to conduction alone is shown from (2a) to (2c) as the heat from each heating element begins to interact and spread throughout the gel.

Figure 4 is a contour plot of the dynamic model. The test conditions were the same as they were for the static model. However, water was flowing through the tubes. The figure shows however, a distinct cooling affect due to the "artery" passing through the gel at the locations depicted by the arrows. The convection heat transfer occurring in these locations lowers the temperature of the gel and results in a lower overall temperature reached by the simulated therapy.

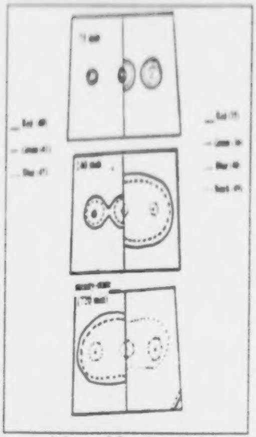

Figure 3: Contour Map of Static Model after (top) 75 min; (middle) 240 min; and (bottom) steady-state.

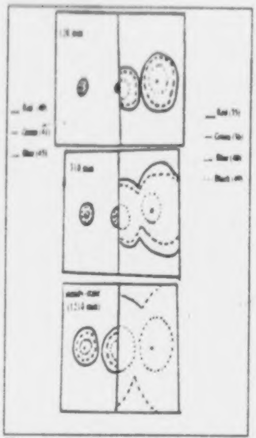

Figure 4: Contour Map of Dynamic Model after (top)120 min; (middle) 310 min; and (bottom) steady-state.

CONCLUSIONS

When comparing Figures 3 and 4, the overall lower temperature resulting from the "artery" running through the tumor is apparent. This, in a clinical situation, could possibly nullify the effect of the treatment since toxic temperatures were not reached throughout the tumor. The tumor can regrow from those cells not damaged and killed during therapy and the disease could spread. This type of analysis is very important is understanding the effect of blood flow in tumors located near large arterial blood vessels and also must be done to understand the effect of capillary perfusion effects in all tissue. Until these bioheat transfer mechanisms are understood, hyperthermia treatment will continue to be theoretically sound but clinically a "trial and error" type of treatment.

ACKNOWLEDGEMENTS

The author wishes to express her appreciation to Professor Mary Carroll for her assistance in preparing the polyacrylamide gel for the each of the three phantom models.

International Virtual Design Studio:
Design of a Vehicle Without Wheels or Wheel-like Contact With the Floor

Faculty Advisor:

Ronald B. Bucinell, Ph.D., P.E.

With the emerging global environment, the requirements of today's engineers are expanding rapidly. Today engineers must be able to collaborate with their colleagues around the world. In response to this new demand, the idea of the International Virtual Design Studio (IVDS) emerged. The IVDS is a joint project between Union College in Schenectady, NY and the Middle East Technical University in Ankara, Turkey. The eight participating students communicated via current internet technologies to design, manufacture, and test a competition vehicle. The project culminated with the Union students traveling to Turkey to submit their vehicle and compete in the day-long class competition. This paper introduces you to the concept of the IVDS (one of the first in the world) and explores both the design process and the design itself, the wheel-less vehicle, in the context of the IVDS.

INTRODUCTION

The last decade has seen an explosion of new technology that has enabled the exchange of information on a world-wide scale. Mirroring this new trend, both large and small engineering firms are increasingly drawing upon the resources of the international community for their expertise and unique perspective. Thus, to prepare future engineers, undergraduate training should have some international component. The objective of this project was two-fold. First, it served as a pilot project to gauge the feasibility of a collaborative design experience between students in remote locations. Second, it gave the students a valuable, international design experience in which they communicated with the students in Turkey to design, construct, and test a vehicle that can successfully compete against other vehicles in the competition.

The idea for the International Virtual Design Studio emerged from a series of three unrelated events. First, an electrical engineering alumnus, returning to Union, explained how his electronics firm had just hired two new engineers, both of whom resided outside of Washington, DC where the firm was located. These new engineers remained in their respective locations and used electronic technologies to communicate with the firm. Second, the idea of a "virtual term abroad" was proposed by a faculty member from Union's East-Asian Studies Program to bring Union College students and students in Asian universities together. Finally, in the spring of 1996, Richard A. Kenyon, Dean of Engineering at Union College, traveled to the Middle East Technical University (METU) in Ankara, Turkey and discussed the possibility of an exchange program between METU and Union College. The idea for the IVDS project was proposed to Dean Platin, Associate Dean of Engineering at METU, who communicated an interest in such a project.

Mechanical engineering students at Union College complete a two-term (20 weeks) capstone design project in their senior year. At the Middle East Technical University, senior mechanical engineering students participate in a similar 16 week-long design competition. The similar project objectives and time frames made a collaborative design project between the two schools feasible. Four Union College students and four METU students were selected. In the spring of 1996, the two students that initially volunteered began to investigate current internet technologies for the project and to design the studio. Their research and work resulted in the pilot design studio shown in Figure 1. The Union College students used this room to communicate with their Turkish partners. Note the large computer screen and curved setup to accompany up to four students. By the beginning of the fall term, the two teams had been formed from the eight students.

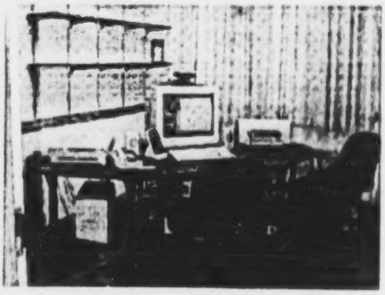

Figure 1: The pilot IVDS room at Union College

The remainder of this paper will discuss the pilot IVDS project. First, the project and competition guidelines is given and then the design and manufacture of the vehicle is discussed. This paper concludes with an overview of the competition.

THE PROJECT

The project assignment was to design a vehicle with no wheels or wheel-like motion to travel down a 30 cm wide path while carrying a minimum payload of 500g. There were two tests during the competition and points were accumulated based on five criteria. In the first test, the objectives were to: (1) maximize the traveling distance in one minute, (2) minimize deviations from predicted values, (3) minimize the energy consumption, and (4) minimize the weight of the machine. In the second test, the objective was to maximize the payload carrying capacity (payload/machine weight). Each side had to manufacture and test their own vehicle and then one machine was be submitted for the competition.

The project was divided into three phases: design, manufacturing, and competition. The first phase involved the design of the vehicle and submission of the design report at the end of the first six weeks. During this phase, the students communicated several times a week over email and through occasional telephone calls. The first step in the design process was brainstorming which was made possible by exchanging pictures of ideas. At this point, all ideas were considered possible design solutions. The students conceived of a hovercraft, an electromagnetically-driven vehicle, a spider-like walking machine, a pushing-motion machine, and a rowing-motion machine. A literature survey was then conducted to investigate past solutions to wheel-less vehicles. Next, a feasibility study was conducted. In this study, each brainstorming idea was critically weighed against the five competition criteria and rated according to how well it could fulfill each criteria. The students also considered the simplicity of each idea, the ability to manufacture, and the availability of standard parts. The pushing-motion machine was chosen for its simple design, reproducible motion, low weight, and its ability to be easily manufactured.

The basis for the pushing-motion machine is a Grashof crank-rocker mechanism that transforms the constant circular motion from the gearbox to a rocking motion. Two legs were used to translate the rocking motion into pushing-motion. Each of the two legs was attached to a foot which would grip the floor and allow the vehicle to be propelled forward. To design the linkage a cardboard model was first constructed to obtain the desired motion and approximate link lengths. Then the link lengths were found analytically. Both the cardboard model and the analytical method resulted in surprisingly similar link lengths. The gearbox was designed to increase the torque and decrease the output speed from the 12V DC motor. The design report consisted of a literature survey, feasibility study, detailed design drawings and calculations, performance values, and was assembled by both the Turkish and American students. Considerable attention was given to the predicted values because points were accumulated based on how well the actual performance values were predicted in the design report.

The next phase in the project was the manufacturing stage. This phase was ten weeks long to ensure sufficient time to obtain supplies and parts, manufacture, test, and make necessary changes. During this time, the students did not correspond as frequently as during the design stage. Communications focused on problems encountered and changes that needed to be made. By the ninth week, the Union vehicle was ready for testing. Several minor modifications were made to optimize the motion and payload carrying-capacity.

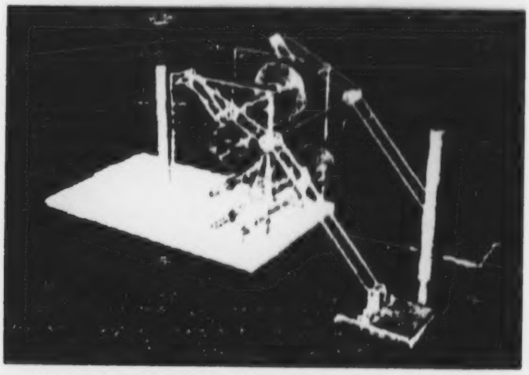

Figure 2: The pushing-motion vehicle with the payload located to the left, the gearbox in the center, and the load-carrying feet at the right.

The final phase of the project took place at the Middle East Technical University from January 27 through January 30, 1997. The four Union students and their advisor, Assistant Professor Ronald Bucinell, arrived in Ankara on Monday, January 27. They were immediately taken to the school where the students met their partners and were given two hours to compare vehicles and decide which one to submit. The author's team chose the U.S. vehicle because it weighed less, traveled faster and farther, and carried more weight. The next day was for a jury presentation. Each team demonstrated and defended their car in front of several professors and graduate students. The teams had to answer questions about why they chose their particular design and they also had to explain differences between the two vehicles.

The competition was held on Thursday January 30, 1997 in an atrium of the mechanical engineering department. Both IVDS teams competed against approximately 17 other teams. Though only the U.S. car competed in the competition, performance values were obtained for both cars.

RESULTS

The table below summarizes the predicted values and performances values for both the U.S. and the Turkish cars.

	Predicted	Turkey vehicle	U.S. vehicle
Weight (gm)	470	820	580
Load carried (kg)	1.25	1.25	1.25
Distance traveled in one minute (cm)	250	220	385
Power (W)	4.11	4	4

DISCUSSION

One of the underlying objectives of this project was for the two groups of students in the United States and in Turkey to design and construct similar vehicles which could indicate the level of collaboration between the two teams. However, to produce two vehicles with the same performance characteristics is a formidable task. The team in the U.S. and the team in Turkey did not have the same access to materials and manufacturing expertise. For instance, in Turkey, many of the teams machined their own gears whereas in the U.S. it was decided they would be purchased from a supplier. Also, the Turkish students had to manufacture their vehicle themselves with limited shop experience and time. However, the U.S. students were not trained nor allowed to use their machine shop. Thus, they relied on professional machinists. Therefore, many of the differences between the vehicles could be attributed to these factors.

The performance values obtained from the two vehicles built by Team 2 can provide some insight into how well the objectives of the project were fulfilled. The similar performance values between the U.S. and the Turkey vehicle indicate that the teams communicated well, particularly during the manufacturing stage when many last-minute changes were made to the vehicle.

The international nature of this project earned it the nickname of the "Virtual Term Abroad." This name may suggest that it is similar to a standard term abroad experience. However, there is an important characteristic that distinguishes a standard term abroad experience from the IVDS project. When a student studies in another country they are experiencing the culture and education firsthand. Since they are immersed in the culture, they can easily gather valuable cues and signals from students and professors regarding expectations, work ethics, and beliefs. However, in a project such as the IVDS, where the students remain in their respective countries for most of the project, the students cannot easily learn the cultural practices and beliefs that may become an important factor in working as a team. Participants should be aware of this missing component so they can still be sensitive to the culture they are working with and make a concerted effort to learn about the culture through other avenues.

CONCLUSION

The IVDS pilot project at Union College offers a unique chance for students to interact with students around the world using current internet technologies. It is a particularly challenging project because though the students remain in their respective countries for most of the project, it requires they make a concerted effort to learn about the other culture. The lessons learned in working with students from other countries can be applied to situations that the engineer will encounter in the academic and industrial workplace. Since the project is academic in nature, it forces the students to draw upon and apply their engineering coursework. Thus, this project gives the students a significant foundational experience in collaborative design from which they can build upon after graduation.

Heat Transfer Enhancement on a Printed Circuit Board

Gretchen R. Voegler

Department of Mechanical Engineering
Union College

Schenectady, NY 12308

Faculty Advisor:
Ann M. Anderson, Ph.D.

A major problem facing engineers today is electronics cooling. Since the 1960s the trend in electronic package design has been towards a reduction of feature size and an increase in the number of electrical components per chip. This has resulted in increased power densities and added difficulty in cooling electronic packages.

This paper presents the design of an air cooling system for one of many components on a high powered, double sided printed circuit card. The new design required optimization of an impingement apparatus which redirects parallel flow to impinge on the component. A computational fluid dynamics model was created using FLOTHERM* which shows that simple cross flow over the components is an insufficient cooling method. The model also shows that impingement cooling increases heat transfer by as much as 17%. A physical model was created to confirm the results of the computer model.

BACKGROUND

A major problem in the design of computers is cooling of the electronic components. The introduction of the integrated circuit (IC) architectures on silicon chips has resulted in a trend of increasing package densities. Since the beginning of the 1960s, this trend has led to a reduction of feature size and an increase in components per chip. This has therefore created a dramatic increase in chip power. In addition, the desire to increase computer speed has motivated engineers to place IC packages closer together. The outcome is the assembly of a great number of chips on a multilayer ceramic module, many of which are placed together on a single board. This results in a power density increase for the chip, module, and system. Therefore, advanced cooling technologies are needed. Otherwise, operating temperatures would be very large which would reduce the reliability of the computer (Incropera, 1987).

There are many methods used in the cooling of electronic components. Each method has significant advantages and disadvantages. One of the most obvious methods is the increase of air flow over the electronic modules. As simple as it may seem, this method comes with several complications. Increasing air flow usually requires a larger air moving device, resulting in less space for the electronic components or a larger electronics package. Another consequence of increasing the flow rate is that a higher pressure drop results. This pressure drop can result in increased noise in the package.

Another simple method of cooling electronics is the application of heat sinks. Heat sinks increase the surface area of the hot electrical components to increase their convective heat transfer. One problem that could arise when using this technique is that the heat sink could cause the air flow to stagnate, depending on the shape of the heat sink, and actually reduce the heat transfer from the component. Therefore, caution should be taken when choosing a heat sink to use.

A third method used often in electronics cooling is the addition of flow barriers which disrupt the flow over the components. These barriers can be designed in various shapes and sizes. They are designed to disrupt the flow over the components by creating vortices. These barriers are sometimes referred to as vortex generators. Experiments have shown that taller barriers provide greater enhancement while also causing a greater pressure drop. The enhancement percentage has been shown to be greater at lower Reynolds numbers (Schmidt, 1991).

---

* FLOTHERM is a trademark of Flomerics, Inc.

Impingement cooling is also a successful method of cooling electronics. Impingement cooling refers to heat transfer from solid surfaces using multiple fluid jets. Hollworth et al. (1989) performed an experiment measuring heat transfer and pressure drop for a system of low velocity air jets which imposed forced convection on an array of electrical components on a circuit board. Each component on the surface is cooled by a group of four air jets, and the remaining fluid is vented through drilled holes in the circuit board between components. Therefore the slightly heated fluid can be used to cool components on other boards. The final design created in this experiment, however, did not succeed in using the slightly heated air to cool other components.

This paper presents a new technique for cooling a printed circuit card. The project involves extensive computational and experimental analysis for the determination of the most effective and most feasible cooling method.

PROBLEM SPECIFICATIONS

The particular card to be cooled is shown in Figure 1, which presents a three dimensional view of a mother-daughter card. The larger bottom portion of the card is the mother card and the smaller piece attached to the top of the mother card is the daughter card. The cards are double sided, containing almost all of the same components on each side.

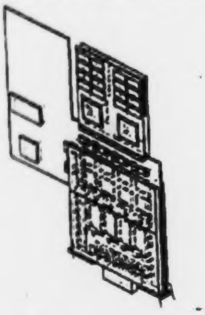

Figure 1: Mother-Daughter Card

The daughter card is approximately 137.50 mm wide and 122.05 mm tall. The main portion of the mother card, that which is directly below the daughter card, is 156.46 mm wide and 206.44 mm tall. Both cards have a thickness of approximately 2.54 mm.

There are many electrical components on each side of the card. The names of the components and their corresponding sizes and power levels can be found in Table 1. The mother-daughter cards are each 2.54 mm thick and are stacked vertically side by side approximately 34.29 mm apart, as seen in Figure 2. Channels exist between the cards through which air flows parallel to the cards.

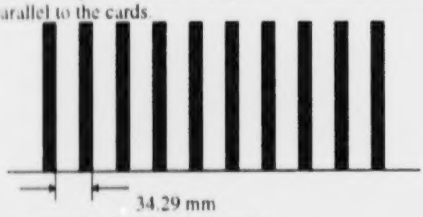

Figure 2: Card Arrangement (10 cards, 9 channels)

Air flows through 38 of these channels at a rate of 400 cubic feet per minute (cfm). Therefore the flow rate in one of these channels is 10.53 cfm. This flow rate corresponds to a flow velocity of 0.45 m/s in one channel.

PROBLEM SIMPLIFICATION

Several simplifications were made on the actual mother daughter card in order to better analyze the system. The system to be investigated would lie within one channel between two mother-daughter cards. Since the mother-daughter card has many components, it was necessary to break the card down into larger components. Figure 3 illustrates the simplified Mother-Daughter card.

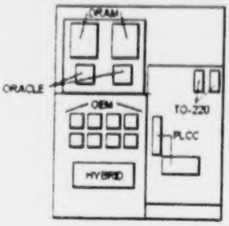

Figure 3: Two Dimensional View of Simplified Mother-Daughter Card

A summary of the changes made to the mother-daughter card can be seen in Table 1.

Table 1: Comparison of Mother-Daughter card and Simplified Version

	Actual Card					Simplified Card			
Module Name	**Power [W]**	**Thickness[mm]**	**Height [mm]**	**Width [mm]**	**Number per side**	**Power [W]**	**Height [mm]**	**Width [mm]**	**Number per side**
DRAM	2.88	16	10.87	20.64	16	23.04	55.41	45.63	2
ORACLE	1.60	2	30.76	30.76	2	1.60	30.76	30.76	2
HYBRID	9.00	4	41.38	25.81	4	36.00	41.38	103.22	1
GEM	3.00	8	22.82	22.82	8	3.00	22.82	22.82	8
PLCC*	0.80	12	14.13	14.13	12	3.20	63.03	14.13	1
PLCC**						6.40	30.43	63.03	1
TO-220*	6.00	2	9.78	16.30	2	6.00	9.78	16.30	2

*only exist on one side of card **second PLCC module on simplified card

Some preliminary calculations indicated that the HYBRID module would be one of the hottest components on the card. For further simplification of the project, the HYBRID module was chosen to be the only component for which a heat transfer enhancement apparatus would be designed.

DESIGN PROCESS

The general design chosen for testing was the insertion of an obstruction within the channel which would redirect the parallel flow perpendicular to the HYBRID module. This was done by inserting an angled plate within the channel. This angled plate contained a hole and a vertical plate which was intended to cause the parallel flow to change direction and impinge onto the component perpendicularly. Figure 4 illustrates the general geometry of this design.

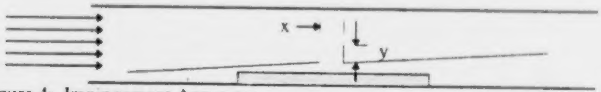

Figure 4: Impingement Apparatus

COMPUTER MODEL

FLOTHERM, by Flomerics, was used to create a computational model to simulate thermal and fluid behavior of the system. FLOTHERM is a commercial CFD (Computational Fluid Dynamics) code which uses a finite control volume technique to break up the problem into a set of non-overlapping, contiguous finite volumes. The conservation equations are solved by iterations for each of these finite volumes. Iterations are performed until the total error falls below a user defined percentage, in this case 1 %. For simulation of turbulence FLOTHERM offers both an algebraic model and a standard k-epsilon model. This project uses the standard k-epsilon turbulence model. A 2-dimensional model was created.

The computer model consists of a simple channel which contains one HYBRID module in the center. Simulations were performed using this simple model without any impingement at various flow velocities between 1 and 10 m/s. The impingement apparatus described was inserted into this simple model and an optimization process was performed to improve the heat transfer on the HYBRID module as much as possible. The optimization of the geometry of the apparatus was performed by varying the size of the opening (x) and the height of the vertical plate(y) as seen in Figure 4. Three sizes of the opening (15,20, and 25 mm) and three sizes of the vertical plate (5, 6.5, and 8 mm) were simulated to determine which geometry would give the best results.

EXPERIMENTAL MODEL

An experimental model was created for comparison with the computational results. The experimental model has the exact dimensions as the FLOTHERM model. The model is constructed of Plexiglas and the HYBRID module is made of aluminum. A foil heater was placed between the Plexiglas and the aluminum component. Three thermocouples were inserted into the component to monitor its temperature. Ambient temperatures and the outside temperature of the Plexiglas underneath the component were also measured with thermocouples. Pressure taps were drilled into the top of the channel for measurement of the pressure drop within the channel with a microtector. Experiments were performed at various power levels and flow velocities between 1 and 10 m/s.

The optimized impingement apparatus from the FLOTHERM model will be built and inserted into the physical model. Experiments will be performed similar to the previous experiments and the results will be compared to the computational results for the impingement apparatus.

RESULTS

The computational and experimental results for the simple parallel flow test agree amazingly well. Plots of Nusselt number vs. Reynolds number and Friction Factor vs. Reynolds number were created to make the comparison, as seen in Figures 5 and 6.

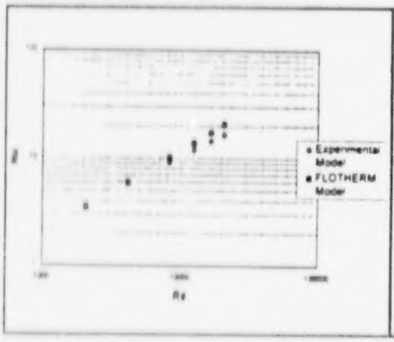

Figure 5: Effect of Velocity on Heat Transfer (Parallel Flow Case)

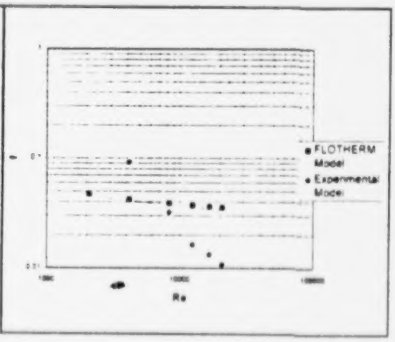

Figure 6: Effect of Flow Velocity on Friction Factor (Parallel Flow Case)

Figure 5 illustrates how FLOTHERM accurately predicted the heat transfer on the component. As flow velocity increases, the difference between the computational and experimental results increases. Figure 6 presents a great difference between the prediction of the friction factor and the actual value determined experimentally. As flow velocity increases, the friction factor decreases in the computational and experimental results. However, FLOTHERM predicts a more gradual decrease in friction factor than the experimental results indicate. This difference is most likely due to the fact that there is a great deal of error associated with the pressure drop measurements. Since the pressure drop measurements are very small in magnitude, the error is a large percentage of the readings.

Experiments have not yet been performed on the new impingement apparatus. However FLOTHERM simulations have been performed to optimize the geometry of the apparatus. The results indicate that the largest size opening (25 mm) and the largest size vertical plate (8 mm) give the best cooling results. This was determined by taking into account both heat transfer enhancement and pressure drop. A plot of the pumping power (Nusselt Number vs. the product of Reynolds Number and Friction Factor raised to the 1/3 power) of the system was used to compare the geometries with each other and the parallel flow case. Figure 7 presents a FLOTHERM drawing of the velocity vectors for the best impingement apparatus. Figure 8 shows the improvement in heat transfer when using the best apparatus.

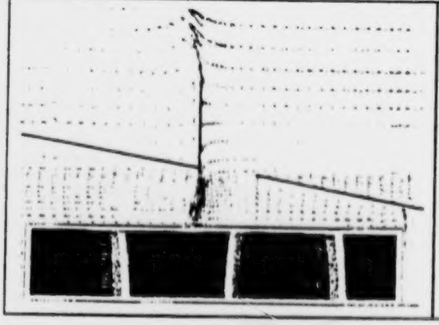

Figure 7: FLOTHERM Velocity Vectors for Best Impingement Case

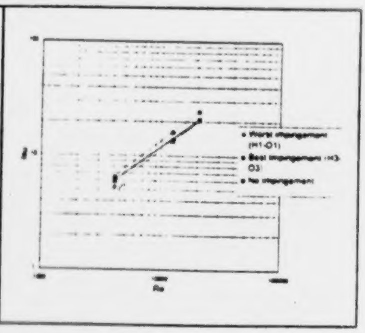

Figure 8: Effect of Flow Velocity on Heat Transfer (Computational Results Only)

Though the heat transfer is much improved using the best impingement apparatus the pressure drop is increased as well. Therefore, the simple flow data points on the plot of pumping power lie above those of the impingement cases. When determining the best and worst impingement geometries, the apparatus with the largest opening and the largest vertical plate gives rise to data which lies above that of the impingement apparatus with the small opening and small vertical plate, on the pumping power plot.

CONCLUSIONS

Impingement has been shown to improve the cooling of at least one component on the mother-daughter card. The best design of the impingement apparatus has an 8 mm high vertical plate and a 25 mm wide opening. Though the impingement apparatus results in a relatively high pressure drop, a 17% increase in heat transfer is achieved at a flow velocity of 10 m/s.

A Study of Data Issues in the GIS Environment

Jesus Acosta and Lori Alvarado

Faculty Advisor: Dr. Ann Q. Gates

ABSTRACT

Government agencies, industry and national laboratories acquire and store large amounts of geographic data collected from satellites, ground studies and other sources. The data can be used to study such things as the movement of Africanized honey bees and the placement of bridges. A Geographical Information system (GIS) is a computer-based system that provides the means to manage, manipulate, and analyze geographically referenced information, *i.e.*, data identified according to its location. Numerous off-the-shelf computer software packages exist that accomplish some or all of these functionalities. In the GIS environment, it is necessary to write software programs that interact with existing or off-the shelf software. A major issue deals with the amount, storage and format of data and its communication between programs. This paper discusses these issues and reports some preliminary findings of a fields study that we are conducting within the GIS community that may exist in writing cooperating programs.

INTRODUCTION

Government agencies, industry, and national laboratories acquire and store large amounts of geographic data collected from ground studies and other sources. The data can be used to study topics such as the movement of Africanized honey bees, land usage, and the placement of bridges. A Geographical Information System (GIS) is a computer-based system that provides the means to manage, manipulate, and analyze geographically referenced information, *i.e.*, data identified according to its location. Numerous off-the-shelf (OTS) computer software packages exist that accomplish some or all of these functionalities. In the GIS environment, it is necessary to write software programs that interact with existing or OTS software. A major issue deals with the amount, storage and format of data, and its communication between programs. This paper discusses these issues and a pilot field study being developed. The objective of the study, targeted for GIS users and developers, is to identify the issues that exist when writing cooperating programs.

The paper presents a background on GIS in section 2. Section 3 discusses the issues that are present when developing a GIS—the focus of the survey. Section 4 describes a survey instrument that will be used to determine the problems that users and developers encounter in using or developing a GIS. The last section presents a summary and discusses the future research effort.

BACKGROUND

GIS technology can be used for scientific investigations, resource management, and development planning. The types of analysis that this system must provide are measurement, mapping, monitoring, and modeling usually called the four M's of a GIS [Star 1995]. *Measurement* is concerned with storing data with various environmental parameters. A GIS must be able to retrieve old data and collect new data both efficiently and accurately.

The information may be combined with data from different sources to provide data about a region. A concern, then, is the ability to form comparisons on separate types of data. The feature of GIS that deals with integrating different types of data is referred to as *mapping*. For example, a system may allow one to relate information about the amount of rainfall to an aerial photograph of a region, providing information about which areas of the region tend to dry up at certain times of the year. Mapping data from numerous data sets permits more intense studies of regions to be conducted.

A GIS should also allow a user to *monitor* changes in data over periods of time. For example, if a GIS can store data measurements taken at different points in time, a researcher can monitor changes that may occur in these areas.

Modeling allows a user to create models based on relations. For example, given an aerial photograph of a region and elevation readings taken from remote sensing, a model of a region could be produced allowing a more detailed study of the landscape.

Systems that provide the features discussed here can be created using OTS software. Software packages such as ESRI's ArcInfo, exist that provide all of the features in one package. ArcInfo is a series of six integrated software modules that provides basic GIS tools and utilities for cartographic design, query data entry and editing, data translation, polygon overlay and buffering (image processing), network analysis, and modeling. A GIS can also be constructed by combining the different software packages that provide features necessary in such a system. A database management system such as Oracle7 can be used to store, manage and query spatial or multidimensional data. Image processing software, such as PCI's ACE, provides a complete environment for producing digital maps, integrating both vector and raster information. In addition, it includes a complete cartographic editing environment. Networking software such as Novell could also be used to create a GIS.

BEST COPY AVAILABLE

ISSUES AND SURVEY FOCUS

There are a number of issues that should be considered when developing systems in the GIS domain. These issues include the storage of data sets, handling of multiple formats, precision issues, and the integrity of the data in a GIS. GIS typically handles large amounts of data that are stored in one or more databases. It is the central part of a GIS, and must be taken into account by a developer.

One characteristic that distinguishes GIS from other computer applications is that a GIS typically uses many different types of file formats, such as raster, vector, and image data. For example, if a developer wishes to use an existing OTS database to store the data, an image processing software package that provides mapping features, and a custom-built application, then determining how the multiple packages store and operate on data must be communicated to the relevant stakeholders.

Another issue that must be considered in GIS is the precision of data. Data used for geographical studies can vary greatly in precision. Because higher resolution of data requires considerably more storage and processing time, multiple data sets may be available for the same physical area with varying resolutions. A developer who plans to interface OTS software with a custom-built application must realize that the data may vary in precision. Consider, for example, a database package that uses 32-bit numbers, and an image processing tool that interfaces with a database that uses 64-bit numbers. Because of the differences in precision, there may be loss of data during computation. Providing specifications of interfaces of the software packages that include this information would alert a developer to these types of changes.

The final issue deals with the support of integrity checking. In a GIS, data integrity is critical as data is transferred from one software component to another. Invalid data input can significantly modify information used in a study.

In order to integrate multiple software packages and, possibly, custom-built software, it is necessary to understand how the various components communicate and behave. A software architecture specification helps with analysis of the connections of a system being built because it defines the system in terms of computational components and the interactions among those components. In addition, it defines the different functionalities of the components that make up the system. Through an Architectural Description Language (ADL) [Luckham 1993] [Wiederhold 1992] [Luckham et al. 1995], the behavior, connections, and constraints of a system can be defined which allows verification of system integration. Software architectures and selected specification languages are explained in greater detail in [Acosta and Alvarado 1997].

Identifying and categorizing the ADL's that are well-suited for describing software programs in the GIS domain is a central issue. It is essential that the architectural language addresses the issues related to communicating data between components in a GIS, *i.e.*, file formats, precision, integrity of data, and other relevant information. Before looking at architectural languages as a means of specifying OTS and custom-built software in the GIS domain, several questions must be answered:

1. Do organizations have a software staff to create custom-built software in order to meet their special needs?
2. Do users find that OTS software is sufficient for their applications?
3. Is it necessary to integrate OTS software in order to get the functionality needed? If so, are the packages integrated into a single system, executed as stand-alone or piped?
4. Are hybrid systems, *i.e.*, systems built from both OTS and custom-built software, being developed?
5. If the answer is *yes* to any of the last two questions, then the following questions arise:
    (a) Do file formats, precision issues and integrity of data create problems when integrating systems?
    (b) Is an architectural specification language expressive enough to capture the properties that must be communicated in the GIS environment?
    (c) What problems occur when integrating systems in the GIS world?

The intent of the survey instrument that is described next is to find answers to these questions from the GIS community.

THE SURVEY INSTRUMENT

The survey questions are divided into five major categories: user profile, hardware platforms, OTS software, custom-built software, and data descriptions. The user profile allows us to analyze the data based on the perspective of the respondent. The intention is to survey end-users as well as developers. We are also interested in separating those developers that are Computer Scientists and those that are domain experts in order to determine if the issues vary. This section also identifies the applications of the users including their field of interest.

The section on hardware platforms is used to determine if the hardware restricts the type of OTS software that can be used. In addition, it identifies portability issues. In other words, we want to identify if problems exist when information is communicated across different platforms. The methods used to store the data are also being investigated to determine if it is an issue.

Software concerns are divided into two sections: OTS software and custom-built software. The OTS software section asks the respondent to identify the packages that he or she is using and how the packages are being used (stand-alone, integrated, or piped). There are many different types of software that can be used in a GIS, such as information software, mapping tools, database software, and image processing software. Having specific information on the software will allow us to determine what kinds of software are being combined and how they are being combined. The next section determines if the applications in

BEST COPY AVAILABLE

question require custom-built software. Again, we are interested in identifying the packages that are being used and how they are being used.

The last section examines the data issues concerning file formats, data integrity, and precision. Specifically, the intention of this section is to determine whether these areas create problems or have caused problems for the GIS in question. A GIS may potentially use many different file formats and being aware of the formats is necessary to determine whether data migrates correctly between software components. Data is stored with varying degrees of precision and it is important for developers to know information pertaining to differences in precision.

Open-ended questions are included to allow the respondent to convey other issues not asked explicitly by the survey. Selected questions from the survey are given below.

Hardware

1. What hardware platforms are used with your GIS? Check all that apply.

   (a) Desktop computer

   (b) Workstation

   (c) Mainframe

   (d) Other

Software

1. Which off-the-shelf GIS packages are you using? Check all that apply.

   (a) ARC/Info

   (b) PCI

   (c) GRASS

   (d) None

   (e) Other

2. In Table 1, list 1-4 OTS packages that you use most frequently. Rate the documentation of the given features for each of the packages using the following scale:

   0 Not present
   1 Not informative
   2 Not complete
   3 Complete, but could be better
   4 Very informative

Table 1. OTS Frequently Used Packages

Package Name	*Behavior*	*Functionalities*	*Constraints*	*Interfaces*	*Data Formats*

Data

1. What type of image file formats do you use?

   (a) GIF

   (b) JPEG

   (c) EPS

   (d) Other

2. As a developer, did you encounter problems integrating software in terms of the file formats being supported?

   (a) Yes

   (b) No

3. If you answered yes above, please explain the nature of the problem.

In order for the survey to be effective, developers and users in the GIS field must provide information on a number of characteristics pertinent to a GIS. These are reflected in the categories of questions that are present in the survey tool.

The survey is being piloted at the Integrated Training Area Management (ITDS) program under the Directorate of Environment at Ft. Bliss. After analyzing the pilot-test [Fink1 1995][Fink2 1995], the survey will be refined, finalized, and distributed through the Web. The participants will be identified through contacts in the GIS community, notified by mail about the purpose of the survey, and given the address of the web sight where the survey is located. The on-line survey provides accessibility, and the ability to administer it with ease.

After the survey has been administered, organizing the data will be the next step. This involves data entry and data screening, i.e., removing data that is not consistent with the rest of the data set [Fink2 1995].

BEST COPY AVAILABLE

[Fink3 1995] Next, the results of the survey will be analyzed. This will require explaining the findings and performing numerical computations some of the data. Through analysis, we hope to determine if the existing architectural specification languages are capable of describing the packages sufficiently. Finally, we will report the results and distribute them to the participants.

SUMMARY

GIS is applicable to scientific investigations, resource management, and development planning. These systems can be created using OTS and/or custom-built software. Frequently, systems must be built that integrate the software packages, requiring knowledge about the package's interface. Defining the system's software architecture through an ADL is beneficial; however, the language that is chosen to specify these systems must be capable of capturing knowledge that may be specific to this domain of problems. In order to determine if the issues identified in this paper are indeed issues and to discover other relevant problems, a survey instrument is being developed. The survey categorizes the information being sought into four sections: user profile, hardware, software, and data. The results of this survey will be the first step in determining whether the present ADLs are expressive enough for the GIS arena.

Quick Write vs. Quick Run
Implementation Methods for Goal Definition

Kellie Alexander and Yolanda McCullough

Atlanta, Ga. 30314

Faculty Advisor

Dr. Scott Anderson

In Artificial Intelligence, planning is a process where searching is done in order to generate a sequence of actions to solve a particular problem. UCPOP is a planning system that provides this type of problem solving. When defining a problem or goal, there are different implementation methods that may be used. Each implementation method has an effect on the computational process of the planner. In this paper, an examination of the computational and notational tradeoffs was done between the following three implementation methods: (1) defining a goal using primitive predicates, (2) defining a goal using a special domain-level operator, and (3) defining a goal using higher level axioms.

INTRODUCTION

The field of artificial intelligence(AI) is based on the study of intelligent entities. Research done in this field has one primary motivation: to examine intelligent behavior so that it may be emulated and understood through the use of computers. One aspect of intelligent behavior is the ability to plan and act so as to achieve one's goals; this process is called "planning." UCPOP is a planning system that represents a planning problem with an initial, incomplete plan, which is called the partial plan. It then attempts to complete the partial plan by expanding it with new steps until a complete plan that guarantees goal achievement is constructed. In order to execute this final plan, the agent must carry out any total order that is consistent with the partial order.

The manner in which a goal is specified can affect not only the planner's execution time for generating a final solution, but it can also affect the amount of notation that the user is required to provide when defining the goal. The use of compact, convenient notation implies hiding the details--the underlying primitive actions that the plan comprises. Since the planner can only achieve primitive predicates, it is necessary to break down abstract goals into primitive ones. How does this affect the manner in which a goal is defined? It simply means that no matter how a goal is specified, the steps used to achieve the goal must be able to be broken down in terms of primitive predicates.

This paper describes the advantages and disadvantages of specifying a goal was done in terms of primitive predicates and specifying a goal in terms of derived predicates and axioms. The research domain, called Beds World, was created in order to conduct experiments on each goal defining method. In the remainder of this paper, there follows a brief description of the research domain Beds World , a discussion of the specific methods of goal definition that were implemented, and a brief conclusion of the results regarding the tradeoffs between compact notation and efficiency.

PLANNING ENVIRONMENT

brief description of beds world

The Beds World Domain is an environment that consists of situations where actions are those that relate to making a bed. This domain contains a set of items that are needed in order to make the bed. The initial location of the items is inside of a trunk until they are retrieved for putting on the bed. In order to retrieve an item from the trunk, the trunk must be open. Only one item may be removed from the trunk at once, which in turn forces the

1131

rule that only one item may be placed on the bed at once. The following provides a description of the actual items found inside the trunk:

1. a fitted sheet, which must be placed directly on the bed
2. a flat sheet, which can only be placed on top of the fitted sheet
3. a pillow, which may be placed on the flat sheet or the comforter
4. a comforter, which may be placed on the bed after or before the pillow

vocabulary

In Beds World, the objects are the bed, the trunk, and the items located inside the trunk. They are denoted by the predicate *item* in the following manner: *(item fitted)*, which simply defines the fitted sheet as an item. The operator for placing one item on top of another is *puton(X,Y)*. This is the main operator that puts items on the bed. For example, suppose *X* is the fitted sheet and *Y* is the bed. The operator *puton* places the fitted sheet on the bed as long as the fitted sheet is not in the trunk and the two items are not the same. *Takeout(X)* is the operator used for removing items from the trunk. It removes one item from the trunk as long as the trunk is open and the item is located inside the trunk. The operators *Opentrunk(trunk)* and *Closetrunk(trunk)* are used to open and close the trunk respectively. See Figure 1 for the formal description of the operators *puton* and *opentrunk*.

goals in beds world

The main goal in Beds World is to successfully make a bed. This means that all necessary materials must be placed on the bed according to their specified order. The pillow and the comforter may be placed on the bed in two different ways: (1) the pillow before the comforter or (2) the comforter before the pillow. These two alternatives provide the planner with a choice when attempting to successfully make the bed. When this situation occurs, it is referred to as disjunctive goals--there is more than one acceptable goal. The use of disjunctive goals makes the process of planning more flexible due to multiple alternatives.

```
( operator puton
        parameters (?X ?Y)
        precondition (and (not (in ?X trunk)) (not (in ?Y trunk))
                                    (neq ?X bed) (neq ?X ?Y)
                                    (neq ?X trunk) (neq ?Y trunk))
        effect (on ?X ?Y))

( operator opentrunk
        parameters (trunk)
        precondition (closed trunk)
        effect (open trunk))
```

Figure 1. Shown above are the formal descriptions of the *puton* and *opentrunk* operators. *Puton* takes two items for its parameters and requires that both items are not in the trunk, not equal to each other or the trunk, and that the item represented by *?X* is not equal to the bed. When these conditions are satisfied *?X* is then placed on *?Y*. For the *opentrunk* operator, its only parameter is the trunk which must be closed. If this is true, then the state of the trunk changes to open.

DISCUSSION OF METHODS FOR GOAL SPECIFICATION

primitive predicates

Primitive predicates are ones that are not defined in terms of other predicates. The planning agent is able to directly achieve only primitive predicates, therefore, in order for any goal to be achieved, it must be broken down in terms of primitive predicates. One may think of a primitive predicate as implicitly defined in the planning system because the

BEST COPY AVAILABLE

planning agent "knows" what it means and how to achieve it. The description of the goal using only primitive predicates is as follows:

```
goal (or (and (on fitted bed)
              (on flat fitted)
              (on comforter flat)
              (on pillow comforter))
         (and (on fitted bed)
              (on flat fitted)
              (on pillow flat)
              (on comforter pillow)))
```

In this example, *on* is a primitive predicate because it does not use any other predicate for its definition. As will be shown in the next section, primitive predicates may also be found in the effects of operators, like *puton*, and therefore can be directly achieved by the planner. In other words, the operator *puton* is a way of achieving a state of the world where the predicate *on* is true of two things.

special domain-level operator

A special domain-level operator is an operator that contains the basic steps for achieving a goal. Goals may still be defined in terms of primitive predicates, but the use of a special operator can reduce the number of primitive predicates that are needed. The programmer is now able to define a goal using a small number of primitive predicates leaving most of the detail up to the special domain-level operator. In order to achieve the goal, the planning agent must reference the special operator in order to find the specific details for the goal. To explain how goal completion works using a special domain-level operator, consider the following scenario.

A worker for a delivery service has the assignment of delivering a package to a business in St. Louis, Missouri. The worker's goal is to get the package delivered, but he or she does not know how to get to St. Louis. In order for the assignment to be completed the worker must somehow figure out where St. Louis is and how to get there; therefore, he or she uses a map to find a specific route to St. Louis and is now able to deliver the package.

In this scenario the worker is the planning agent and the goal, i.e. the primitive predicate, is "deliver a package to St. Louis, Missouri." The map represents the special domain-level operator because it provides specific directions to St. Louis. These directions represent the primitive predicates the worker, who is the planning agent, is directly able to achieve. To show the formal notation for goal specification using primitive predicates and a special domain-level operator, the goal was defined as the following: *goal (made bed)*, where *made bed* is the primitive predicate. The special domain-level operator that provided the details, which were also primitive predicates, for achieving *made bed* was defined as:

```
( operator do-goal
     :parameters (?X ?Y)
     :precondition (or (and on fitted bed) (on flat fitted)
                        (on comforter flat) (on pillow comforter))
                        (and (on fitted bed) (on flat fitted)
                        (on pillow flat) (on comforter pillow)))
     :effect (made bed)))
```

In order for the planning agent to execute the goal *made bed*, it must use the special domain-level operator *do-goal* in order to get the specific steps that result in achieving a made bed. The use of a special domain-level operator makes the job of the programmer easier by reducing the number of primitive predicates used to define a goal. However, execution time is prolonged due to the extra reference made by the planning agent to the special domain-level operator. See table 1 for the execution times for each method.

Table 1. CPU times for both primitive predicates and special domain-level operators

Method	CPU Time
primitive predicates	0.1480
special domain-level operators	0.2550

higher level axioms

Axioms define derived predicates in turns of primitive and derived predicates. Using axioms provides a notational advantage for operators. They allow an effective way to describe domains. Even though the notation is beneficial, there is also a disadvantage when using axioms. A performance penalty can result in the use of axioms. These pros and cons of axioms can be seen through the "On" versus "Above" experiment.

The "On" versus "Above" experiment displays the advantages and disadvantages of primitive and derived predicates, with *on* being primitive and *above* being derived.

The first part of the experiment consisted of 25 uses of the primitive predicate *on* specified within the goal. The goal specification using the *on* predicate was defined as the following, where M represents a mattress:

```
goal  (and(on M1 M2) (on M2 M3) (on M3 M4) (on M4 M5) (on M5 M6)
          (on M6 M7) (on M7 M8) (on M8 M9) (on M9 M10) (on M10 M11)
          (on M11 M12) (on M12 M13) (on M13 M14) (on M14 M15)
          (on M15 M16) (on M16 M17) (on M17 M18) (on M18 M19)
          (on M19 M20) (on M20 M21) (on M21 M22) (on M22 M23)
          (on M23 M24) (on M24 M25))
```

The second part of the experiment used the derived axiom *above* instead of the *on* predicate. The derived axiom *above* was defined as the following:

```
( axiom is-above
        context (or (on ?X ?Y)
                    (and (exists (on ?X ?Z) (above (?Z ?Y))))
        implies (above ?X ?Y))
```

The axiom *above* is defined using recursion. This allows one to use more compact notation, which can be seen through the goal specification using the axiom. The goal specification is as follows:

```
goal (forall(mattress ?X) (above ?X bed))
```

The notation using the axiom *above* is more concise than the 25-clause *and* notation used with the *on* predicate. The CPU time using the derived axiom is slower than the CPU time using the primitive predicate. This implies that the uses of axioms result in a performance penalty for the tradeoff of shorter notation. See Table 2 for the execution times for primitive predicates versus higher level axioms.

Table 2. CPU times for both primitive predicates and higher level axioms

Method	CPU Time
primitive predicates	0.074
higher level axioms	0.091

BEST COPY AVAILABLE

CONCLUSION

In the area of planning, goals may be defined using several different methods. Depending on which method is used to define a goal, tradeoffs between the notation needed to define the goal and the execution time for achieving the goal may occur. This paper explores the methods of defining a goal by using (1) primitive predicates to explicitly describe the goal state, (2) a special domain-level operator, and (3) higher level axioms.

When using primitive predicates to define a goal, each primitive predicate that is needed in order to achieve the goal must be directly stated. This may force the programmer to provide a large amount of notation depending on the complexity of the problem. One way to reduce the amount of notation needed is to implement a special domain-level operator. The use of such an operator will have as its effect the goal to be achieved. The use of higher level axioms also reduces the amount of notation by using quantification, which allows the programmer to omit intermediate specifications. Although the use of special domain-level operators and higher level axioms make the job of the programmer easier by reducing the amount of notation, they result in an increase in execution time because they both require extra work by the planner.

These results were tested by running three example problems on a research domain, where each problem used a different method to define the same goal. The specific methods that were tested in this research were defining a goal using primitive predicates, special domain -level operators, as with the *do-goal* operator, and derived predicates defined using axioms, as with the *above* predicate. The findings are that primitive predicates allow faster execution time, but require a great amount of notation. Special operators and derived predicates allow a better user interface since less notation is required, but they result in slower execution time.

A Study of Environments For Successful Component Reuse in System Development

Debbie Bowles

Department of Computer Science
University of North Carolina at Asheville
One University Heights
Asheville, NC 28804-3299

Faculty Advisor: Mary Lynn Manns

Object Technology (OT), a relatively new computer system development method, has been labeled a "silver bullet" due to its ability to decrease development time by facilitating the reuse of existing system components. However, in order to get developers to reuse existing components, organizations often find that they must create an environment which encourages its developers to reuse rather than rewrite. This research examines the techniques organizations use to successfully motivate their developers to do this. On-line surveys and interviews discovered how organizations build environments which encourage effective reuse. The results provide organizations with the capability to decrease system development efforts by suggesting environments in which developers are motivated to reuse existing system components.

INTRODUCTION

Object technology (OT) is a system development method which allows the encapsulation of data and processes into entities called objects. Because of this close coupling of data and processes, code and its corresponding designs and documentation can be rather easily moved from one system to another. This ability to "reuse" represents one of the biggest advantages in using the OT method.

Reuse is defined as the ability to take a predefined component in an application that is developed in one context with the foresight of "reusing" it in other applications (Karlsson, 1995). This process has the capability to improve software quality and reduce the effort required to build systems. Many claim that reuse, rather than rewrite, allows for the development of more robust and higher quality systems which later cost less to maintain.

Even with such benefits, implementing reuse is not as simple as it may appear. Motivating developers to look into the future while developing present systems is a difficult and daunting task. The notion of reuse has changed the traditional thought process of system developers, as shown in the following quotes:

> *Reuse goes against the grain of the rugged individualism some programmers regard as an inalienable right* (Goldberg, 1995)

> *It is not my code. This is part of the NIH (Not Invented Here) syndrome of making oneself indispensable to assure job security* (Tracz, 1995)

> *Developers are usually trained to analyze a problem and implement the solution. That is, they are taught to think of software development as a complete, independent process. In this approach, using existing code is not encouraged (it's called cheating). Developers often have a strong bias against using another person's work. "I can write this faster than if I try to understand their code" is a common attitude* (Kain, 1994)

Because of the difficulties in breaking old development habits, companies often find it is necessary to provide incentives which encourage their developers to reuse. As Garry Ray points out in his article "Software Reuse Not A Panacea":

> *Programmers must be rewarded for creating reusable modules. Code must be considered a tangible asset* (Ray, 1992)

In order to understand how an organization can provide incentives for its developers to implement reuse rather than rewrite, one should consider general issues in employee motivation. The goal of motivation today, is to get employees to "go the extra mile" (Dessler, 1992). To promote "the extra mile" for reuse, organizations have found the need to create an environment that encourages reuse. Researchers report that it is important for organizations to recognize that money is no longer the incentive which motivates individuals (Hanks, 1991). As Kurt Hanks points out in his book Motivating People, "Often money is a poor motivator, especially if other problems exist" (Hanks, 1991).

Therefore, organizations need to discover what the employees needs are, rather than simply using money as a motivator for encouraging a certain performance. Some nontraditional incentives can be found in increasing an employee's self-worth, professional growth, freedom, confidence, trust, job security, and participation in the planning of the organization's future (Hanks, 1991).

The effectiveness of these incentives indicate that organizations have a new kind of worker with a new kind of attitude towards work. Increasingly, employees are requesting the right to participate in decisions which affect their jobs. It is important for a manager to recognize that "the old methods and expectations of performance will increasingly fail in future job settings" (Hanks, 1991). The idea of dangling a carrot in front of employees to get them to do some sort of task is no longer effective as it once may have been. Rather than forcing them to perform, contemporary views tap the employee's motivation to do a job.

This research explores the issue of motivating system developers to reuse. It developed a profile of twenty organizations who implement reuse by collating the strategies they use. The data will be examined to find common patterns and unique solutions to the success of the transition to reuse within the object-oriented paradigm. Towards this end, the following research question is addressed:

> When implementing Object Technology (OT), what type of environment does an organization create for encouraging its developers to implement reuse?

METHODOLOGY

Through posting to approximately 15 electronic newsgroups on the Internet and e-mailing approximately 400 professional individuals involved in OT, 20 organizations responded to the survey. Each survey requested background information about the organization, strategies used to implement reuse with OT, and a rating of success with their overall reuse plan. A section was also available for additional comments. (See Appendix A) The analysis of the survey data involved searching for common patterns between organizations who implement reuse and the success of their strategies.

RESULTS

In the first set of findings, organizations were asked to rate their success with reuse on a scale of one to four. With one being "not successful" and four being "very successful", this rating was referred to as the RSR (reuse success rate). The most interesting result was the difference between the one organization which rated itself a one and the one organization which rated itself a four. (All others rated two or three.) The reuse strategies between these two organizations were compared and it was found that the organization which reported "not successful" reuse has adopted object-oriented programming only, while the organization with "very successful" reuse utilizes object-oriented analysis and design and management techniques to support the programming development process. Within these management techniques is the management of reuse, so one can see why this organization has a better success with reuse than one which considers only the programming aspects of object technology.

In the second set of findings, organizations checked and described which of the ten particular strategies they use to encourage reuse. Table 1 lists these strategies with the percentage of the twenty organizations who checked each one. The average reuse success rate (RSR) of the organizations included in each percentage appears in the third column.

TABLE 1 Strategies for reuse

	% of 20 org	avg. rsr
Managed Reuse Library	95%	2.1
Reuse Training	75%	2.3
Advertising of reuse program	65%	1.9
Separate Library group	60%	2.2
Techniques for dealing with resistance	55%	2.4
Job positions supporting reuse	50%	2.5
Collaboration environment	50%	2.0
Recognition for writing reusable components	35%	2.3
Recognition for using reusable components	20%	3.0
Reuse management center	15%	2.0

DISCUSSION

To date, information about implementing reuse has been largely anecdotal. While many reports have been written by individual organizations, this study is the first to collate and analyze the strategies.

Ten strategies were examined in this study. The use of each one was compared to an organization's rating of its success with reuse. By far, the strategy which is used the most by the twenty organizations surveyed in this study (95%) is a managed reuse library. This is a repository of software components, which include the code, corresponding design and documentation. Coming in second and third is training in the implementation of reuse (75%) and advertising which promotes the organization's reuse program (65%). The strategy which is used within the least amount of organizations (15%) is the existence of a reuse management center. This is most likely due to the large cost which must be assumed by an organization who attempts to form a center dedicated entirely to the management of reuse.

Second from the bottom, at 20%, appears the recognition for using reusable components. However, although only 4 of the twenty organizations utilize this strategy, it earned the highest average reuse success rate (3.0 on a scale of 4). Some of the ways organizations provide this recognition is through reuse goals on performance plans, and negative feedback. The next highest RSRs were earned among the organizations who have created job positions to support reuse (2.5) and those which have techniques for dealing with resistance to reuse (2.4). Among the job positions are account manager, product manager, software reuse engineer, and infrastructure and technology engineers. Although there are many different titles, the duties include mentoring of staff development personnel, enforcing reuse, and finding new candidate components. Organizations deal with resistance to reuse through training sessions and meetings where examples are shown, reuse metrics are shared, and managers and developers are educated about reuse. Keeping in mind the limited sample, one can cautiously conclude that organizations should consider the use of these three strategies with the highest average RSR when attempting to encourage their reuse program.

LIMITATIONS OF STUDY

The main limitation of this study is the small sample size of only 20 organizations. A larger sample size would have increased the significance of this study, but was not used because this was the first attempt at exploring what organizations are doing to encourage reuse.

CONCLUSION

Object technology is a system development paradigm which holds a great deal of promise, with the facilitation of component reuse from one system to another being seen as the biggest benefit. However, implementing this reuse is difficult. To date, information on how to do this has been largely anecdotal. This study examined the reuse strategies of twenty organizations in an attempt to give a first view of how reuse can be encouraged. It is the first step in helping organizations understand what strategies they may wish to consider when establishing and implementing a reuse plan with object technology.

APPENDIX A

1. For what kinds of projects is your organization using OT?
2. What OO language(s) is/are your organization using?
3. What OO methodology is your organization using?
4. a) How long has your organization been implementing reuse?
   b) How long has your organization been implementing reuse with OT?
5. Briefly explain how your organization implements reuse.
6. Check all of the following which are used to support your organization's reuse strategy
   a)_____ A separate library group which performs quality control of components
   Explain
   b)_____ Training on use of components
   Explain
   c)_____ An environment in which developers collaborate
   Explain
   d)_____Advertisement of reuse program
   Explain
   e)_____ A managed reuse library
   Explain
   f)_____ Job positions which support the implementation of reuse
   Explain
   g)_____ Techniques for dealing with resistance to reuse
   Explain
   h)_____ A well defined reuse management center
   Explain
   i)_____ The consideration of reuse when estimating the cost of a system
   Explain
   j)_____ Recognition for writing reusable components
   Explain
   k)_____ Recognition for using reusable components
   Explain
   l)_____Other Explain
   m)_____ Other Explain
   n)_____Other Explain
7. a) On a scale of 1-4, how would you rank the success for your organization's experience with reuse.
   _____ (1) not successful
   _____ (2) moderately successful
   _____ (3) on the road to being very successful
   _____ (4) very successful
   b) Explain your ranking.

Dr. Wayne Lang

ABSTRACT

Recent developments in computer hardware speed and specialization have made physical modeling of acoustic instruments a viable method for music synthesis. However, with many diverging schools of thought on the respective roles of software and hardware in the field, it has become nearly impossible to establish benchmarks for the speed or accuracy of the hardware and software components of a given model, or the usability of a given combination. The project's primary goal was to develop an abstract C++ class library that provides a simple delineation of tasks for a complete, functioning acoustic model. The model is separated into interface, representation, and synthesis layers, each representing itself through an intuitive interface. Possible solutions to producing a performance-oriented system are studied, including Fourier-synthesizing ASIC's, scaled-time software, and distributed solutions.

INTRODUCTION

One of the most influential factors upon the music created in any period is the array of instruments and musical tools available to its artists. The twentieth century has seen the advent of widespread use of electronic musical instruments, introducing all varieties of radical new sounds and possibilities to the sonic palette of modern musicians.

There are two classes of electronic instruments: those that convert acoustic events into electronic signals and, in turn, process them (as is the case with electric guitars and the like), and those that synthesize sounds, producing them "from the ground up". Electronic music synthesis is an evolving technology; its history to date can be roughly sub-divided into four functionally and commercially prominent paradigms, each representing an "era" in the development of music synthesis: (1) analog, (2) digital algorithmic, (3) sample playback, and (4) physical modeling. Take note: there are not clear chronological dividing lines between these eras, nor has the dawn of any era led the abandonment of methods and instruments from previous ones. Vintage instruments are a prize to be cherished in the music world, and hybrid instruments are a mainstay.

Analog synthesis produces sounds using basic and well-understood electronic components; the final audio is the product of a series of basic oscillatory behaviors. Production of "realistic" sound by this method is purely coincidental, as basic oscillatory waveforms, envelopes, and filters must be found that simply "happen to" agree with physical processes. Digital algorithmic synthesis (DX, as made popular by the Yamaha DX-7) represents a similar philosophy of sound construction, but in the digital realm and with much greater flexibility. The removal of unreliable analog components (many were known to behave differently as they warmed up from continuous use, causing the instrument to go out of tune) provided a more stable performance platform, and by introducing digital operations to the datastream, programmers could go beyond the simple combinational magic of analog components and use new kinds of modifiers, feedback options, and envelope control. The final audio product was still only a mathematical abstraction, but the conceptual step away from depending exclusively upon natural electrical phenomena was significant.

The next popular technique, sample playback, approaches the problems of synthesis from the opposite end. Rather than (strictly speaking) building a sound, sample playback devices use a sparse set of recordings of an instrument and interpolate to produce the performance audio stream. In terms of simulating a "real" instrument, this was a clear step forward in realism and quality. However, it came at a conceptual cost; the construction of a sound from base components was replaced by the manipulation and combination of audio snapshots. The instrument became represented as a set of samples occurring independently in time.

This brings us to the current favorite for discussion and research, physical modeling (PM). PM techniques attempt to integrate the best of the previous two paradigms: on the one hand, the model is of real behaviors of a real instrument, hopefully producing realism; at the same time, the goal is to actually construct sound from fundamental elements rather than static snapshots, allowing the model far greater realism (Roades).

PROBLEM BACKGROUND

In theory, PM is not mathematically complex. Take, as an example, the 6-string acoustic guitar. Each string is a natural resonator; if some point on the string is displaced, the string will naturally vibrate according to well-known mathematical and physical principles. The vibration's amplitude gradually decays by dispersing energy in two ways: by vibrating the air, producing radiating sound waves, and by alternately pulling and releasing its supports, forcing the front surface of the instrument to vibrate at similar frequencies. This front surface (sounding board) in turn disperses energy by radiating sound waves and vibrating other parts of the instrument (other strings, the sound cavity, etc).

All of these acoustic phenomena are wave-oriented and, by common extrapolation from Fourier's theorem, can be synthesized from a set of sine waves with discrete amplitudes, frequencies, and phase displacements, varying over time.

Starting with a simple string (see Wood for thorough discussion), displacing it at a given point and releasing it causes it to take on an initial triangular shape. This shape is described by a Fourier series, where the amplitudes of each harmonic are described by this equation:

$$a_s = \frac{2\beta l^2}{\pi^2 s^2 d(l-d)} \sin\left(\frac{s\pi d}{l}\right) \qquad (1)$$

(here a_s is the amplitude of the s^{th} harmonic (i.e. its frequency is s times that of the first), l is the string's length, d is the distance of the displacement from an endpoint, and β is the distance of the displacement. Given these initial values, and a fundamental frequency:

$$N_1 = \frac{1}{2l}\sqrt{\frac{F}{\mu}} \qquad (2)$$

Where F is the tension on the string and μ is mass per unit length, we can describe the behavior of a string plucked at time $t=0$ as follows:

$$x(t) = \sum_{s=1}^{\infty} a_s e^{-k_s t} \cos(2\pi s N_1 t + \epsilon_s) \qquad (3)$$

where $x(t)$ is displacement according to time, N_1 is the fundamental's frequency, k_s are decay constants (also available from well-known functions) and ϵ_s are phase constants (zero in this case). These equations are incrementally complicated by factors including string stiffness and loading, support yielding, and so forth.

The subsequent steps become more unwieldy as they progress; the strings are the only components that resonate naturally, and when members of the Fourier series of two individual strings are similar to each other, they produce sympathetic vibrations in accordance with the bell-shaped resonance curve. The set of strings in turn drives vibrations in the body of the guitar and the sound cavity, according to more resonance curves dependent upon the physical descriptions and characteristics of the instrument.

All told, there are simply too many phenomena at work, many of which involve a theoretically infinite set of discrete behaviors. The result is a mathematical quagmire that is simply unsolvable in anything approximating real-time; thankfully, there are at least two popular workarounds. The first is to limit the depth to which the instrument will be modeled, e.g. only representing 64 harmonics of a component or two levels of induction. The second is to represent instruments alinearly, i.e., to represent behaviors not only in terms of discrete components in time, but more (or exclusively) in terms of prior behavior: $x(t)$ is a function of $x(t_0<t)$. Which is the "correct" or "best" approach? No one can say. This is the first part of the problem: there is no "best" methodology for mathematically representing an instrument.

Whatever representation is chosen, the solution of that model at performance-time must be handled by a computer, in which that task must be divided between two components: hardware and software. All told, it is not clear whether hardware, software, or some balanced hybrid represents the "best approach" to executing a model; what's more, the answer is most likely solution-specific.

The problem addressed herein is that of providing a workable standard interface about which one should be able to map a modeling systems onto a hardware/software divide. A template is presented using sets of C++ class libraries, collectively referred to as "PMA" (Physical Model Abstraction). The goal of these libraries is to virtualize interaction between the various components of a working physical model, and provide a method for testing and benchmarking various methods and components used in combination with each other.

SYSTEM REPRESENTATION

For simplicity, the PMA specification assumes that the model will be able to represent its behaviors in terms of sine-wave oscillators. This is not so restrictive as it may appear; a well-parameterized additive sine-wave synthesizer (ASWS) can handle fixed offsets, phase jumps, and other magic that non-linear models may need. The particular PMA library presented also only represents plucked-string instruments (6-string guitar, ukelele, etc); limited groundwork exists for driven-resonator instruments (horns, bowed strings), and these cases are beyond the scope of this project.

A PMA-centered system is decomposed into three parts: the user interface, the physical model itself, and the ASWS engine. The interaction between these layers is defined by the classes composing each layer, which can be arbitrarily implemented in hardware or software.

The PMA library is composed almost entirely of C++ classes; the object-oriented structure was excellent for providing a skeletal functionality and interface, while allowing the normal system-level control of C. A complete specification and source code will soon be freely available on the internet at the PMA web site (Bradley).

WORKING MODELS

No protocol or standard is worthy of substantial consideration until it is shown functional through an at least marginally working implementation. Discussed below are the implementations of a first-principles physical model and two approaches to the ASWS engine.

Demonstration Model: First-Principles Modeling

The excitation of the fully-connected guitar instrument involves the potential total interaction of all components (strings and driven resonators); thus, any change in the system has the potential to propagate in a $O(n^2)$ operation. While escaping the n^2 order is almost impossible for an elementary first-principles model (although conceivable using high-order calculus to represent systematic couplings), a great many optimizations can be performed to produce net reductions in performance and pre-performance calculations.

To reduce storage requirements and list-parsing cost, each string object owns a set of queues representing the oscillators that string is allowed to influence, and how that influence relates to its own particular harmonics. Each of these queues should be pre-created, a classic memory-for-performance trade. The number of queues appears to be quite substantial: each string requires a unique hard-resonator queue for each of its own frets, and each string to string couplings can (through a trick of physics) be characterized by a one-dimensional array, the difference of their frettings (ΔFret).

All told, the final set of queues is representable by these two multidimensional arrays:

```
ResonatorQueue[SourceString][Fret]
StringQueue[SourceString][TargetString][ΔFret]
```

Thus, a potentially massive (and sparse) set of interactions is stored in two easily-accessible arrays of easily-parsed queues.

Demonstration Engine: CPU-Loading

A software-oriented ASWS is not (theoretically) complicated. The state of an individual oscillator is represented by amplitude, phase, ΔPhase (representing frequency), and constant of natural decay. The first two are updated at (theoretically) discrete time intervals, the last as control parameters.

Performance depends greatly upon the choice of internal data formats and operations and the host's ability to perform those operations quickly; however, current common-language compilers (outside of a few academic experiments) cannot handle the selection of data formats to optimize for a given execution environment.

Consider a reasonably complicated model, consisting of 512 oscillators, all of which must be updated and polled at 44.1kHz: over 22 million oscillator updates (66 million values) per second. With a 500MIPS processor (with register-speed memory), that leaves 7 instructions per update, almost impossible with an abstract language or a single-CPU system.

Demonstration Engine: Application-Specific Integrated Circuit

The concept of using an application-specific integrated circuit (ASIC) to perform additive sine-wave synthesis (ASWS) is fairly popular (Houghton 26), but faces problems analogous to those of software-oriented solutions: a highly complicated circuit cannot be clocked any faster than data can propagate through its components, thus restricting how many oscillators can simulated in real-time by a monolithic digital oscillator set. A viable solution is pipelining, breaking an operation into simple sequential components which can be performed serially on an incoming stream of data. The result is a circuit with "stages" that can be clocked quickly, interconnected to allow multiple data to be "in process" at all times.

A high-level model of an ASWS-ASIC was designed with this in mind; it is referred to as "PMA-Impl" and is specified at the PMA web site (Bradley). Design complications such as parallel memory access, data representation, and

Consider the example given for the CPU-Loaded case above, of a fairly involved model with 512 oscillators operating at 44.1kHz. If the proper data input mechanism is provided, the system will do all calculations in real-time with an internal clock of just over 22.5MHz, and requires (if output is direct-to-line instead of back-to-software) zero software overhead.

What's more, the system scales linearly: 1024 oscillators can be handled by clocking the system at 45MHz, and multiple chips can be run in parallel to increase the number of oscillators proportionally. The only constraint is control software speed.

A virtual model of PMA-Impl was constructed using a simple C++ component library. This shows, with clock-level resolution, how the ASIC would perform in real-time. The system is generally sound, although currently suffers a few border-condition oddities.

DISCUSSION: FUTURE IMPLEMENTATIONS

Without the restraint of real-time performance, a great many possibilities are opened up for the modeling layer. There are many theories and approaches that are, for a variety of reasons, simply not practical or performable in real-time. Also of interest is the ability to distribute modeling computations over a loosely-coupled network. Because all control events can be pre-known to the model, the tight coupling needed to do distributed modeling at performance-time is not an issue; this can produce substantial processing-time speedups, potentially (if the distribution process and operations scale well and the system is large enough) allowing computation time to drop below the actual duration of the product audio. This kind of performance would not qualify the model as real-time, however, as it depends on pre-knowledge of performance data, which is by definition unavailable to a real-time model.

The utility of real-time solutions in a commercial market is far more apparent, and it also poses interesting challenges for popular fields of computer science. Perhaps among the most promising avenues to pursue in developing real-time physical models is the use of multi-processing hardware and operating systems. Generally speaking, implementing a real-time physical model in a loosely coupled network is impractical if not impossible. Bandwidth restrictions over serial links and latency and predictability issues for ethernet communications may prevent the kind of microsecond-scale timing necessary to simulate an acoustic system. However, tightly-coupled computers show promise for making real-time software-based synthesis a practical reality; of particular interest is the special case of shared-memory or symmetric multiprocessing (SMP).

Consider, for example, an SMP system with n processors (where n>1), under the complete control of the model system (i.e., no preemptive scheduling and minimal OS processor usage). The first processor is set aside to handle the user interface (generally a minimal task) and the modeling mathematics, and the n-1 remaining processors are all dedicated to emulating the oscillators. The high-end single-processor restriction discussed above is easily overcome if proper memory architecture and safeguards are provided. Porting of a generalized operating system (e.g., a UNIX variant) to such a system would be no small task because of the radical performance restraints on memory layout.

CONCLUSIONS

If physical modeling is to be the next generation of commercial synthesis, then development work must continue in designing software and hardware that will enable it, and standard frameworks around which all varieties of technologies and techniques can be tested would certainly accelerate such work. Approaches taken in this project, including the PMA-Impl ASWS-ASIC, show that complex performance-oriented physical modeling may be realistically doable in the very near future.

What's more, these frameworks provide a vehicle for better understanding the roles and requirements upon all the components of a PM system: not just the model and synthesis systems themselves, but their complete operating environment, including available hardware, operating system mechanisms and policies, and target functionality. Indeed, the goal of this project was not so much to answer the great questions facing this developing field, but to facilitate new ways to discover, understand, and tackle them.

A Parallel Solution of a Second Order Elliptic System

Andre Da Breau and Lwanga M. Phillip

The Centre for Research in High Performance Computing (CRHPC)
Morehouse College, 830 Westview Dr., Atlanta, Georgia 30314

Faculty Advisor:
Okon H. Akpan, Ph.D.

This research was focused on the use of a massively parallel processor (MPP) for efficient solution of a second order elliptic partial differential equation with dirichlet boundary conditions on a regular domain. The MPP used was the NASA MasPar MP-1, a SIMD class processor remotely accessed at Morehouse College. The problem domain was discretized with both the 5-star and the 9-star centered difference stencils, and the equilibrium values of the dependent variable computed in parallel at the grid points. The equivalent pentadiagonal system, represented as 5 nonzero vectors, was also solved using the unconditioned conjugate gradient method whose results were used as a testbed for the parallel solutions.

THE PHYSICAL PROBLEM

The problem chosen for the study was a second order elliptic partial differential equation given as

$$\nabla^2 u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = f(x,y) = -2, \quad 0 < x < 1, \; 0 < y < 1. \tag{1}$$

with boundary conditions

$$\begin{aligned} u(0,y) &= 0, \quad u(1,y) = sinh(\pi)sin\pi y, & 0 \le y \le 1, \\ u(x,0) &= u(x,1) = x(1-x), & 0 \le x \le 1 \end{aligned} \tag{2}$$

The analytical solution of eqn(1), given the domain and the boundary conditions, was found to be

$$u(x,y) = sinh(\pi x)sin(\pi y) + x(1-x). \tag{3}$$

The elliptic equation was a second order Poisson equation which often arises naturally as a model of a number of time-independent physical systems such as the steady state distribution of heat (in which case u is temperature), or the steady state diffusion problem (in that case u is concentration), or the steady state distribution of potential of any quantity where the rate of flow is proportional to the gradient, $\nabla^2 u$. In our study, the Poisson equation was regarded in the context of steady state distribution of heat on a unit square domain, $(0,1) \times (0,1)$.

MATHEMATICAL TOOLS

Because of the regularity of the domain, the finite difference quotients were used for domain discretization. This technique and others not utilized in this study are described in detail in any good numerical texts such as (Burden, 1988) and (Gerald, 1996). The problem domain discretization was carried out by partitioning the domain, $(0,1) \times (0,1)$, in the x- and y-directions using the same width size, h, into n subdivisions in each direction. The result was an $N = (n-1) \times (n-1)$ grid-work whose grid points were ordered row-wise or in what is known as natural ordering. Other ordering schemes exist, and a few of the commonly used ones are the Red-Black, and the Cuthill-McKee orderings (Baucom, 1988).

Next, the second partial derivatives of eqn(1) were replaced by the second centered finite difference quotients to obtain the system approximation

$$\nabla^2 u_{ij} \approx \frac{u_{i-1} + u_{i+1} + u_{j-1} + u_{j+1} - 4u_{ij}}{h^2} = -2. \tag{4}$$

with boundary conditions

$$\begin{aligned} u(0,jh) &= 0, \quad u(1,jh) = sinh(\pi)sin\pi jh, & 0 \le jh \le 1, \\ u(ih,0) &= u(h,1) = ih(1-ih), & 0 \le ih \le 1 \end{aligned} \tag{5}$$

BEST COPY AVAILABLE

Note that eqn(4) is the approximation of eqn(1), and that every grid point (x,y) was replaced by (ih, jh). Eqn(4) could be represented symbolically as

$$\nabla^2 u_{ij} = \frac{1}{h^2}\left\{\begin{array}{ccc} & 1 & \\ 1 & -4 & 1 \\ & 1 & \end{array}\right\} u_{ij} + 2 = 0. \tag{6}$$

the representation often known as the *five-star* difference template, for an obvious reason. Following the similar arguments, a *nine-star* finite difference template,

$$\nabla^2 u_{ij} = \frac{1}{h^2}\left\{\begin{array}{ccc} 1 & 4 & 1 \\ 4 & -20 & 4 \\ 1 & 4 & 1 \end{array}\right\} u_{ij} + 2 = 0. \tag{7}$$

was also obtained for the system approximation.

Finally, the above templates were separately applied on each of the interior grid points, and the result was an $N \times N$ linear system of equations, $Au = k$, where the vector k resulted from the boundary conditions and the forcing function, $f(ih, jh)$. The linear system had the following properties. The matrix A was

- a symmetrically banded structure with a semibandwidth of β, (recall that β = n-1, and that "symmetric" implies that $\mathbf{A} = \mathbf{A^T}$).
- diagonally dominant. That is, $|\, a_{ii} \,| > |\, \sum_{k=1, k\neq i}^{N} a_{ki} \,| \quad for\ i = 1, 2, \cdots, N$.
- positive definite. That is, $\forall \mathbf{x} \neq \mathbf{0}, \mathbf{x}^T\mathbf{A}\mathbf{x} > 0$. Hence the system was guaranteed to have nonzero eigenvalues, and, consequently, to be **nonsingular** (that is, have unique solutions).
- highly sparse. That is, most of its elements were zeros. In fact, for the linear system of dimension N = 129 (that is, when $h \approx 0.0078$), 16,641 equations, each with at most five variables, resulted. The matrix **A** then had over 276 million entries of which about 83,000 ($\approx$ 0.03%) were nonzero. Thus, in double precision arithmetic, which was the precision for computations in this work, over 2,000 MBytes of memory space would be needed to hold just the zero elements! In this study, we used data structures to hold only the nonzero elements and thus to enormously conserve the memory space utilized.

COMPUTATIONAL TOOLS

The parallel processor used for all of the computations in this study was the NASA MasPar MP-1 manufactured by the MasPar Computer Corporation. MP-1 is a 16,384-PE, *fine-grained, massively parallel, SIMD-class* processor with *distributed memory*. This processor is said to have a theoretical performance peak of 550 Mflops (double-precision) and 1,200 Mflops (single-precision) (Dongara, 1994). The MP-1 (see figure 1) consists of two major components, the Front End (FE) which is a DECstation 5000 running the ULTRIX

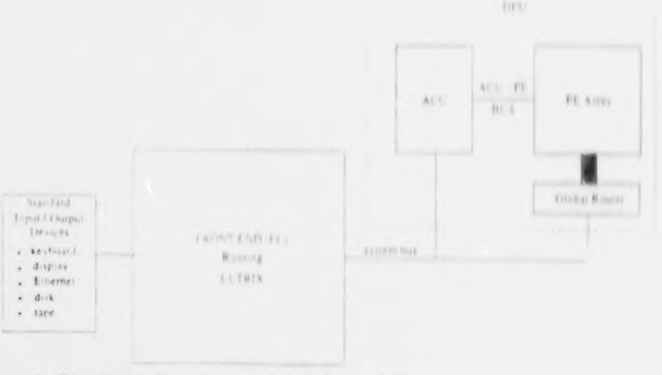

Figure 1. The Major Components of the Maspar MP-1

BEST COPY AVAILABLE

and the Data Parallel Unit (DPU) which consists of a control processor known as the Array Control Unit (ACU) and an array of processing elements called the PE Array. The ACU is a register-based load/store processor with its own registers (32 32-bit registers), and a 128Kbyte memory. Each PE is a 1.8 MIPS, RISC-based, load/store processor with its own 42 32-bit registers and a 16KByte RAM. PEs are arranged in a two-dimensional array of 1K, 2K, 4K, or 16K PEs. Our MP-1 has 16K (or 16,384) PEs. ACU is the control processor which performs instruction decode and broadcast to the active PEs in the PE array. Thus the DPU is the only MP-1 component responsible for parallel computation.

The MP-1 softwares fall into two main categories: the Maspar Programming Environment, a very rich source of programming and programming-aiding tools, and programming languages. Presently, MP-1 supports two programming languages: the MasPar FORTRAN (MPF) which is based on FORTRAN 77 and FORTRAN 90, and the ANSI-based MasPar Programming language (MPL), the language of choice in this study. MPF is quite high level, and programming in MPF does not call for a detailed understanding of the underlying hardware. Programming in MPL, on the other hand, calls for a reasonable mastery of the underlying hardware features of the MP-1.

In MPL, a variable belongs to one of the two storage classes: *plural* or *singular*. Any variable (elementary or structured) declared with the key word "plural" is allocated identically on each PE's local memory, whereas any variable declared without the *plural* key word is a *singular* variable which is allocated on the ACU's memory.

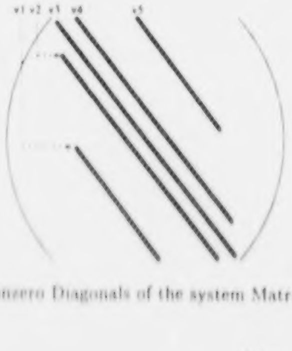
NUMERICAL SOLUTION OF THE PROBLEM

In the parallel computation, the gridwork was regarded as the MP-1 PE array, and each interior grid point as a PE. The simulation used the algorithm in figure 2 below:

```
STEP 1: Choose integer, m, and determine the corresponding grid width, h (see §2.1).
STEP 2: Partition the domain (0,1) × (0,1) to obtain the grid work. Each grid
          point is a PE and the system dimension, N, is the number of active PEs.
STEP 3: Determine the boundary values as elementary plural variables.
STEP 4: Declare 3 plural variables, old_u, new_u, temp_u and a singular parameter, tol.
                    plural double old_u, new_u, temp_u;
                    double tol;
STEP 5: Initialize old_u, and tol. /* tolerance = 10^-9 */
STEP 6: For each active PE DO
        Step 6.1: Simulate eqn(6) (or eqn(7)) getting old_u from neighboring PEs.
        Step 6.2: Update temp_u with old_u, and old_u with new_u.
STEP 7: UNTIL |new_u - temp_u| ≤ tol.
```

Figure 2: Algorithm for Parallel Program

The sequential solution method chosen for solving the linear system was the unconditioned *conjugate gradient* method. Because the system was highly sparse, the nonzero elements of the matrix were held in five vectors v1,···,v5 whose structures are given in figure 3, while the sequential solution algorithm is given in figure 4.



$$v1 = (\overbrace{0, \cdots, 0}^{\beta}, 1, \cdots, 1)$$

$$v2 = (\overbrace{0, \cdots, 1}^{\beta}, 1, \cdots, 1)$$

$$v3 = (-4, -4, \cdots, -4)$$

$$v4 = (1, \cdots, 1\ \overbrace{1, \cdots, 0}^{\beta})$$

$$v5 = (1, \cdots, 1\ \overbrace{0, \cdots, 0}^{\beta})$$

Figure 3: Nonzero Diagonals of the system Matrix and the Vectors to hold them

```
STEP 1: Declare the vectors v1,···, v5, fe_v:

 double v1[N],v2[N],v3[N],v4[N],v5[N];

STEP 2: Initialize v1,···,v5 (see figure 4)
STEP 3: Pass the vectors and N to DPU
 callRequest(Cgrad, 24, v1, v2, v3, v4, v5, N);
STEP 4: Get solution vector, fe_v, from DPU:
 copyIn(fe_v, dpu_v, sizeof(double));

STEP 5: Print out the solution vector.
```

(A)

```
STEP 1: Declare the vexes vv1,···,
  vv5, dpu_v:
   plural double * vv1, *vv2, *vv3, *vv4,
  vv5, *dpu_v;
STEP 2: Obtain memory slices for vexes:
  nd = N >> lnproc + 1;
  STEP 3: Allocate the vexes
   vv1 = gestord(nd);
   vv2 = gestord(nd);
   vv3 = gestord(nd);
   vv4 = gestord(nd);
   vv5 = gestord(nd);
  dpu_v = gestord(nd);
STEP 4: Represent the vexes in virtual
  memory space
STEP 5: Call the function, Cgrad with
  the vexes.
STEP 6: Copy back to FE the solution
  vector, dpu_v:
  blockOut(dpu_v, v1, 0, 0, 1, N,
  sizeof(double));
```

12	5.99200	6.10386	6.10386	5.99813	0.11186	0.11186	0.00613
16	3.76437	3.83351	3.83351	3.78082	0.06914	0.06914	0.01645

RESULTS

Both the parallel and sequential algorithms were implemented with several different grid widths, h, for the numerical solution of the physical system whose model is given in eqn(1). The analytical or exact solution of the same problem, was also obtained by solving eqn(3). Table 1 shows one set of results in the case where h value is 0.2.

At large grid widths, there was no significant difference in the accuracy of the 5-star and the conjugate gradient solutions, but, as the grid widths became small, the 5-star solution became increasingly more accurate than the conjugate gradient. Thus, when $h = 0.2$, the average absolute error of both the 5-star and the conjugate gradient solution was the same, 0.07096; at $h = 0.1$, the average error of the 5-star solution was 0.01817 compared to 0.01830 of the conjugate gradients; at the smaller values of h, the accuracy of the 5-star's solution in comparison to that of the conjugate gradient was even more pronounced. The 9-star solutions were more accurate than both the 5-star and the conjugate gradient solutions at all grid widths, and were even more so for smaller values of h. For example, at $h = 0.2$, the average absolute error of the 9-star solution was 0.00514 compared to the 5-star's 0.07096, and at $h = 0.05$, the 9-star's average error was 0.00039 compared to the 5-star's 0.00456.

The speedups were determined with respect to the CPU time from the execution of the conjugate gradient program and also from the average time n for execution of the parallel counterparts, the 5-star and 9-star programs. Such comparison was deemed fair since all programs ran on the DPU except, of course, the preprocessing code portion of the conjugate gradient which ran on the Front End. At the values of h ranging from 0.2 to 0.05 ($N = 16$ to $N = 361$), the average CPU time to execute the conjugate program was 0.8424, while those of the 5-star and 9-star programs were respectively 0.6606 and 0.5353. This gave the average speedup of 1.27 for the 5-star solution, and 1.57 for the 9-star solution.

Finally, at all values of h, the 5-star solutions had a better load balance than the 9-star solutions, the difference was greater as h became smaller. Thus, at $h = 0.2$, the 5-star showed a load balance of 91% compared to the 9-star's 89%; at $h = 0.05$, the 5-star's load balance was 90% while the 9-star's was only 77%.

CONCLUSION

From the results, we concluded that the 5-star solution of the Poisson equation given in eqn(1) is more practical than the conjugate gradient solution method. This is because the 5-star solution is not only more accurate than the conjugate gradient solution especially in large system dimensions, but it is also much simpler to understand and code than the conjugate gradient method. Representing the system with *vexes* for nonzero elements, instead of a *mat* for the original matrix, significantly complicated coding of the conjugate gradient program. On the other hand, the dominant portion of the 5-star program involved 4-nearest neighbor communication which was easily realized with the *xnet* constructs. Because the 9-star solution was more accurate than the solution of any other method in all system dimension, then, if accuracy is premium, the 9-star solution approach should be preferred to other approaches only at small h values since the 9-star shows significant load imbalance at small h values. The two parallel approaches, the 5-star and 9-star, however, were deficient in speedup, but this deficiency was somewhat offset by the simplicity of their codes.

ACKNOWLEDGEMENT

We wish to thank Dr. John Hopps, the Provost and Senior Vice president for the Academic Affairs of Morehouse College, for his indefatigable energy and support which proved to be indispensable for the successful completion of this project, and, better yet, for his promise for more future support. We are also grateful to Dr. John Dorband of the NASA HPCC, GSFC, whose mentorship was a guiding light illuminating many a tortuous path through this project. Finally, we thank the National Science Foundation and the National Aeronautics and Space Administration for providing both the seed funding and equipment for the Morehouse HPC project.

The solution of finite element and finite difference problems is important for a variety of physical problems. A recursive substructuring method is presented that allows for a lower processor communication overhead and therefore more efficient parallelization of such problems. To illustrate the method, an example finite difference solution is developed and the advantages of the method are discussed.

INTRODUCTION

Numerical solutions to physical problems and differential equations often involve utilizing finite element and finite difference methods and result in the creation and solution of matrix equations that feature large, sparse matrices. In particular, the parallel version of a global atmospheric circulation model developed by *Porter et al.* [1996], an extension of the model developed by *Chan et al.* [1994], requires the solution of such large matrix equations. The sheer size of these and other matrix systems means that any serial solution technique would be slow. Thus, such problems are often tackled using multiple parallel processors, requiring a reformulation of the problem for a parallel method of solution. The classic parallel approach to such problems involves an LU factorization of the matrix equation accomplished through a round robin distribution of the matrix equation over the processors involved [*Fox et al.*, 1988]. However, this method is limited in that it requires the entire matrix to be passed among the processors, and the back-substitution step is virtually performed in serial, meaning that the communication overhead for this method is high. Because of the high communication for this approach, *Porter et al.* explored a different parallelization made possible by large scale granularity of the block diagonal structure for a spectral formulation of a global atmospheric model and found significant speedups. However, slow communication speeds for the distributed network environment prevented parallel speedups beyond a factor of five. The recursive substructuring method presented in this paper was developed to improve upon these communication drawbacks and those of the round robin distribution method as well, and it does so by developing a new parallel formulation of the problem. This paper presents an overview of the recursive substructuring method, a demonstrative example of the method applied to a simple differential equation, and a brief analysis of the advantages offered by the method.

OVERVIEW OF THE METHOD

The recursive substructuring method involves three key concepts that grant it its parallel advantages -- the hierarchical structure, the elimination step, and the resolve step. The first is a different logical approach for decomposing the problem, and the second two exploit mathematical relationships that can take advantage of that hierarchy. The basic mathematics simply utilizes established techniques for matrix formulation of systems of equations such as the finite element and finite difference method [*Press et al.*, 1992].

The hierarchical structure of a given problem begins by discretizing the problem into n similar elements. As might be expected, the larger n is for a fixed domain, the finer the solutions generated but the greater the amount of computation involved. The hierarchy is a collection of bottom-, middle-, and top-level processors with varying responsibilities. (See Fig. 1) Each bottom-level processor is responsible for assembling basic elements and condensing them into a single superelement. Then, bottom-level processors send their superelements to the middle-level processor immediately above them in the hierarchy. Middle-level processors, like the processors below them, assemble and condense their elements into a single superelement to be passed above. A single top-level processor collects the resultant superelements, assembles and condenses them into a single element that represents the final reduced problem. It is here that boundary conditions are used to solve the reduced system. This solution is passed down the hierarchy, a resolve for internal elements occurs at each level, and eventually the bottom-level processors generate solution vectors for their internal elements. (See Fig. 1) Taken together, these resultant basic elemental solutions describe the entire solution vector for the problem.

The method depends on the ability to assemble elements hierarchically and recursively condense them into a single element. The assembly and condensation is an extension of the static condensation method often used in finite element analysis. In a typical problem formulation, each elemental component of the problem generates a composite matrix equation of the form

$$KX = F \tag{1}$$

where X is the solution vector we wish to solve for, and K and F are known. This composite matrix is termed an elemental matrix. Each elemental matrix has a similar form, and, through some operator that depends on the problem domain, these elemental matrix equations can be assembled into a larger matrix equation that has the same form as (1). This assembled matrix equation is remapped so that all information about the exterior of the region covered by the local elements is sent to the rightmost columns and bottom-most rows of the respective matrices. When this is done, the assembled matrix equation takes the form

$$\left[\begin{array}{c|c} K_{II} & K_{IE} \\ \hline K_{EI} & K_{EE} \end{array}\right]\left[\begin{array}{c} X_I \\ \hline X_E \end{array}\right] = \left[\begin{array}{c} F_I \\ \hline F_E \end{array}\right] \tag{2}$$

where the subscripts $_I$ and $_E$ refer to the interior and exterior of the region. Note that (2) gives us the system of matrix equations

$$\begin{aligned} K_{II} X_I + K_{IE} X_E &= F_I \\ K_{EI} X_I + K_{EE} X_E &= F_E \end{aligned} \tag{3}$$

The first equation can be solved for X_I

$$X_I = K_{II}^{-1}(F_I - K_{IE} X_E). \tag{4}$$

Substituting that into the second equation

$$K_{EI} K_{II}^{-1}(F_I - K_{IE} X_E) + K_{EE} X_E = F_E \tag{5}$$

and rearranging terms, one obtains

$$K' X_E = F_E' \tag{6}$$

where

$$K' = K_{EE} - K_{EI} K_{II}^{-1} K_{IE} \qquad \text{and} \qquad F_E' = F_E - K_{EI} K_{II}^{-1} F_I$$

Note that (6) has the same form as (1) and all interior variables have been eliminated. Given proper boundary conditions, we can solve (6) for X_E, the external part of our desired solution vector.

Once all elements have been assembled and eliminated and passed up the hierarchy, the resolve process can begin. The top-level processor receives its boundary conditions -- which equate to the final X_E in the top-level elimination process. When X_E is known, (4) is used to find X_I for the top-level maximal element. Then the current level's full solution vector is known. This solution vector is then decomposed into its local elemental pieces, and these elemental solution vectors are sent down the hierarchy for further solutions. Eventually the bottom-level processors receive their X_E from above, and they resolve for the basic elemental solution vectors, and the full solution is generated.

EXTENDED EXAMPLE

In the following, a simple example will be used to illustrate an application of recursive substructuring to the solution of a differential equation. Let us consider the second order differential equation

$$\frac{dy}{dx} + \frac{d^2y}{dx^2} = x \tag{7}$$

on the interval [0,2] with initial conditions y(0) = y(2) = 1. Analytic solution of this problem yields

$$y(x) = \frac{1}{2}x^2 - x + 1 \tag{8}$$

The numerical solution found through recursive substructuring should accurately approximate this analytic result.

The first step is to partition the solution interval [0,2] into 8 subintervals of equal length at $x_0 = 0$, $x_1 = 0.25$, $x_2 = 0.5$, ..., $x_7 = 1.75$, $x_8 = 2$. Solutions $y_0, y_1, \ldots, y_8$ will be generated corresponding to each of the x_i. Note that from the initial conditions, $y_0 = y_8 = 1$.

Next, applying the finite difference method to the differential equation (7) yields

BEST COPY AVAILABLE

$$\left(\frac{1}{(\Delta x)^2}-\frac{1}{2\Delta x}\right)y_{n-1}+\left(\frac{-2}{(\Delta x)^2}\right)y_N+\left(\frac{1}{(\Delta x)^2}+\frac{1}{2\Delta x}\right)y_{n+1}=x_n \tag{9}$$

Note that since Dx=0.25 for this sample problem, (9) simplifies to

$$14y_{n-1}-32y_n+18y_{n+1}=x_n \tag{10}$$

This approximate solution for y is valid for each of the interior points in the partition, namely x_1 through x_7. Thus, 7 "elements," in our terminology, are generated -- 7 coupled equations with solution vector $<y_0, y_1, \ldots, y_8>$.

Using traditional finite difference methods, the system of 7 equations generated by (10) for n=1,...,7 would be translated into matrix form and solved simultaneously. In parallel, this would typically entail using a round robin distribution method to achieve load balancing. However, the recursive substructuring method will be applied at this point in order to clarify the workings of that method.

The first step in the recursive substructuring method is to place the "elements" in a processor hierarchy. Four processors will be used -- three bottom-level processors and one top-level master processor. The bottom-level processors are chosen to illustrate the various couplings possible between processors. Each bottom-level processor will be responsible for a given subinterval. Because each element is coupled to its neighbors, there will be some overlap among the y_i contained on each bottom-level processor. However, this overlap is minimal, in that only y_i on the borders of the processor subintervals will be shared among processors. The small-scale example here does not reflect this, but ordinarily, a given processor is responsible for a number of y_i, with only a few of those shared with another processor.

Each bottom-level processor will condense its three elements into a single superelement that represents the subinterval from which it was formed. In the following, envision processors P_{21}, P_{22}, and P_{23} as bottom-level processors in Fig. 1. All three superelements, one from each bottom-level processor, will be sent to the fourth top-level processor P_{11} where a similar process will condense those superelements into one element for the entire interval [0,2]. The processor responsibilities for the problem at hand based on the elements L_1 through L_7 as seen in Figure 2 will be as follows:

Processor One (P_{21}) : handles the interval $[x_0, x_4] = [0, 1]$, has responsibility for elements L_1, L_2 and L_3, and it produces superelement S_{21}.

Processor Two (P_{22}) : handles the interval $[x_2, x_6] = [0.5, 1.5]$, has responsibility for elements L_3, L_4, and L_5, and it produces superelement S_{22}.

Processor Three (P_{23}) : handles the interval $[x_4, x_8] = [1, 2]$, has responsibility for elements L_5, L_6, and L_7, and it produces superelement S_{23}.

Processor Four (P_4) : handles the entire interval $[x_0, x_8] = [0, 2]$, accepts superelements S_{21}, S_{22}, and S_{23} and solve the reduced system.

Assembling P_{21}'s equations and rewriting to isolate the "exterior" y_i, we obtain

$$\left[\begin{array}{cc:ccc} -32 & 0 & 14 & 18 & 0 \\ 0 & -32 & 0 & 14 & 18 \\ \hdashline 0 & 0 & 0 & 0 & 0 \\ 14 & 18 & 0 & -32 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array}\right]\begin{bmatrix} y_1 \\ y_3 \\ y_0 \\ y_2 \\ y_4 \end{bmatrix}=\begin{bmatrix} 0.25 \\ 0.75 \\ 0 \\ 0.5 \\ 0 \end{bmatrix} \tag{11}$$

This places all of the interior degrees of freedom in the top and left of the matrix, meaning that (11) has the same form as (2). Elimination can be formed on (11) to yield

$$\begin{bmatrix} 0 & 0 & 0 \\ 6.125 & -16.25 & 10.125 \\ 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} y_0 \\ y_2 \\ y_4 \end{bmatrix}=\begin{bmatrix} 0 \\ 1.03125 \\ 0 \end{bmatrix} \tag{12}$$

the superelement S_{21} output by P_{21}.

The assembly, remapping, and elimination steps performed on P_{22} and P_{23} proceeds as they did on P_{21}. P_{22} generates the superelement S_{22}

$$\begin{bmatrix} 0 & 0 & 0 \\ 6.125 & -16.25 & 10.125 \\ 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} y_2 \\ y_4 \\ y_6 \end{bmatrix}=\begin{bmatrix} 0 \\ 2.03125 \\ 0 \end{bmatrix} \tag{13}$$

P_{23} generates the superelement S_{23}

$$\begin{bmatrix} 0 & 0 & 0 \\ 6.125 & -16.25 & 10.125 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} y_4 \\ y_6 \\ y_8 \end{bmatrix} = \begin{bmatrix} 0 \\ 3.03125 \\ 0 \end{bmatrix} \tag{14}$$

Now the recursive nature of this algorithm becomes evident. P_{11} receives S_{21}, S_{22}, and S_{23} from its slave processors and due to the elimination that occurred below, is able to treat these as elements as if it were a bottom-level processor. Assembly and remapping at the top level yield

$$\left[\begin{array}{ccc:cc} -16.25 & 10.125 & 0 & 6.125 & 0 \\ 6.125 & -16.25 & 10.125 & 0 & 0 \\ 0 & 0 & -16.25 & 0 & 10.125 \\ \hdashline 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array}\right] \begin{bmatrix} y_2 \\ y_4 \\ y_6 \\ y_0 \\ y_8 \end{bmatrix} = \begin{bmatrix} 1.03125 \\ 2.03125 \\ 3.03125 \\ 0 \\ 0 \end{bmatrix} \tag{15}$$

At this point all seven elements have been condensed into a single element that captures all interior coupling.

The solution stage of the method is ready to begin. Since X_E is now known on P_{11}, that matrix equation can be "resolved," reversing the elimination process, solving for one internal solution on each resolve step. Each resolve step is accomplished by applying the resolve equation (4) from above to the eliminated matrix equation of the prior step. Resolve using (4) yields $y_2=0.625$, $y_4=0.5$, and $y_6=0.625$. Once this occurs, each superelement has a complete internal solution vector, and these are passed back to each bottom-level processor for local resolving. When the whole process is done, the bottom-level processors will contain the overall solution vector $<y_0, y_1, \ldots, y_8>$. Note that this resolve process is performed in parallel according to the hierarchy designed. Each bottom-level processor generates its solution vectors independently for all the coupling was handled higher in the hierarchy. The solution vector for the above example is

$$\left\langle 1 \quad 0.78125 \quad 0.625 \quad 0.53125 \quad 0.5 \quad 0.53125 \quad 0.625 \quad 0.78125 \quad 1 \right\rangle$$

which is exactly equal to the analytic solution.

ADVANTAGES

The recursive substructuring method presented here offers three main advantages over the traditional round robin distribution method of parallel formulation of a finite element or finite difference problem. The first and most important advantage is that of lower communication overhead. As technology advances and individual processors become ever faster, the calculation time for each parallel processor in a multiple processor solution strategy shrinks. In other words, the actual matrix calculations performed in the problem above are not what is time consuming. Rather, the cost lies in the communication time between processors. Indeed, as the number of processors involved in a multiple processor solution strategy increases, total running time tends to equal total communication time. Thus, communication becomes the key bottleneck for parallel speedups, and it is in this area that recursive substructuring excels. By using the elimination method outlined above, a processor can condense any number of local elements into a single superelement, and that superelement is all that must be passed between processors. In the above example, each of the 3 superelements contains 12 pieces of numeric data. That means passing only 36 data prior to the solution phase using recursive substructuring, where the round robin technique, which requires the entire assembled matrix to be passed, would have to pass 90 data prior to solution. In fact, as the number of elements *n* of a discretized problem grows, round robin communication time grows as *wm*, where *w* is the bandwidth and *m* is the number of equations. Each processor must receive each row of a matrix. In contrast, the recursive substructuring communication time grows linearly with the number of processors. This communication overhead advantage is especially important in large problems.

The other advantages of the method are less important but still nontrivial. The back-substitution phase of the problem is done in parallel under the recursive substructuring method, where the round robin technique performs this phase almost serially. The hierarchical structure means that once the solution phase is initiated at the top-level processor, every processor on a given level will be active in resolving their local elements at once. Because of the use of these methods for nonlinear processes where multiple right hand sides are evaluated, this advantage is significant The other advantage of the recursive substructuring method is that load balancing is very flexible because the hierarchy and assembly process can be structured so as to reflect the processors available. One simply makes the faster processors on any level of the hierarchy responsible for more elements.

CONCLUSION

Recursive substructuring, as presented here, was developed to dramatically reduce the communication overhead in parallel formulations of finite element and finite difference problems. Recall that for a given problem, any number of high performance processors can be used to implement a parallel solution. However, communication between these processors remains a fundamental time bottleneck, and it that bottleneck that the recursive substructuring method was designed to combat. As seen above, with a proper hierarchical decomposition of a given problem, the amount of data that needs be passed under the recursive substructuring method is a fraction of what needs be passed using traditional methods. A language to implement this solution method has been separately developed and is being presented in another paper at this conference. The advantages offered by the method's recursive nature and elimination techniques mean it has broad applicability, not only to the global atmospheric circulation model mentioned above, which lends itself easily to such parallel decomposition, but also to other computationally-intensive grand challenge problems.

Comparing a Particle-System Based Simulation to Other Methods in Modeling Special Effects

Joshua Buckner and Ryan Mitchell

Department of Computer Science
Trinity University
715 Stadium Drive
San Antonio, TX 78212

Faculty Advisor:

Gerald N. Pitts, Ph. D.

This paper will compare the efficiency of a particle-system based method of modeling special effects with that of other methods by analyzing the complexity of an implementation of a particle-system based method for simulating wind. The authors researched the complexity in terms of time and main memory usage. The paper includes formulas and graphs pertaining to the order of magnitude of the two types of complexity. The authors will explain each method, but focus on the particle-system based method.

THE PROBLEM

The particle-systems technique was developed by William Reeves for use in the motion picture *Wrath of Khan* [Reeves, 1983]. Since that time, they have been used in rendering methods for producing natural scenery such as trees and grass [Reeves, 1985]. Also, they have been used to simulate such occurrences as wind, fire, and explosions. This paper will focus on the use of particle systems to simulate the action of wind on objects in a real-time, three-dimensional environment.

Particle Systems have recently become a popular method of simulating certain natural occurrences such as fire and wind. With the advent of advanced circuitry in machines designed specifically for video-game playing, the video-game industry has expressed an interest in realistically simulating natural events in real-time to heighten users' sense of immersion in the game experience.

Incorporating a simulation based on particle systems into a real-time, three-dimensional game increases the complexity of the game considerably. Because of the limitations of video-game platforms, complexity must be kept at a minimum. Thus, an analysis of the popular simulation technique of particle systems would be of eminent interest to game programmers. It would aid them in judging the fitness of this particular method against other methods for producing realistic special effects.

THE PARTICLE IMPLEMENTATION

Before analyzing the complexity of a particle-system based wind simulation, the author will describe a particular implementation of such a simulation. Then, the complexity of the algorithm will be analyzed and compared to other ideas for algorithms. Conclusions on the fitness of particle systems for the real-time simulation of wind effects will then be discussed based on the analyses.

Two objectives dominate the design of this particular implementation of a particle simulation of wind. Simplicity and modularity are the watch-words. Simplicity enables the algorithm to be easily understood by the user. It also makes analyzing complexity easier. Modularity provides the algorithm with "plugability". That is to say, this algorithm may be easily incorporated into any real-time, three-dimensional simulation.

BEST COPY AVAILABLE

The implementation was coded in C++, using elements of object oriented programming. Object oriented programming techniques were employed to produce a separate class for a wind manager, a particle, and a base object that may be acted upon by the wind. The use of objects enhances plugablility and is a natural way to represent a system of particles.

The wind manager is responsible for creating particles, removing particles, updating particles with respect to time, and passing messages to "blowable" objects that tell them the wind strength and wind direction in their part of the world. The wind manager keeps the particles in a linked list. The linked list provides a straight-forward method for updating all the particles and finding particles within a particular distance of an object. In order to blow an object, the wind manager finds all the particles within a certain distance of the object, calculates an average direction and strength for the wind in that area, and passes the direction and strength to the object so that it may take the appropriate action, such as falling in a particular direction at a particular speed. The efficiency of this process will be discussed in the next section.

Each particle has a position in the three-dimensional world, a direction to indicate which way it is blowing objects, and a wind strength. A wind front is initiated by creating a collection of particles with directions and strengths all within specified variances. These variances are defined in the above mentioned wind manager which is responsible for the creation of the particles.

The base object for blowable objects is responsible for containing the position of an object, its susceptibility to wind, and for providing a place to define an action that occurs when the object is blown (implemented as a virtual function in C++ parlance). The user will implement a specific object by inheriting the base class, defining the movement function of the object, giving the object a position in the world, and including whatever three-dimensional, graphics-specific code needed to render the object.

COMPLEXITY OF THE PARTICLE IMPLEMENTATION

The process of simulating wind consists of three tasks. These tasks are creating the particles, updating the particles with respect to time, and applying the wind to the objects. All three of these tasks are carried out by the wind manager. The wind manager directly executes the task of creating the particles; the wind manager uses messaging to affect the updating of particles and the blowing of objects. Each of these tasks will be discussed in turn in terms of complexity.

The first action that takes place in the creation of wind is particle creation. As stated before, each particle object contains a position in the three-dimensional world, a direction to indicate which way it is blowing objects, and a wind strength. The amount of storage required by each particle is thus, three integers for the position, three integers for the direction, and one integer for the strength. Also, each particle contains a link to the next particle in the list, an integer. This is in addition to the wind manager's own three-integer position, two integer variances for controlling the particles' stochastically generated strength and direction, an increment for updating a particle's position, a decrement for updating a particle's strength, and an integer pointer to the first particle in the list of particles being generated. Let i represent the amount of space taken up by an integer in main memory and n represent the number of particles being generated. Then, the overall storage incurred by the creation of particles may be stated as the following formula.

$$8i + 8ni \qquad (1)$$

As can be clearly discerned from the formula, the overwhelming factor in determining the amount of storage needed by the creation of a wind front is the number of particles making up the front.

The amount of time it takes to create particles is determined by three separate functions carried out by the wind manager. These tasks are the time it takes to allocate storage for each particle, the amount of time it takes to stochastically generate deviances for the wind-direction and strength of each particle, and the time it takes to add these deviances to the predefined initial values of the wind-direction and strength of each particle. If the wind manager generates n particles, m is the time it takes to allocate space for one particle, r is the time it takes to generate one random number, and a is the time it takes to add two integers together, then the following formula determines the time-complexity of wind-front generation.

$$n\,(m + 4r + 4a) \qquad (2)$$

From the formula, it may be concluded that the time it takes to generate a wind-front in this manner is of order of magnitude of the number of particles generated.

Now that the wind manager has created a list of particles, it must keep track of those particles and update them with respect to time. The updating process consists of traversing the whole list of particles at specific intervals of time and decrementing the strength of each particle. This process requires no storage of new variables, and so the formula for the amount of storage remains the same. However, the time it takes to decrement the strength must be accounted for in the time complexity formula. This decrementing amounts to the addition of one integer to another integer. Also, each particle will have moved a certain increment of distance. This increment must be added to the particles position. Three more integer additions are required for the wind manager to accomplish the updating of a particle's position. Resolving the addresses represented by the links in a linked list becomes an issue within the context of time complexity in an implementation involving dynamic memory and many particles. But, since this issue is implementation specific, address resolution will not be included in the time complexity formula. Let t be the total time the simulation runs, and u be the number of updates to be carried out over the simulation's lifetime. The overall time-complexity for the simulation now becomes the following, in light of the updating process.

$$n\,(m + 4r + 4a + 4tua) \qquad (3)$$

This addition of another a term doesn't change the overall order of magnitude of the time-complexity, as one can see from the equation.

The wind manager's accounting mechanism for particles thus considered, attention must now turn to the point of the whole simulation, causing wind to act on the objects in the simulated environment. No new variables are to be stored, so the memory model remains the same. To cause an object to be blown, the wind manager must search the list of particles. This search determines which particles are in the object's area. The object's area is defined by a radius stored as the object's susceptibility to wind. Then, the average of the nearest particles' wind directions and wind strengths is calculated by the wind manager. The search requires comparing each particle's position to the predetermined boundary as well as the resolution of addresses in traversing the linked list. Again, this issue is implementation specific. Address resolution will not be included in the time complexity formula. This translates as three comparisons per particle. Also, the object itself must carry out the movement caused by the wind. This movement is in the form of sampling some formula used to determine the path of the object's translation in three dimensions. Let c be the time it takes to compare two integers, b be the number of times an object is acted upon in the simulation, and f represent the time-complexity of an object's movement function. The time complexity formula becomes the following.

$$n\,(m + 4r + 4a + 4tua + 3bc\,) + bf \tag{4}$$

The order of magnitude of the memory-complexity and the order of magnitude of the time-complexity have not changed.

The overwhelming factor in the complexity of the particle-system based wind simulation, both in terms of time and memory, is the number of particles generated. See Figure 1 below. The number of particles determines the degree to which this simulation is stochastic. The fewer the particles, the smaller the sample used in determining the direction and strength of wind acting upon an object. Random variance and complexity are in opposition in the simulation of wind in this implementation.

OTHER IMPLEMENTATIONS AND THEIR COMPLEXITY

Many other possibilities exist for simulating wind. One possible implementation involves keeping a table of static grid-points. These grid-points hold a wind direction and wind strength. The wind is changed by initiating an update of the points along the first row of the grid. Then, the next row updates its values using the values of the previous row. The process continues until all the rows have been updated. The time and memory complexity of this implementation would thus depend on the number of points, analogous to particles, on the wind grid. See Figure 2 below.

Another possibility for simulating wind is defining wind only where objects occur. In this implementation, objects carry their own wind direction and wind strength which are updated by the wind manager. The wind manager keeps a list of objects. This eliminates the need for an intermediate particle or grid-point object and deals with the rendered objects directly. The time and memory complexity of this implementation would only depend on the number of blowable objects. See Figure 3 below.

CONCLUSIONS

The graphs below indicate that ultimately the complexity is dependant upon the detail of the wind simulation. The less detail included in the simulation, the less complex the simulation. The programmer must keep this in mind when programming with time-complexity limits.

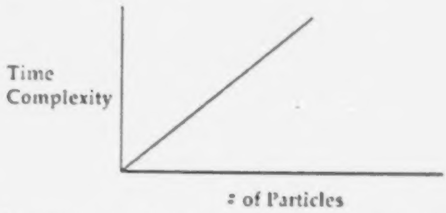

Figure 1: Complexity of the Particle-System Model for Wind

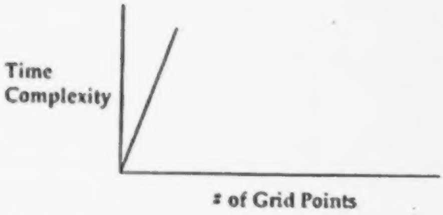

Figure 2: Complexity of the Grid Model for Wind

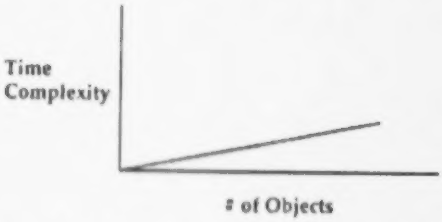

Figure 3: Complexity of the Object Model for Wind

The real-time simulation of wind using particle systems is easily implemented but, depending on the amount of unpredictability desired, can be computationally intensive. Other methods depend on other factors, which may or may not lead to less computational complexity than the particle-system method. The programmer must pick the method best suited to the needs of the simulation.

An Examination of Mentoring Methodologies in Object Technology

Janet E. Cody-Mehaffey

Department of Computer Science
The University of North Carolina at Asheville
Asheville, NC 28804-3299

Faculty Advisor: Mary Lynn Manns

Object technology (OT) is the newest and most promising method for developing computer systems. However, a shortage of OT experts is forcing many organizations to "retrain" their employees in this new paradigm. One instructional method which holds much promise for accomplishing this tedious retraining process is mentoring. This research examines the effectiveness of those who do mentoring. Through telephone interviews, data were collected from organizations which use mentors in their OT training process. In order to determine the most effective uses of a mentor's time, the study looks at the various tasks the mentors perform and which of these are seen as effective and ineffective by both the mentors and developers. The results provide organizations with guidelines for allocating their mentors' duties during the training process.

INTRODUCTION

In a field of constant change, object technology (OT) is the newest method for developing computer systems. Proponents claim that OT can save organizations time, resources, and money. OT decreases development time because it facilitates the reuse of previously developed systems. It also allows applications to be easily modified to adapt to changing requirements of users or to increase the useful lifetime of the application (Fayad, 1995).

OT evolved out of, but works on different principles than, structured programming. Alan O'Callaghan, chair of the Object Technology Group at DeMontfort University, states: "The problem is that OT combines the old and the new in a completely new configuration" (O'Callaghan, 1996). Problems arise when developers feel that because they are experts in structured programming they should be capable of switching easily to OT. This is not usually true. According to O'Callaghan, "it is the people most steeped in structured methods who bend their fenders most often in my experience" (O'Callaghan, 1996). Making the paradigm shift to OT requires developers to look at every aspect of the system in a new light.

Although OT seems to be a beneficial way to develop systems, there is a shortage of people who are considered experts in this technology. Therefore, organizations are finding it necessary to "retrain" their current staff in object-oriented (OO) techniques (Gaudin, 1996). This "retraining" is not easy and can be quite expensive. The learning curve is long and steep for the employees ingrained in procedural system development methods. In order to relax this learning curve, an organization often finds it necessary to follow-up intense classroom training with a technique known as mentoring. Mentors can come from within an organization's pool of employees who are considered to be the experts in OT or from outside consulting companies.

Mentoring as a form of instruction has been used for centuries. The most famous historical instance is detailed by Homer in the Odyssey. During the ten years Odysseus was in Troy, Mentor acted as teacher, advisor, friend, and surrogate father to Telemachus, son of Odysseus. The use of this mythological story was important in facilitating relationships between Greek boys and older males. During the Middle Ages, master craftsmen taught their skills to students under the guidelines of the apprenticeship programs. This trend continues throughout history into modern times where the complexity of tasks lends itself to the benefits of learning from a master (Murray, 1991).

Mentoring is an instructional method which holds a great deal of promise in OT. Jason Browning, a member of the technical staff at AT&T Bell Laboratories, believes that "having a mentor show you the OOP ropes enhances any formal training" (qtd. in

Radding, 1995) Eric Lazarus, an independent object technology consultant, points out in the Journal of Object-Oriented Programming that wise managers are using mentoring to help developers learn not only the concept of objects, but development tools and languages unique to OT (Lazarus, 1995) According to a study presented at the 1995 Conference on Teaching and Training in the Technology of Objects, a significant number of organizations feel that "there is no better way to learn OT than mentoring" (Manns, 1995) Two reasons stand out to explain why mentoring is so valuable First, mentoring allows training to take place in small groups of one to ten trainees giving personalized, individual attention Second, it provides the opportunity for the developers to complete a project at the same time they are being trained

The process of mentoring has been described as involving "part intuition, part feelings, and part hunch -- made up as you go along, and composed of whatever ingredients you have available at the moment" (Shea, 1992) However, some of those involved in training developers in OT believe that mentoring should be more than that Therefore, many training and consulting companies for OT have developed more concrete styles for implementing their mentoring programs

Unfortunately, documented styles for mentoring in OT are limited and not easily labeled Lazarus believes that mentoring methods range from "highly structured," similar to a classroom format, to allowing mentors to function as "on-site gurus, available to be consulted . . . when a problem arises" (Lazarus, 1995) Although many different methods are currently being used, the OT field has yet to document which methods are most effective According to Lazarus, "we may find that the wise choice of a mentoring method is often more critical to the success of a project than the details of the object model, the choice of language and tool set, or other more technical aspects of the effort" (Lazarus, 1995) In order to begin determining which OT mentoring methodologies are most effective, the techniques used to mentor must be documented in relation to the change in OT skill level of the developers As Lazarus states, "if we are going to train new mentors, we have to know what it is that effective mentors do" (Lazarus, 1995)

In summary, the training of developers in OT is a difficult process One method which has been shown to hold great promise for decreasing this difficulty is mentoring To date, no one has documented an effective way to mentor OT developers Lazarus states that "a serious study and comparison of the wide variety of mentoring approaches . . . will be immeasurably helpful in [improving the quality of mentoring]" (Lazarus, 1995) This research will make progress towards this end by answering the following research questions

> What are some of the traits in mentors who teach object technology? Which of these traits do the mentors and developers see as effective for decreasing the steep learning curve for object technology?

METHODOLOGY

This research begins to determine some of the successful mentoring methods that organizations are using to teach OT Towards this end, twenty people involved in twenty different OT projects were interviewed about the mentoring process Ten of these where mentors and ten were developers who had received mentoring The subjects volunteered to participate by either responding to a message posted to various Internet news groups soliciting participants for the study, or by replying to a personal e-mail message inviting them to take part in the study All were surveyed by telephone in a ten to fifteen minute conversation Each participant was asked the same 13 questions, although the wording of the questions varied depending on whether the participant was a mentor or a developer who had received mentoring The questions targeted the specific tasks of the mentors and their effective and ineffective traits (See Appendix A for developer's version of survey) The analysis of the data involved searching for similarities between what the developers and the mentors saw as effective and ineffective traits among mentors in OT

FINDINGS

The first part of the survey asked ten mentors to state the specific tasks they perform when mentoring in their OT project The second part asked ten developers who were mentored during ten different OT projects to report on the tasks their mentors

BEST COPY AVAILABLE

performed. The responses of these two groups appear in Table 1. The first column states the tasks and the second and third columns show the number of mentors and developers who reported each task. It is noted that the three most frequently appearing tasks are more interactive than the others on the list. This coincides with the philosophy of mentoring, which is a more interactive, less formal, teaching style.

Table 1. Specific Tasks OT Mentors Perform

Task	Mentors	Developers	Total
Reviewing designs w/ trainees	9	10	19
Coding w/ trainees	7	8	15
Discussing project requirements w/ trainees	9	3	12
Designing alone	6	5	11
Coding alone	6	4	10
Stand up lectures	7	2	9

The survey also included an open ended question requesting other tasks the mentors performed. Fifteen different tasks were identified. The majority of these fifteen were only reported by one survey participant. However, five mentors reported that they also were involved in project management. Four developers stated that their mentors also were involved in general coaching, guidance, and feedback. Three survey participants reported that the mentor was involved in either setting standards / methodology, or performing review / audits. Other tasks included helping with system architecture, system analysis, documentation, and forming lunch time talks.

In the second part of the survey, mentors and developers reported effective and ineffective traits in OT mentors. From the mentors' points of view, the most frequently reported effective traits included the ability to relate the work back to the principles being taught, to understand the skill level of the developers, to make the process exciting, and to understand the business side of the organization. Ineffective traits included an inablity to overcome reluctance on the part of the developers, a lack of tolerance and patience, and an inability to effectively estimate time.

From the developers' points of view, their mentors' effective traits included interpersonal skills, a commitment to passing on knowledge, guidance which allowed the developer to work alone, and accessibility and approachability. Ineffective traits primarily consisted of teaching OT with an organizational slant, poor listening skills, and inaccessibility and preoccupation.

One can conclude, from this limited sample, that the most effective traits of mentors are those that are most interactive with the developers. These traits allowed the mentors to understand developers' needs and facilitate the ability to meet these needs. The most ineffective traits of the mentor are those that are less interactive, often occurring in structured classroom training. Therefore, among the twenty individuals in this study, a mentor's ability to interact was seen as having the most effective outcome on learning OT.

LIMITATIONS OF STUDY

The major limitation of this study was the small sample size of only 10 mentors and 10 developers. A larger sample size would have yielded more data, but was not used because this was an exploratory study. Before this study, only anecdotal information was available on the various tasks of mentors, making it difficult to know what to ask the survey participants. Now, this research provides a fairly comprehensive list of the tasks mentors perform and their effective and ineffective traits.

SUMMARY and CONCLUSION

OT is a way of developing computer systems that offers a viable solution to the inadequacies of procedural programming, saving organizations time and money. Although it seems to be a beneficial way to develop systems, there is a shortage of people who are considered experts in this technology. The training of developers in OT is a difficult process with a long and steep learning curve. Mentoring as a form of instruction has been used for centuries and is a method which has been shown to hold a great deal of promise for decreasing the difficulties in training OT developers. To date, no one has documented an effective way to mentor OT developers. This research is the first step in documenting some of the tasks that mentors actually perform, and some of the effective and ineffective traits of these mentors. This information is of value to those facing the difficult task of retraining in the OO paradigm.

APPENDIX A: Developers Mentoring Survey

All of the questions on this survey should reference the most recent OT project in which mentoring was used to train employees in OT in your organization.

General OO Questions

1) For what type of application was this project developed?
2) What object language(s) did the organization use for this project?
3) What object methodology(s) did the organization use for this project?

Questions about Mentoring Program

4) Why did you choose to use a mentor in this project?
5) Was your mentor supplied from within the organization or from a consulting company?
6) a) If in-house --
        1) What is your organization's criteria for choosing someone to be a mentor?
        2) How did your in-house mentor learn to be a mentor?
    b) If from a hired training / consulting company --
        1) How did you choose the company?
        2) What experience did this organization claim to have in mentoring?
7) What was your approximate mentor to developer ratio in this project?
8) Through what point did the mentor remain on the project?
9) What tasks did your mentor perform in this project?
    _____ coding alone
    _____ coding with trainee(s)
    _____ stand up lecture
    _____ designing
    _____ reviewing designs with trainee(s)
    _____ discussing project requirements
    _____ other (describe ______________________________)
    _____ other (describe ______________________________)
    _____ other (describe ______________________________)
10) Rate the OO skill level of each person before and after the project.

	Before Project	After Project
	1-- beginner to OO	1-- still fumbling with OO
	2-- some formal training (but no OO project experience)	2-- some contribution to project
	3-- some OO project experience	3-- key contributor to project
person 1		
person 2		
person 10		

Opinions about Mentor

11) On a scale of one to four, how would you rate the success of your mentor as an OT trainer?
    (With one being least successful, and four being most successful.)
    1   2   3   4
12) Which of your mentor's skills do you believe were the most effective for training your employees?   Explain
13) Which of your mentor's skills do you believe were the least effective for training your employees?   Explain

3D Special Effects:
Modeling Reflective Surfaces In Real-Time

Daniel P. Cornell

Department of Computer Scienc
Trinity University

San Antonio, TX 78212

Faculty Advisor:
Dr. Gerald Pitts

The advancement of special effects for real-time graphics has greatly enhanced the realism of virtual reality worlds. These real-time simulations offer virtual reality modelers a dual challenge: create a scene that is both well-detailed and fully interactive with the user. In the real world, glass and other surfaces reflect light sources to produce glare. To model this effect, a non-interactive approach would be to integrate static glare into the initial modeling of objects. Other techniques such as ray tracing produce photorealistic images, but are far too computationally expensive to be of practical use in real-time. This paper examines several approaches to dynamically model this effect in a computationally feasible manner. A single-color bitmap could be rendered over the reflective surface. Changing this effect's location with the position of the viewer might produce acceptable results. A pre-defined texture of a reflection image could be mapped onto the reflective surface. This environment mapping could be made dynamic by tying the texture coordinates to the viewer's location. A final technique would involve rendering a modified view of the scene to a pixelmap texture, which could then be mapped onto the surface. Algorithms developed to implement the three solutions above will be outlined, and, ultimately, graphic demonstrations of these algorithms will be provided for comparison.

INTRODUCTION

Special effects for virtual reality applications have greatly enhanced the immersion into modeled worlds. In real-world situations, phenomenon such as smoke, glare from lights, and images in reflective surfaces are commonplace, occurring naturally; in virtual worlds, these effects must be specifically implemented, often at significant computational expense. Special effects provide the 'finishing touches' that round out virtual reality models, providing nuances lending to the immersive nature of the experience. Therefore it is desirable to successfully model these effects in a computationally reasonable manner.

Specifically examined in this paper are reflective images. Traditional methods for modeling these occurrences could involve adding static reflection images to the initial model. These images do not change with the viewer's perspective so, although they might appear realistic when the viewer is motionless in relation to the reflective surface, changes in relative position reveal the inadequacy of the model. Techniques such as ray tracing are capable of modeling reflections with photorealistic accuracy. Unfortunately, these methods are so computationally expensive that it is impossible to perform them in real-time, thus making them useless for virtual reality models. Current solutions to this problem are either too rudimentary to be effective, or too costly to be reasonable. This paper proposes three possible solutions spanning the realism-efficiency spectrum. These solutions are implemented using the OpenGL rendering engine and the OpenGL Utility Toolkit windowing interface.

Example code for each of the algorithms developed in this paper is available at http://www.cs.trinity.edu/~dcornell/research/reflect/. Each of the sample programs place a viewer in a simple virtual world consisting of a reflective surface and three cones which can potentially be reflected in this surface (See Figure 1). The reader is encouraged to see the individual sources for specific details.

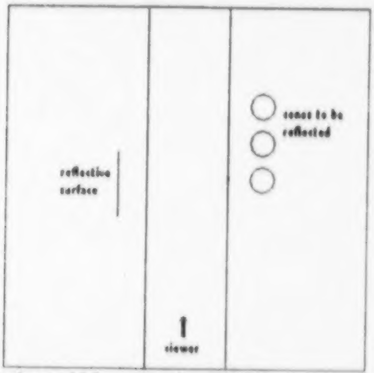

Figure 1: Layout of example world from sample programs

RANDOMIZED PIXEL RENDERING

The most significant problem with integrating reflection images statically into object models is the lack change in reflected images. In the real world, reflection images change as an individual moves. Motion in the world results in a corresponding alteration of the reflected image. Statically modeled reflected images do not change with a change in the viewer's position. Linking a change in reflected image to a change in viewer's position is the first step in creating realistic reflection models.

Modifying the reflected image with changes in the viewer's position can be accomplished by randomly rendering pixels over the reflective surface every time the viewer moves. With each change in the viewer's location, new pixel locations are calculated and these pixels are then rendered over the image of the reflective surface in the scene.

An implementation of this algorithm is available in the file `pixel.c`. This implementation operates by selecting points randomly located within an acceptable range (the extents of the reflective surface) and plotting small triangles in the scene based on these points. Triangles were rendered into the scene rather than points because they covered a larger area of the reflective surface, thus fewer random numbers needed to be generated to complete the reflective image. Every time the viewer's position is incremented, new triangles are calculated and rendered in the scene. In this way, changes in the viewer's position result in changes in the reflected image (See Figure 2).

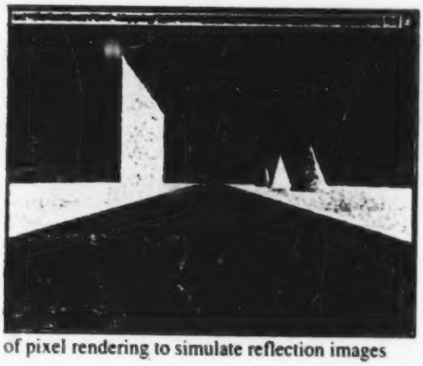

Figure 2: Screen shot of pixel rendering to simulate reflection images

In this implementation, the triangles are colored the same as objects they might potentially reflect, and the random numbers are skewed in an attempt to more accurately mimic a reflected image. However, as a whole these measures are unsuccessful. Although the image does change every time the viewer's position changes, it is rather obvious that the modifications to the image are not an accurate reflection of the scene objects. The effect produced is more similar to television static than a reflection. This inconsistency between the reflected image and the scene objects makes this algorithm, in its present form, unacceptable for use in most situations. For reflective surfaces which cover a very small scene area, or in situations where the viewer is moving very fast relative to the reflective surface this 'quick and dirty' algorithm might provide acceptable results. However other solutions are needed for more common situations.

ENVIRONMENT MAPPING USING DYNAMIC TEXTURE-COORDINATE GENERATION

The foremost problem with the preceding algorithm was the lack of the reflection model's connection to the objects in the scene. In static scenes, a technique known as environment mapping can be used to simulate reflective surfaces. In environment mapping, an image of the reflected portion of the scene is texture mapped onto the reflective surface (Neider, Davis, and Woo, 1993). To make this reflection effect interactive, the texture coordinates of the reflection texture can be changed along with the viewer's position (See Figure 3). If done properly, the image can be made to slide along the reflective surface, simulating the motion of reflected objects as depicted in the reflected surface.

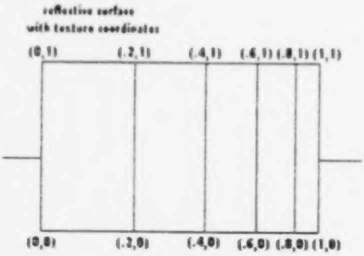

Figure 3: Polygon with skewed texture coordinates which will result in a distorted texture image

An implementation of this algorithm is presented in the file `environ.c`. In this example, the reflection image is a modified view of the scene where the viewer is located at the center of the mirror looking out in the direction of objects in the scene which will appear in the reflected image. This 64 by 64 pixel image was rendered by the `capture` program and saved to the file `image.64`. This file was then read into the `environ` program and set to be the current texture. The reflective surface, in this model, is actually five rectangular polygons. The coordinates of these polygons are determined by a 1dimensional free-form deformation algorithm which 'slide' the texture across the reflective surface. In the deformation algorithm, three control points define the locations of a list of points based on the original locations of these points. The moving points, in this case, are the interior vertices of the system of coplanar polygons modeling the reflective surface. The algorithm, taken from (Vince, 1995) is as follows:

Given 3 control points C0, C1, and C2, and 4 ordinates P1, P2, P3, and P4, after a change in one or more of the control points:

$$P' = (1-u)^2 C_0 + 2u(1-u)C_1 + u^2 \quad (for\, 0 \le u \le 1) \qquad [1]$$

where:

$$u = \frac{P - P_1}{P_4 - P_1} \qquad [2]$$

The control points were made to be a function of the position of the viewer, thus the texture coordinates on the reflective image also change with the viewer's position (See Figure 4).

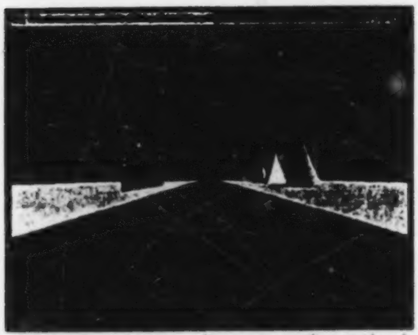

Figure 4: Screen shot of dynamic texture coordinate generation to simulate reflection images

This algorithm overcomes the basic problem with the first: a need for a tie between the reflective image and the reflected objects in the virtual scene. Because the texture-mapping image is a potential reflective image, it is clear that the objects depicted in the reflective surface are linked to the other objects in the scene. The distortion of the textured image on the reflective surface simulates the alteration of the reflection image that would be perceived by an individual in the real world. However, as the viewer nears the reflective surface, the extent of distortion of the textured image begins to reveal inconsistencies between the reflective image and what the viewer would expect to see. This algorithm ran significantly more slowly than the pixel-mapping algorithm presented previously due to the texture-mapping required to render the reflection image. Overall, though, the results of this algorithm were much more encouraging than those of the previous.

ENVIRONMENT MAPPING USING MODIFIED SCENE VIEW RENDERINGS

Building upon previous success in using texture mapping to simulate reflection, the third and final algorithm models the reflected image using a reflected image texture changes every time the viewer changes position. Whereas the previous algorithm used a single texture image that was distorted based on the viewer's position, the texture image in this algorithm is mapped undistorted onto the reflective surface polygon, but the texture is regenerated each frame based on the viewer's position. Each texture image will be an altered view of the scene where the viewpoint is located at the center of the reflective surface and is facing in the direction of a ray originating from the viewer and reflecting off of the center of the reflective surface (See Figure 5).

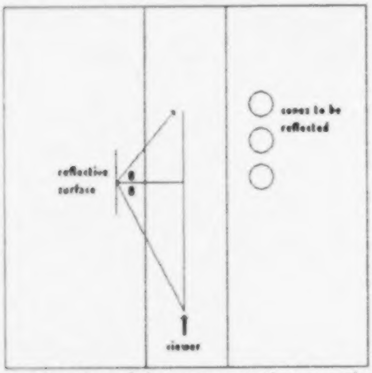

Figure 5: Location and view direction of alternate scene viewer used to render the reflected scene texture image.

This algorithm truly captures the 'feel' of the reflection as the viewer moves past the reflective surface. Not only does the image change with the viewer's position, it is also clearly linked to reflected objects in the scene, and the changes in the reflective image correspond to the relative positions of objects in the scene (See Figure 6). This realistic performance, however, relies on additional scene rendition and texture mapping, dropping the speed of this algorithm below that of the previous two, but still fast enough to be used in real-time applications.

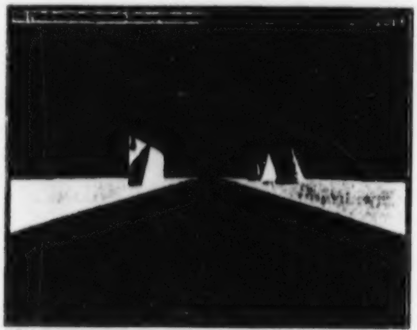

Figure 6: Screen shot of dynamic texture generation and mapping used to simulate reflections

TOPICS FOR FURTHER RESEARCH

These algorithms were all tested on a Silicon Graphics Indigo^2 Extreme and a Silicon Graphics Iris Crimson Reality Engine. Although the algorithms performed in real-time, the dedicated graphics hardware found in these machines may de-emphasize the computational complexity inherent in these types of three-dimensional rendering situations. Because of the portable nature of OpenGL and GLUT code, the sample programs associated with this paper could be easily ported to any number of platforms and tested for performance there.

For the purposes of this paper, all algorithms have been implemented giving the viewer only one degree of freedom. For use in any real-time graphics package, these algorithms would need to be expanded to take into account additional freedoms the viewer might have. The pixel-mapping algorithm could most likely be used as is, but the latter two algorithms using texture mapping would require rotations to the mapped texture in order to properly orient the reflective image in the scene.

The experiments based on these algorithms indicate that it is possible to model reflective surfaces in both an attractive and computationally feasible manner. In modeling these reflected images it appears there is a trade-off between model quality and algorithm speed, forcing the designer to choose an algorithm according to the demands of the situation.

Formal Methods for Software Specifications: A Case Study

Michelle Dillinger

Faculty Advisor:

Ken Abernethy

Formal methods for software specification employ formal logic to model requirements for computer systems and software. The goal of this paper is to explore the process of capturing software requirements specifications in the formal specification language PVS, employing a system modeled as a finite state machine. The problem modeled is the control system for a microwave oven. The specifications for this system include support for nine tasks (or modes) and six inputs. The development of this case study was a part of a larger NASA JOVE funded research effort focused on the issue of technology transfer of formal methods for software specifications.

INTRODUCTION

Formal methods for software specification comprises a new method for capturing system or software requirements and offers many advantages over English specifications. Formal methods are based on formal logic and mathematics. The methods vary in their form and rigor. The least rigorous being English specifications with occasional mathematical notation embedded in them. The most rigorous is fully formal specifications in a formal specification language with a precise semantics. Most specifications are somewhere in the middle.

Formal methods offer many advantages for capturing software requirements. First, creating and maintaining software-intensive systems is difficult. However, formal methods make it easier to create more precise and less ambiguous system specifications and simplify maintenance by providing a more structured specification. Secondly, formal specification methods can discover defects in a system earlier in the system life cycle. This allows the analysts to check for consistency and other errors before the specification enters the design, implementation, testing, and maintenance steps of the life cycle. Finally, defining the specifications formally makes it easier to achieve consistent and correct specifications since they can be checked in a repeatable manner. Since the specification is formal, the same problem analysis can be repeated by several different people with the end product being the same.

There are various formal methods tools, such as PVS (Prototype Verification System) and Z. A general formal methods tool consists of a formal specification language, a parser, a type checker, and a proof checker. The language allows the user to model and formalize the specification. The parser checks to see if the specification is syntactically consistent, and is an automated process. The type checker is also automated and checks for semantic mistakes. The proof checker requires the user to employ proof strategies, and results in a verified specification.

The example in this paper is captured in the formal method language PVS. PVS or prototype verification system was developed at Stanford Research Institute, International (SRI). It includes all of the processes that a general tool would include: language, parser, type checker, and proof checker.

The overall goal of this research is technology transfer. One of the obstacles to widespread use of formal methods is the substantial learning curve encountered. A focus of the NASA JOVE project is on creating materials that will enhance formal methods training and education. The case study presented here will be used as a meaningful example in training materials.

THE ENGLISH SPECIFICATION OF THE CASE STUDY PROBLEM

The objective of this example is to develop a formal specification for the control system of a microwave oven. The system is to be modeled as a finite state machine. The control system supports nine tasks and allows six inputs. Figure 1 illustrates the control panel for the system.

HIGH
MEDIUM
LOW

Figure 1: The microwave oven control system display panel.

The functions of the microwave control system are defined by the following requirements:

1. The microwave panel contains nine buttons for selecting tasks for the system, and one display for entering or displaying values, one at a time, for six different possible displays. The system supports the following nine tasks:
    - Start
    - Clock
    - Timed Cook
    - Defrost
    - Temperature
    - Level
    - Rotate
    - Set Start Time
    - Stop

   Only one of Clock, Timed Cook, Defrost, Temperature, or Stop may be engaged at one time. One of those should be engaged at all times. The default should be Clock. When one of these is engaged, any of the others that is engaged should switch to a disengaged mode. If the user attempts to engage the same button already engaged, the action should be ignored. Set Start Time may be engaged with Timed Cook, Defrost, or Temperature.

2. There is one display on the panel, but it supports six different display tasks. Only one display can appear at a time. The following displays are supported:

    - time
    - duration
    - level indicator
    - rotation interval
    - temperature target
    - start time

   The display modes show default values or input values. The time should be displayed if no other value is displayed or being entered. Time is used to display or set the current time. The default value is the system time. Duration displays or sets the number of minutes that one of the task is to be performed. The default value is zero seconds. Level indicator is used to display or enter one of three cooking levels: high, medium, or low. The default is high. Rotation interval sets or displays the number of seconds after which the turntable should rotate. The default is zero seconds or continuous rotation. Temperature target is used to enter or display the temperature at which the microwave should stop cooking. It requires a cooking probe to work. The default value is zero degrees, so the function will not operate unless a valid temperature is input. Start time sets or displays the time at which the microwave is to begin cooking. The default value is 0:00, so this function also does not work unless a valid value is input.
3. If the user enters a rotation interval of less than 15 seconds, the system defaults to continuous rotation.
4. Level may be engaged with start, Timed Cook, Temperature, defrost, or Set Start Time and with rotate.
5. Rotate may be engaged with start, Timed Cook, Temperature, defrost, or Set Start Time and with level.
6. After Set Start Time is engaged and a start time is selected or entered, any of the other legitimate combinations can be engaged.
7. Engaging the clock when Set Start Time is engaged cancels Set Start Time and any other buttons that are engaged.

EXCERPTS FROM THE PVS SPECIFICATION

The system is modeled as a finite state machine in PVS. To structure the specification, one defines the relevant types, building to the definition of the state transition function. Once the state transition function is defined, one can then define some properties that this function should have (i.e. system properties). Note that all characters following a % on a line represent comments.

```
% ************PVS SPECIFICATION EXCERPTS****************************
% The problem is modeled as a state machine. (Note % indicates comment)
% Our basic state transition function will be of the following form
% Sn = nextstate(Ac,Sc)          Sn stands for the next state
%                                Ac is am action, Sc is the current state

% Define the actions type
        actions: TYPE = {press_start, press_clock, press_timed_cook, press_defrost,
        press_temp_cook, press_level, press_rotate, press_set_start_time, input_time,
        input_duration, input_lev_ind, input_rot_int, input_temp_targ, input_start_time,
        temp_reached, duration_finished, start_time_reached}
```

           ENDIF
        ELSE
           st          %% Ignore
        ENDIF

% ETC - remaining transition function definitions are omitted

% After defining the initial state st0 and a boolean fuction valid_state(st) - returns either
% True or False - to decide when a state is valid, one can capture some of the system's
% basic properties with some putative theorems which can be verified by the PVS
% theorem prover. The following examples illustrate this technique

% The initial state is a valid state
st0_good: THEOREM valid_state(st0)

% The nextstate transition function preserves the valid state property
nextstate_good: THEOREM valid_state(st) IMPLIES valid_state(nextstate(ac, st))
```

FINDINGS

This research exposed the advantages and disadvantages of using formal methods. During the analysis and specification of the problem, various deficiencies were revealed. Questions arose about the actual way some transitions would take place and the purpose of those transitions. The formal specification help to expose redundant functions developing two different functions to perform the same task with the timed cook and the delayed cook. Other problems that occurred were with the rotate and level tasks. These two tasks had not been defined thoroughly and would have caused extensive work to be necessary if the specification were not in a formal language. The modifications were easily made due to the formalized specification. Since the specification is formal, it forces the analyst to consider every possibility because it requires the specification of almost all details. The only disadvantage found was the learning curved involved with formal methods. Learning the syntax and how to use the software both require some extensive study.

SUMMARY AND ACKNOWLEDGMENTS

In conclusion, modeling the microwave control system as a finite state machine was straightforward and helped refine the understanding of the underlying problem. Translating the state machine model to a PVS specification revealed deficiencies in the state machine model. The problem provides a meaningful and accessible example of formal specification capture in PVS, and should prove useful in introducing software engineers to formal methods of software specification.

ABSTRACT

This paper concentrates on two truth maintenance techniques, an Assumption-based Truth Maintenance System (ATMS) and a Contradiction-based Truth Maintenance System (CTMS), and shows how these techniques accomplish the verification of a knowledge base (KB).

Verification deals with the identification of different types of abnormalities and errors that may occur in a KB. It is very important to ensure the detection and removal of all errors during KB development. Traditional verification techniques, based upon comparing pairs of rules with conflicting or identical conclusions, require test cases to reveal errors. Such test cases, often unavailable especially during early development, cannot assure the detection of all logical and structural errors. The TMS techniques generate test cases automatically or logically deduce all explicit and hidden inconsistencies and circularities in the KB.

This paper compares the ATMS and CTMS techniques and focuses on circular rules and logical inconsistency.

INTRODUCTION

A knowledge base (KB) can be represented by a set of production rules. A few examples of such rules are, $A \Rightarrow B$, $C \wedge D \Rightarrow E$, and $\neg F \Rightarrow G$. These are read as, A implies B, C and D implies E, and not F implies G.

Verification deals with the identification of different types of abnormalities and errors that may occur in a KB. It is very important to ensure the detection and removal of all structural errors during KB development. The most important errors are circular rules, redundant rules, and inconsistent rules. A circular rule, when satisfied, causes a loop to occur. A redundant rule's presence or absence makes no difference. An inconsistent rule, when satisfied, will imply a contradictory conclusion.

The purpose of a Truth Maintenance System (TMS) is to solve, or assist in solving, problems. Such a system, depending on its role in the problem solving process, belongs to one of two groups. The first group contains those systems, considered to be data base management systems, that do not have the ability to make inferences. Inferences are conclusions drawn from facts. The Assumption-based TMS (ATMS) belongs to this group. The second group contains those systems that incorporate some inference facilities allowing them to act on their own. The Contradiction-based TMS (CTMS) belongs to this group.

The remaining sections provide an illustration and comparison of the ATMS and CTMS techniques without presenting the details of the TMSs.

ATMS TECHNIQUE

KB verification can be done by using Knowledge Base Reduction (KBR). KBR is a process that translates the existing knowledge base theory (KB-theory) into the so-called reduced theory which is a kind of ATMS theory. The KB-theory is defined as a pair (F,R) where F is a set of facts and R is a set of rules of the form: $P1 \wedge P2 \wedge \ldots \wedge Pn \Rightarrow H$. P1,P2,...,Pn are premises of a rule and are referred to as the left hand side of a rule. H is the hypothesis which the rule implies and is referred to as the right hand side of a rule.

The following is an example of a KB-theory.

Facts:

N2,N3,N18.

Rules:

R1: $N2 \wedge N3 \Rightarrow N4$
R2: $N2 \Rightarrow N10$
R3: $N18 \Rightarrow N11$
R4: $N18 \wedge N10 \Rightarrow N4$
R5: $N4 \wedge N11 \Rightarrow N13$
R6: $N2 \Rightarrow \neg N13$
R7: $N2 \Rightarrow \neg N11$
R8: $N10 \wedge N3 \Rightarrow N4$.

Hypotheses:

N4,N10,N11,¬N11,N13,¬N13.

The first of two steps consists of dividing the set of rules into disjoint sets, called rule levels, according to a depends-on relation. Rule1 depends on Rule2 if the consequent of Rule2, or the negation of the consequent of Rule2, is an antecedent of Rule1. Level 0 consists of all rules whose antecedents are input facts. Each level that follows consists of those rules whose left hand sides depend only on rules at the preceding levels.

The rules from the above example are divided into three levels. Level 0 contains R1,R2,R3,R6, and R7. Level 1 contains R4 and R8. Level 2 contains R5. Note that R5 is placed at level 2 because it depends on rules at level 1 as well as rules at level 0.

The second step consists of computing labels and checking these labels for redundancies and inconsistencies. It is easier to test the reduced theory for these anomalies because it explicitly states the dependencies between the input set and the conclusions.

The check for inconsistencies can be performed at each step of rule label development. The check consists of two tests: the subset/superset test and the union test. The subset/superset test checks, for any hypothesis that conflicts with the hypothesis of the rule, the partial label of the rule's hypothesis for a subset or superset of the partial label of the conflicting hypothesis. The union test computes the union of every environment of the partial label of the rule's hypothesis with every environment of the partial label of each conflicting hypothesis. An environment is a set of premises under which a hypothesis holds. The union is examined for potential contradictions.

The check for redundant rules can be performed for a level once the labels for all rules within that level are computed. The check consists of considering the contribution of each rule in the final hypothesis with respect to the given level. If some rule has a unique contribution in the label of its conclusion and defines an environment which is also generated by another rule, it is classified as redundant.

The labels for the example are developed as follows.

Level 0:
LabelR1 = {N2 ∧ N3}   LabelN4 = {(N2 ∧ N3)}
Subset/Superset and Union tests: no contradiction

LabelR2 = {N2}   LabelN10 = {(N2)}
Subset/Superset and Union tests: no contradiction

LabelR3 = {N18}   LabelN11 = {(N18)}
Subset/Superset and Union tests: no contradiction

LabelR6 = {N2}   Label¬N13 = {(N2)}
Subset/Superset and Union tests: no contradiction

LabelR7 = {N2}   Label¬N11 = {(N2)}
Subset/Superset and Union tests: union of Label¬N11 and LabelN11
is {(N2 ∧ N18)} indicating potential contradiction between N2 and N18

Redundant test: no redundancy

Level 1:
LabelR4 = {N2 ∧ N18}   LabelN4 = {(N2 ∧ N3) ∨ (N2 ∧ N18)}
Subset/Superset and Union tests: no contradiction

LabelR8 = {N2 ∧ N3}   LabelN4 = {(N2 ∧ N3) ∨ (N2 ∧ N18) ∨ (N2 ∧ N3)}
Subset/Superset and Union tests: no contradiction

Redundant test: R8 is redundant, it has unique contribution in the label of N4 and defines an environment (N2 ∧ N3) also generated by R1

Level 2:
LabelR5 = {(N2 ∧ N3 ∧ N18) ∨ (N2 ∧ N18)}
LabelN13 = {(N2 ∧ N3 ∧ N18) ∨ (N2 ∧ N18)}
Subset/Superset and Union tests: again, potential contradiction between N2 and N18

Redundant test: no redundancy

The user is notified that a potential contradiction between N2 and N18 has been detected and that R8 is redundant. The user is responsible for revising the KB-theory in order to get rid of the anomalies.

CTMS TECHNIQUE

KB verification consists of translating the KB-theory into a CTMS-theory, generating the stable extension of the CTMS-theory, computing the grounded stable extension, and testing the grounded stable extension for circular, redundant, and inconsistent rules.

A CTMS-theory is defined as (SB, R) where SB is a set of beliefs and R is a set of rules. Beliefs have the form A[LV]:(T1,...,Tn)(P1,...,Pm), where A identifies the belief, LV indicates the type (T for true or P for plausible). (T1,...,Tn) is the T-set containing the true beliefs upon which A depends, and (P1,...,Pm) is the P-set containing the plausible (not known to be true) beliefs upon which A depends. Rules have the form (T1,...,Tn,Rx)()⇒Z, where T1,...,Tn are the premises of the KB-rule and Rx is the identifier of the KB-rule. Such a rule says that the conclusion, Z[T]:(T1,...,Tn,Rx)(), will be added to SB whenever Rx is satisfied.

Translation of a KB-theory into a CTMS-theory consists of translating each KB-fact into a true belief of SB, representing each KB-rule by a true belief of SB having the form R[T]:()(), representing each KB-hypothesis by a plausible belief of SB having the form H[P]:()(), and translating each KB-rule into a rule of R.

The following is an example of a KB-theory. It is the same as the example used to examine the ATMS technique but has an addition rule R9.

Facts:
N2,N3,N18.
Rules:
R1: N2∧N3⇒N4
R2: N2⇒N10
R3: N18⇒N11
R4: N18∧N10⇒N4
R5: N4∧N11⇒N13
R6: N2⇒¬N13
R7: N2⇒¬N11
R8: N10∧N3⇒N4
R9: ¬N13⇒N2.
Hypotheses:
N2,N4,N10,N11,¬N11,N13,¬N13.

Translation yields the following CTMS-theory. Note that the beliefs representing each rule and each hypothesis have been left out to save space.

SB = { N2[T]:()(), N3[T]:()(), N18[T]:()() }

R = { (N2,N3,R1)()⇒N4, (N2,R2)()⇒N10,
(N18,R3)()⇒N11, (N18,N10,R4)()⇒N4,
(N4,N11,R5)()⇒N13, (N2,R6)()⇒¬N13,
(N2,R7)()⇒¬N11, (N10,N3,R8)()⇒N4,
(¬N13,R9)()⇒N2 }

The inference process yields the following stable extension labeled SB2.

SB2 = { N2[T]:()(), N3[T]:()(), N18[T]:()(),
N4[T]:(N2,N3,R1)(), N10[T]:(N2,R2)(),
N11[T]:(N18,R3)(), ¬N13[T]:(N2,R6)(),
¬N11[T]:(N2,R7)(), CN11[P]:(N11,¬N11)(CN11),
N4[T]:(N18,N10,R4)(), N13[P]:(N4,N11,R5)(CN11),
N4[T]:(N10,N3,R8)(), N2[T]:(¬N13,R9)() }

The stable extension shows how conclusions inferred depend upon their immediate predecessors. For verification we need to know the input data sets upon which these conclusions depend and the rules that contributed to their inference. This information is implicitly contained in the stable extension. The new extension that results is called the grounded stable extension. Each T-set contains only the identifiers of beliefs representing input data. The SB2 stable extension yields the following grounded stable extension labeled SB2[G].

SB2[G] = { N2[T]:()(), N3[T]:()(), N18[T]:()(),
N4[T]:(N2,N3,R1)(), N10[T]:(N2,R2)(),
N11[T]:(N18,R3)(), ¬N13[T]:(N2,R6)(),
¬N11[T]:(N2,R7)(), N2[T]:(N2,R6,R9)(),
CN11[P]:(N18,N2,R3,R7)(CN11),
N4[T]:(N18,N2,R2,R4)(),
N4[T]:(N2,N3,R2,R8)(),
N13[P]:(N2,N3,N18,R1,R3,R5)(CN11)
N13[P]:(N2,N3,N18,R2,R4,R5)(CN11),
N13[p]:(N2,N3,N18,R2,R3,R5)(CN11) }

The final step is to check for circular, redundant, and inconsistent rules.

The test for circular rules consists of checking the grounded stable extension for beliefs whose identifiers are also elements of their T-sets. The test found N2[T]:(N2,R6,R9)(), therefore R6 and R9 form a circular chain.

The test for redundant rules is applied to sets of beliefs with the same identifier. If two or more of these beliefs have identical data-parts, then their rule parts are checked for redundant rules. A rule is considered redundant if it has a unique contribution to the inference of its conclusion. The test found N4[T]:(N2,N3,R1)(), N4[T]:(N18,N2,R2,R4)(), and N4[T]:(N2,N3,R2,R8)(). The first and third have identical data parts and R8 is not in the T-set of any other belief, therefore R8 is redundant.

The test for inconsistent rules is built into the inference process. Contradictions detected during the inference process are represented by the corresponding beliefs in the grounded stable extension. The test found the CN11[P]:(N18,N2,R3,R7)(CN11) contradiction.

The user is notified of the detected structural errors. After revision of the KB-theory, the process must be repeated to ensure the removal of the anomalies.

CONCLUSION

Analysis of the illustrations, presented in the two previous sections, leads to the conclusion that the CTMS technique has several advantages over the ATMS technique.

The CTMS technique detects circular rules, one of the most common errors, while the ATMS technique does not. Detection of contradictions in the CTMS technique is simply built into the inference process which is handled by the TMS. And finally, the CTMS technique requires much less computation to detect the errors in the KB.

The on-site collection of data during astronomical observations is a sophisticated task, requiring instrumentation operators to simultaneously oversee a variety of complicated operations Additionally, it is desirable to perform real-time processing to produce feedback that allows astronomers to optimize the quality of incoming data These duties are frequently compounded by non-trivial computer interfaces and environmental factors unique to observatories - such as high altitude - which degrade human functioning

To increase the efficiency and quality of *in situ* data collection, the author developed a graphical interface which presents a simple interface between computer and astronomer This technique significantly reduces task complexity, program input and output is organized and presented in an easily assimilated fashion A successful observational run utilizing this interface at the NASA IRTF (on comet Hale-Bopp) is described

BACKGROUND

This paper describes cometary data reduction issues, software developed by Mumma et al and by this author, and its use in observations of comet Hale-Bopp at the NASA IRTF

Infrared astronomy has grown with the advent of digital sensor arrays Driven by constant developments in CCD technology, it continues to be a fertile source of new data Comets produce infrared light largely through flouresence as a result of incident solar energy (Weaver) This light is useful in identifying the many compounds, including organic molecules, found in these bodies (Mumma)

Data collected by IR (infrared) instrumentation is "raw" and requires reduction before it is useful, the increasing resolution of modern sensor arrays produces complex data and requires a greater degree of sophistication from the computer systems used for data reduction

IR data collection begins when photons emitted from an object of interest, such as a comet, are focused on to a CCD array Typically, the light beam is filtered before reaching the CCD array so that specific frequency bands may be studied If spectrographic data are desired, a diffraction grating may also be used to produce a continuum (such as that produced with a glass prism in visible light) instead of a spatially accurate, recognizable representation Because sources can often be dim - particularly if strong filters are used - long exposures are necessary Unfortunately, technological limitations of CCDs preclude lengthy exposures (Young) Instead, several exposures are made and summed in order to generate a single bright data set Often it is necessary to take more than one of these summed sets and add them together for even more brightness Once an adequate signal is achieved, undesirable features, such as interference from the earth's atmosphere, must be subtracted from the data set In order to accomplish this, an image is collected of the sky near, but not on, the object of interest The intensity of data and sky images are then subtracted, pixel by pixel The residual is light from the desired object

Even after this process of additive amplification, more processing is required because of "hot pixels" introduced by cosmic ray hits, thermal shot noise, and other random events

(NASA IRTF) Calibration images, called flat fields and dark fields, are used to compensate for this kind of signal noise, and are used in a similar manner to the sky images in the removal of spurious and unwanted signals Still more signal distortions, such as nonlinearities in the light beam projected upon the CCD chip, complicate the reduction process further

When all of the physical properties of the data collecting apparatus (telescope and CCD camera) have been corrected for, the data must be quantified, i e a micron or wavenumber scale fitted to it so that it is possible to identify specific features Last but not least, a data set must be able to undergo whatever operations are specified by a scientists's particular investigative regimen

Observatories maintain hardware that can provide raw images, but all data reduction is the responsibility of the astronomer, who typically employs computer software for the task This often takes place long after the data is collected, which can cause bad data or data collection errors to be hidden until it's too late to correct It is therefore desirable to have a software tool that quickly produces a spectrogram from raw data

THE EXISTING METHOD

Software to accomplish all of the above-mentioned data reduction tasks does exist and is currently in use (Mumma et al) Written in IDL, the Interactive Data Language (Research Systems), it produces useable spectrograms, although a number of issues make it impossible to use under observational conditions

The software consists of a separate program for each task The components must be run sequentially with no guidance from the software, so operator error is likely Code module names and command line syntax must be memorized Because the code was written with no overarching design principle or guidelines, the interpreter's symbol space quickly becomes cluttered with global variables, resulting in overflows

The creation of a crude spectrogram with this software consists of the steps shown in table 1 The average time needed for an operator to complete each task is also shown in table 1 The first item, creation of an initialization file, must be performed by hand with a text editor or entered line by line into the initialization module during run-time Each part of the data (eight files) and several floating point values must be individually specified Initialization file interpretation is fragile, and a misplaced space or character will cause a crash If the initialization strings are entered during initialization module run-time, a single data entry error can cause a crash, invalidating any data already entered

Thousands of keystrokes are required for the completion of this process Fully reduced data would require about an hour for each data set, as many as one hundred sets or more may be produced during a single session Clearly, it is not possible to spend hundreds of hours reducing data given only a few days at the observatory In addition, the symptoms of hypoxia caused by the high elevation of observatories and the complexity/time demands of operating the data collection hardware prevent astronomers from producing even a handful of representative spectrograms using these methods

Table 1 Task analysis of crude spectrogram production with existing software

Create initialization file	15 minutes
Run initialization module	1 minute
Run file loader	1 minute
Run minimal processing module	2 minutes
Display data	1 minute
Total time required	20 minutes

The IRTF provides a software tool ("Viewfits") which provides the functionality needed for the production of some crude spectrograms However, in addition to requiring several time-consuming steps, this tool performs integer arithmetic and produces erroneous, possibly misleading results

QUICKLOOK - A NEW APPROACH

New software, named "quicklook," was designed in an effort to overcome the

BEST COPY AVAILABLE

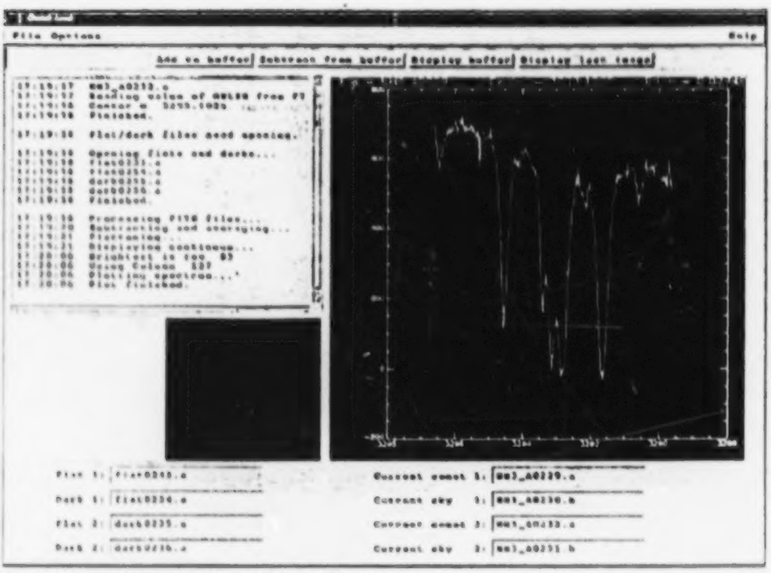

Figure 1. A spectrum displayed in "Quicklook."

difficulties described above. Quicklook is a monolithic entity; there is only one code block to run. It does not utilize a command-line interface as did the previous software, but has a graphical interface created in Interactive Data Language. Keystrokes are minimal or nonexistent because the operator can use a mouse to select input. When sequential operations must exist, all inappropriate controls are inactivated via blocking calls. Unless an operator choice is imperative, the software proceeds automatically to the next step of the reduction process. Time stamped logs of all actions are displayed in a text widget (upper left of figure 1) and saved to a date-marked file.

File commands are intuitive, using the same file menu and open commands with which most users are already familiar. It is only necessary to select the first of a series of data files; the other seven components are intelligently chosen without operator intervention. This is done by comparing filename stems and index numbers; a file called NH3_001 a will be followed by files named NH3_002 b, NH3_003 b, NH3_004 a... File type checking is performed, and if a file is missing or of improper type, an error dialog is generated and the program returns control to the user. Constants used for calculation or display purposes, such as the central wavenumber, are automatically read from data file headers.

Once the user has initiated file selection, quicklook performs all of the calculations necessary to produce a crude spectrum, pausing only to display a continuum so that the user may choose the area of interest which will become a spectrum. The spectrum is then displayed in the large window to the right with a wavenumber scale (right-hand side, figure 1). If the mouse is used to select a particular feature, that feature's wavenumber is identified and printed in the display. The spectrum and continuum can be added to or subtracted from an image buffer using the image calculator buttons above the text and spectral windows. All data products can be saved to disk for later use.

If a user wishes to make unprecedented use of data within quicklook, a shell option is available. When the shell option is selected from the options menu, quicklook exports all spectral information into variables within an IDL shell window and prints a short descriptive message explaining the name, type, and purpose of each variable. Any IDL command may be used to manipulate the data without changing the state of the current quicklook session, which can be resumed at any time.

In a best-case situation, an operator provides only three mouse clicks and zero keystrokes for the creation of a spectrogram. The entire process takes about one minute. Even a worst-case scenario results in only a few tens of keystrokes and mouse clicks,

BEST COPY AVAILABLE

stretching spectrum production time to about 2 minutes.

RESULTS

Significant reductions in task complexity and an increase in processing speed were achieved through the application of human factor and object-oriented concepts.

This software has the potential to revolutionize spectral data collection, as it is now possible to quickly and easily produce high-quality spectrograms during observations. Quicklook may supercede some or all of the intensive analysis tasks now reserved for the existing software.

HIERARCHICAL PLANNING WITH DEFINITE CLAUSE GRAMMARS

Tarik Vance-Harris

Department of Computer Science
Xavier University of Louisiana
New Orleans, LA. 70125

Faculty Advisor:

R. Raymond Lang

INTRODUCTION

Previous work in artificial intelligence (AI) has applied planning techniques to natural language generation[Appelt:85]. However, tools and techniques associated with natural language generation have not been applied to planning problems. This research demonstrates that bounded definite clause grammars may be used to solve planning problems. Specifically explored is the relationship between hierarchical task networks (HTNs) used for planning and definite clause grammars (DCGs) used for natural language generation.

The definite clause grammar used for this work is part of the `Joseph` system, described in "A Formal Model for Simple Narratives" [Lang:97]. The `Joseph` system produces natural language stories based on Russian folktales. The hierarchical planner employed for this work is an implementation of the UMCP (Universal Method Composition Planner) technique described by Erol, et al [Erol:94]. This work shows two things: (1) the conditions under which hierarchical planning and generation with a definite clause grammar are equivalent, and (2) demonstrates an implementation strategy for hierarchical planning. To demonstrate that HTNs and DCGs are equivalent under certain conditions, a set of HTN methods are transformed into rules for a definite clause grammar. The algorithm for this mapping is described in "A Formal Model for Simple Narratives." To demonstrate the correctness of this mapping, this work uses the resulting grammar to produce the same plan as produced by a hierarchical planner.

DEFINITE CLAUSE GRAMMARS FOR NATURAL LANGUAGE GENERATION

Artificial Intelligence researchers have long sought to determine the characteristics of connected natural language text. Story modeling falls into two categories: declarative and procedural. The former describes stories by pinpointing their general structure. The latter models and recreates the process used by human authors; procedural modeling then asserts that a story is anything yielded by the recreated process.

THE JOSEPH SYSTEM

The story modeling system being used in this work is the `Joseph` system [Lang:97], a declarative story generation system based on a grammar for narratives. Grammars in general describe lists of things called terminals. For example a grammar for real constants describes lists of digits, decimal points, arithmetic operators, etc. The grammar will then tell what arrangement of symbols are real constants and which are not. `Joseph` is a declarative story generation system built around a formal grammar that governs lists of events and facts. The events and facts are the terminals in the grammar. The non-terminals are high-level and intermediate components of stories such as `setting`, `episode`, `reaction`, and `outcome`. The grammar rules describe which sequences of events are stories and which are not. Figure 1 illustrates the major components of the `Joseph` system.

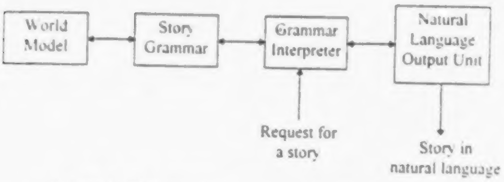

Figure 1: The `Joseph` story generation system

For example, the `Joseph` grammar rule for a `story` specifies that it consists of a `setting` followed by `episodes`:

```
Story --> Setting, Episodes
```

The system works by generating a list of events and facts, expressed as first-order predicate calculus terms. This list is referred to as the "event list." The system also maintains a parse tree of this list as it's building it. Once the event list and parse tree are finished, both of these are sent to a natural language output unit which translates these formal structures into surface text (i.e. language in a form that people actually communicate in). During the process of constructing the event list, the `Joseph` system invokes a world model which describes the events that can happen, the effects that are possible, the reactions characters have, and the goals that characters can pursue.

Below is an example of a story generated by `Joseph` along with the corresponding parse tree and list:

```
once upon a time there lived a peasant.

one day it happened that farmer evicted cat.  when this
happened,peasant felt pity for the cat.  in response, peasant
sneaked food to the cat.  farmer punished peasant.

Tree:
story(setting([p(lives(peasant))]),
  episodes([
    ep(ev(evict(farmer, cat)),
       emot(pity(for(cat))),
       act_resp(a(sneak(food, to(cat))),
                ef(punished(peasant, farmer))),
       outcm(punished(peasant, farmer))])]).

List:
 holds(lives(peasant)),
 occurs(evict(farmer, cat)),
 holds(feels(peasant, pity(for(cat)))),
 occurs(do(peasant, sneak(food, to(cat)))),
 holds(punished(peasant, farmer)),
 holds(punished(peasant, farmer))]
```

The list is a sequence of expressions which describes the story above. The first element of the list states that there lives a peasant which is the protagonist of the story. The second element states that the farmer evicts the cat. The third element of the list states that the peasant feels pity for the cat. The fourth element states that the peasant sneaks food to the cat and the fifth element states that the farmer punishes the peasant for sneaking food for the cat.

HTN PLANNING

This formalism expresses plans in the form of Hierarchical Task Networks. Hierarchical planning as described by Erol, et al [Erol:94] is made up of three types of tasks: goal tasks, primitive tasks, and compound tasks. Goal tasks are properties that an agent wishes to

BEST COPY AVAILABLE

make true in the world. These tasks are denoted as `achieve[l]`, where `l` is some state we wish to make true. Primitive tasks are directly achieved by executing a corresponding action. The notation for primitive tasks is $do[f(x_1, \ldots, x_k)]$, where `f` is an element of `F`, a finite set of primitive tasks symbols and $x_1, \ldots, x_k$ are terms. Compound tasks contain one or more goal tasks or primitive tasks. These are denoted as $perform[t(x_1, \ldots, x_k)]$, where t is an element of T a finite set of compound task symbols, and $x_1, \ldots, x_k$ are terms.

Compound tasks are much more complicated than the other two tasks. These tasks are a representation of a desired change cannot be represented as a primitive task or a goal task. Take for example the compound task of "preparing a picnic," which is different from the goal task of "having a picnic", since going to the park and eating would achieve the goal task but not the compound task.

The granularity of the domain dictates what counts as a primitive task. For example, a domain lacking a single action for "pick up something", might include actions such as "open hand," "grab cup," "close hand," and "pick up a cup," as a compound task.

Non-primitive tasks are goal tasks and compound tasks collectively. Tasks associate with each other through task networks, which can represent ordering constraints among the component tasks in the network as well as other constraints. Task networks are denoted as $[(n_1 : \alpha_1) \ldots (n_m : \alpha_m), \phi]$, where each α_i is a task, and n_i is an element of N, an infinite set of labels and ϕ is a boolean formula consisting of variable binding constraints, temporal ordering constraints, and truth constraints.

A method (α, d) associates a non-primitive task α, with a task network `d` specifying one way of achieving α. Take, for example, a method representing the non-primitive task "change a flat tire" with a task network specifying the steps involved in changing a tire, i.e., getting the new tire out, jacking the car up, etc. and the constraints among these steps, such as taking the nuts off before taking the flat tire off, etc.

Here is an example of a plan to change a flat tire. The granularity of a planning domain is arbitrary. In this example, jacking up the car is represented as a primitive, but it could also be represented as a compound act.

```
CHANGING A FLAT TIRE
1. Jack the car up.
2. Loosen the nuts.
3. Take the nuts off the tire.
4. Take the flat tire off.
5. Place new tire on the car.
6. Put nuts on the new tire.
7. Tighten nuts on the tire.
8. Jack the car down.
```

An example of a method (α, d) where α = `perform[change_tire(C,N,F,E)]` and `d` is shown below:

$$
\begin{array}{ll}
(& (n_1\texttt{: do[raise(C)]}), \\
 & (n_2\texttt{: perform[loosen(N,F)]}), \\
 & (n_3\texttt{: perform[remove(N,F)]}), \\
 & (n_4\texttt{: do[remove(F)]}), \\
 & (n_5\texttt{: perform[put\_on(E,C)]}), \\
 & (n_6\texttt{: perform[put\_on(N,E)]}), \\
 & (n_7\texttt{: perform[tighten(N,E)]}), \\
 & (n_8\texttt{: do[lower(C)]}), \\
 & (n_1 \prec n_2) \wedge (n_2 \prec n_3) \wedge (n_3 \prec n_4) \wedge (n_4 \prec n_5) \wedge \\
 & \quad (n_5 \prec n_6) \wedge (n_6 \prec n_7) \wedge (n_7 \prec n_8) \wedge \\
 & \quad (\texttt{car(C)}, n_1) \wedge (\texttt{nuts(N)}, n_2) \wedge \\
 & \quad (\texttt{flat\_tire(F)}, n_2) \wedge (\texttt{new\_tire(E)}, n_5)).
\end{array}
$$

Shown above is an example of a method to change a flat tire and shown its corresponding task network. The left hand side α is the compound task `perform(s(`$x_1, \ldots, x_k$`))`. The right hand side of the rule is the task network. In the task network each primitive task is denoted by the construct `do`, whereas each compound task is denoted by the construct `perform`.

PLANNING DOMAIN

A planning domain is a pair `(Op, Me)`, where `Op` is a list of operators and `Me` is a list of methods. A planning problem, `P` is a triple `(d, I, D)`, where `d` is the task network, `I` is the initial state, and `D` is the planning domain. In other words, the planning domain `D` holds all truths and facts about the world state, `I` is the initial state within `D`, and `d` are the steps which will solve the planning problem `P`.

SIMILARITIES BETWEEN HTN PLANNING AND THE JOSEPH SYSTEM

HTN Planning and the `Joseph` System both attempt to find sequences of events that fit some sort of criteria. The `Joseph` System generates an event sequence that must fit the characteristics of a story when translated to natural language. This means the story has to be coherent, events must happen in the proper sequence, etc. HTN planning attempts to find a sequence of steps which will cause some state to be true after all steps are completed. Because both formalisms search for sequences of actions, one can be mapped to the other. A story grammar can be translated into a set of planning methods and then loaded into a planner to generate a story structure. In a similar fashion planning methods can be translated into grammar rules and then loaded into a grammar interpreter to find a plan.

PROGRESS TO DATE

At this stage a set of set of prolog predicates have been developed which will decompose a planning method and then reconstruct the parts into a grammar rule, and also decompose a grammar rule and reconstruct the parts into a planning method. Shown below is the top level clause for this conversion program:

```
convert(M,R):-
     alpha(M,A),
     task_net(M,T),
     rule_lhs(R,A),
     rule_rhs(R,T).
```

This clause will convert a method `M` into a rule `R`. The subgoal `alpha(M,A)` extracts the α from the planning method `M`; the subgoal `task_net(M,T)` extracts the task network from `M`. The subgoals `rule_lhs(R,A)` and `rule_rhs(R,T)` reassemble these components into a grammar rule. Below is the definite grammar rule that results when the conversion procedure is run on the change tire method shown above:

```
change_tire(C,N,F,E) --->
     [raise(C)],
     loosen(N,F),
     remove(N,F),
     [remove(F)],
     put_on(E,C),
     put_on(N,E),
     tighten(N,E),
     [lower(C)],
     {prec(n1,n2), prec(n2,n3), prec(n3,n4), prec(n4,n5),
      prec(n5,n6), prec(n6,n7), prec(n7,n8),
      holds(car(C), n1), holds(nuts(N), n2),
      holds(flat_tire(F), n2), holds(new_tire(E), n5)}.
```

CONCLUSIONS AND FUTURE WORK

Future work will consist of taking the output of converting a set of methods into a grammar, and then testing the grammar as a way of finding a plan. The next stage of the work will do the reverse: converting a story grammar into a set of planning methods and using a planner to generate a story structure. When this is complete, it will show that hierarchical planning and definite clause grammar generation are isomorphic.

This work explores the similarities between hierarchical planning and generation by a definite clause grammar. Implemented is a conversion between planning methods and definite clause grammar rules using the results shown by Lang [Lang:97]. This conversion allows the use of a grammar interpreter to find plans and a planner to generate story structures. Being able to convert between formalisms allows builders of practical systems to choose from among a wider variety of implementation strategies.

Algorithm Animation:
Programming On The World Wide Web Using Java

Stephanie Hitchcock

Computer Science Department
Furman University
1800 Poinsett Highway
Greenville, SC

Faculty Advisor:

Dr. Kevin Treu

INTRODUCTION

Algorithm animation allows users to grasp the concept of a program visually in a step-by-step format, rather than relying on a textual explanation. Specifically, it is the process of building abstract models of a program by ignoring inessential features, and creating graphical views of those abstractions (Stasko 1990).

There are numerous applications of algorithm animation. Rather than debugging a program line by line, which can become tedious, an error is much easier to spot if the algorithm is animated and presented to the programmer in real-time simulation (Diacakis). It can also be used as an educational tool. Individual student interaction with an animated algorithm or visual demonstration in a classroom using such an algorithm is likely to increase the depth of understanding of the algorithm for students (Jones and Morgan). Using animation, the user is able to interact with the program as it progresses through the algorithm, rather than a chalk board or transparency method of drawing and erasing steps.

In this project, animated sorting algorithm programs were designed using the Java language. Java allows interaction over the World Wide Web. Using these programs, students in remote locations are able to interactively learn how the algorithms work. The end user does not need a Java compiler, simply a Java enabled web browser. This approach enables many new possibilities for creative teaching and learning methods and the spread of information.

BACKGROUND

Reference to algorithm animation can be traced as far back as 1966 from discussion in Brown and Sedgewick's paper "A System for Algorithm Animation" (London and Duisberg 1985). Since computer programs are difficult to understand in algorithm pseudocode, one might try to explain a program visually. For example, an instructor can draw the before and after effects of a sorting algorithm, representing snapshots of the process. The sequence of snapshots does not portray the dynamic aspects of the process being explained, however. Another problem with this method is that the steps may be confusing and it may be hard to relate the different snapshots. It is clear that the values are exchanged, seeing the values physically swapped is considerably more effective (Citrin and Gurka 1996). Software and movies are also available, which show dynamic presentations. They are expensive and time consuming to produce, however, so other methods began to be developed in order to better explain algorithms visually. Animated graphical views of a program are useful because they help the user understand programs, examine and compare existing programs, and develop new programs.

Different frameworks have been developed for algorithm animation. Tango, developed by John T. Stasko, is a system for "transition-based animation generation", based on the framework (1990). Instead of taking many days or weeks, new animations can be created in a few hours. This system is also useful for programmers to grasp a better understanding of programs by displaying them in an animated graphical way.

Since 1983, visual programming environments such as Balsa and Balsa-II have been used in introductory programming classes as teaching aids (Brown 1988). In order to emphasize small examples with more detail and to create smooth transitions between graphical images, SmallTalk, an object oriented approach, was developed in 1985 (London and Duisberg). Recently, the World Wide Web has expanded the possibilities of algorithm animation. The use of the web has branched from simple read-only applications to taking orders, and now, to running remote applications and simulations (Ibrahim 1995). Programming languages have advanced as well during the changes in frameworks.

By the early 1990's programmers began to see the limitations of C++ (Fifth 1996). A group of researchers headed by James Gosling at Sun Microsoft Systems in Mountain View, CA, worked on a project to design advanced software for a wide variety of networked devices and embedded systems (Winslow and Hammer). C++ was not designed for this type of networking project, so the research team developed the oak language, later renamed Java. The web browser HotJava was made available to the public in April 1995, and the Java Developers Kit in January 1996. An object oriented language, Java is a breakthrough for web use because it allows interaction between the user and web pages. Java is also a portable language. As a platform-independent language, anyone with a Java enabled browser can run a Java program on their computer. The language itself is simple, safe, and secure. This creates many opportunities for animation, specifically algorithm animation as a learning device, over the web.

Another framework model for algorithm animation called Mocha was developed by Baker, Cruz, Liotta, and Tamassia for providing algorithm animation over the Web. Mocha has a client-server architecture that separates the software components of a typical algorithm animation system. It also leverages the power of the Java language, which distributes interactive platform-independent multimedia applications across the web (Baker et al 1995). Other models, X Window and HotJava browser, have code protection and accessibility problems which Mocha is able to overcome. Users with limited computer resources are able to access computer animations with both HotJava and Mocha. Therefore, the end user does not have access to the algorithm code (Baker et al 1995). This breakthrough was big for the Java language, because access to these programs now requires minimal cost to the end user. Since the interactive applications are embedded in HTML documents, this enables transmission of code to the user machine, where the program can then be executed.

RESULTS

When beginning research to decide which algorithms to study and implement, sorting algorithms were found to be the best for starting this animation project. Sorting algorithms are simple in terms of code, but understanding them visually can become complex. Therefore, animation can enhance teaching, and increase comprehension on the part of students(Citrin and Gurka 1996; Jones and Morgan).

For this research, a Power Macintosh computer and the Java Developers Kit 1.0 (JDK) were used for displaying the animated algorithms. The algorithms considered thus far in this project are bubble sort, insertion sort, selection sort, and Quicksort. All of the sorting algorithms attempt to arrange elements in an array or list in increasing order. This work has shown that algorithm animation is able to demonstrate very clearly that some methods are much more efficient than others.

The most straightforward sorting algorithm is the bubble sort. Each element in an array is examined and compared to the next element on the right. If the element to the right is smaller, then the two elements are exchanged. When all the elements in the array are examined and compared in this manner, the largest element is moved to the far right end of the array. The process begins again on the left and continues until it is certain that all the elements have been "bubbled" as far to the right of the array as they belong.

The next algorithm used in this project is the insertion sort, one of the more commonly used sorting algorithms. The insertion sort divides an array into a series of sublists and sorts by comparing elements of one sublist to the elements in the sublist to its left. Starting at the element second from the left end of the array, elements are examined one at a time. The larger elements shift to the right which makes room for the element compared to be inserted in the correct sorted position.

Two other common sorting algorithms are the selection sort and Quicksort algorithms. Although the selection sort operates similarly to the bubble sort, it usually requires more comparisons but fewer exchanges of elements. Again, multiple comparisons are made down the array. First time through the array, the smallest element is located and placed at the far right most place in the array. The element that was there is exchanged with the smallest elements' original slot. The process is repeated for the second smallest element and continues till the array is sorted.

Quicksort is the most frequently used sorting algorithm. It is a recursive algorithm which chooses an element from the list, then uses that element to divide the list into two sublists. All of the elements less than or equal to the chosen element are placed in one sublist; while all the elements larger than the chosen element are placed in the other sublist. Then the same strategy is applied to the sublists recursively, until all the sorting is competed. This will be when all the sublists have only a single element or are empty.

Using HTML, the Java applets were incorporated into web pages for viewer interaction. The user is able to either jump straight from an array of unordered integers to the sorted array, or view the individual comparison and swap steps. Running several algorithms at the same time allows a user to compare and contrast them. Figure 1 shows multiple algorithms running on one screen. The programs are coded to count the number of comparisons and the number of swaps. Algorithms with the fewest number of comparisons and the fewest number of swaps are the most efficient. Using this tool, an observer is easily able to confirm the well-known theoretical facts about the sorting algorithms. For instance, Quicksort is significantly more efficient than all of the others. Users are able to do multiple comparisons of the algorithms with different random number sets, very quickly and effectively.

Displayed textually, it can be very difficult for the reader to visualize and understand the mechanics of the algorithms described above. The animated forms of the algorithms are much more user friendly and increase understanding of the programs (Citrin and Gurka 1996). Bubble sort, the most straightforward of the four algorithms, does not demonstrate time efficiency. This is the result of comparisons made through the array multiple times before sorted. Selection sort demonstrates the same efficiency as bubblesort. Theory suggests more comparisons will be made but significantly fewer exchanges. This algorithm returns the same number of comparisons and swaps in both algorithms. The differences in step-by-step comparisons can be viewed on a separate HTML page. Insertion sort demonstrated greater efficiency than the above two algorithms, both in number of comparisons and number of swaps. Fewer comparisons are needed since sublists are used for sorting. It is much easier to see the differences in efficiency between the Quicksort and the previous three algorithms. Quicksort uses a recursive method, thus doing fewer comparisons down the array. The number of swaps in significantly lower as well.

FUTURE WORK

In addition to making improvements on the sorting algorithm problem, my research is continuing with an effort to animate solutions to the well known bin packing problem and to animate a simulation of memory management in a recursive algorithm. In the bin packing problem n objects are given which have to be placed in bins of equal capacity. The objective is to determine the fewest number of bins needed to accommodate all n objects. Therefore, all individual objects must fit completely in a bin, not partially in one bin and partially in another. Many solutions can be devised for this problem. Some possible solutions to animate and compare efficiencies are first fit, best fit, first fit decreasing, and best fit decreasing. In all of these solutions the arrays are sorted first then arranged in bins. First fit sorts the objects so they are considered in order of increasing size. The algorithm places each object on the first bin in which it fits. Best fit also sorts the objects in order of increasing size. Then each object is placed in a bin which is most full among those bins in which the object fits. First fit decreasing and best fit decreasing are the same as first fit and best fit except the objects are sorted first in nonincreasing order.

First fit decreasing and best fit decreasing obtain greater efficiency by packing the objects into a fewer number of bins than first fit and best fit. I plan to demonstrate this by showing these algorithms visually on a web page using Java. This allows the user to compare the different methods and provide a choice to view a step by step packing or to view the before and after results. Again, explaining algorithms in text form can be very confusing.

Algorithm animation for bin packing will allow the viewer to walk through the results one object movement at a time and compare the different solutions for a more in-depth understanding of the algorithm.

CONCLUSION

Algorithm animation on the web is an increasingly useful pedagogical tool for teachers and students. Other methods previously and presently used such as chalkboard, overhead, simply drawing the algorithm designs, and software designed for animation, thus far have had their own specific limitations. The learner loses the linking between steps when algorithms are explained by drawings with the chalkboard and overhead. Although software such as Tango, Balsa I and Balsa II overcome this previous problem, their limitations compared to Java are that software to run the program is needed. Java is able to be created and compiled on one computer, then put on the World Wide Web for users who do not have or need a Java compiler on their computer. All the user needs is a Java enabled web browser such as Netscape 3.0. The algorithms were used in this research to demonstrate the ease of Java algorithm animation. As shown with the sorting algorithms, the user is able to compare multiple algorithms "at work" on one screen. This was never possible before with the blackboard methods. Future work with bin packing and recursive algorithms will further demonstrate that algorithm animation programs written in Java are an effective device for understanding algorithms.

INTRODUCTION

One of the distinguishing characteristics of modern software development is a very high degree of complexity. The problem domains for which such software is designed are typically much more difficult to fully understand and analyze than was the norm a few decades ago. It is not a gross exaggeration to say that we have long since automated the solutions to the most straightforward problems, and are now seeking to extend the computer's range to more subtle, richer, and more dynamic problem domains. The complexity that is characteristic of modern software efforts far exceeds an individual developer's ability to manage, and software development is now almost always a team effort. Software products containing tens or even hundreds of thousands of lines of code are not uncommon.

How then can such complex projects be managed? Can the complexity of software be reduced? Unfortunately, the answer appears to be no. Complexity is apparently an inherent or essential property of large software systems. We can attempt to manage this complexity but we cannot make it disappear. And given the difficulties that we typically encounter in attempting to produce robust, reliable software products on time and within budget, it is fair to say that we have much to learn about this difficult process.

For more than twenty years, it has been recognized by software developers that a development process involving several fairly distinct phases would be a useful, even essential, approach for large software systems. This multi-phase process is often referred to as the software life cycle. Today, there are several popular models of the phased development process, but most are modifications of the so-called waterfall model. In this model, the development process is conceived as basically a sequential process, moving through at least four relatively distinct phases from the first feasibility study for the development of a system to the delivery and maintenance of a working system

Software reliability is one of the most challenging aspects of software development, and formal methods helps to increase that reliability by using rigorously defined requirements. Formal methods involve the use of techniques from logic and discrete mathematics in the specification, design, construction, and verification of computer systems and software (NASA Guidebook II, p. 4). In the software development life cycle, requirements analysis and specification is the first step, followed by design, implementation, testing, and finally maintenance and operation. Formal methods helps to reduce the errors in the early stages of the life cycle instead of finding them in the testing phase, which can be quite costly.

The project reported on here was performed at NASA's Jet Propulsion Laboratory in Pasadena, California during the summer of 1996. The purpose of the project was to explore the usefulness of formal methods in analyzing the requirements and design of the Attitude Control System subsystem for NASA's Deep-Space 1 spacecraft. Particularly, the goal was to see if formal methods could be helpful in reducing hazardous loss of attitude knowledge. A formal specification tool called Software Cost Reduction (SCR) was used to check the existing specification. It was concluded that the SCR tool may not have been the most appropriate tool for the particular type of specification involved in the ACS subsystem. However, plans call for the continued use of the SCR tool to check other developing and existing specifications.

DESCRIPTION OF RESEARCH

The project involved analyzing the Attitude Control System for the Deep-Space 1 spacecraft, which is part of the New Millennium project. The work was based entirely on the ACS state-transition shown in Figure 1. The project began with some research on the entire system by looking at documents and papers from previous spacecraft in order to get a general idea of how it works. The ACS state-transition diagram then served as a high-level roadmap for organizing research into the lower-level details of the system. While researching the system, any inconsistencies were noted between the diagram and other available information. Some possible inconsistencies were found and noted, but at times there was insufficient information to give a solid background. Because of this, there was a question as to whether the possible problems found were truly going to pose a problem, or if they had been accounted for at a lower level. Using the events and the information that was found, work was begun with the SCR (Software Cost Reduction) tool.

SCR is a formal requirements specification tool. The toolset has many features, including a specification editor for building and displaying the requirements specification, a simulator to symbolically execute the specifications, and a formal analysis tool for testing selected properties [Heitmeyer, et. al. p. 109]. The tool is still in the development phase, and only a partial guidebook has been written to accompany it.

The SCR interface consists of tables into which the user enters information. Five general dictionaries are available for use with every specification, and the user is free to make more of his or her own dictionaries for clarification purposes. A mode class in SCR is a state machine whose states are called modes and whose transitions are instigated by events [Heitmeyer, et. al., p. 111]. For this project, three mode classes were declared, one for each major group on the ACS diagram.

Using SCR, the three mode classes were first declared as well as one mode for each of the states that are shown on the ACS diagram. Then a variable table was used and variables were created for each of the events that caused a transition from one state to another. After entering all the appropriate information and checking the specification, it was found that the initial approach was not going to work well with the tool. According to the ACS transition diagram, the ACS will be in only one state at any given time. The way it had been declared, there must be a defined state for every mode class, meaning that it would have to be in three states at any given time, one for each class. This problem was resolved by declaring an Inactive state for each class to account for when that particular mode class is not being activated. Finally, mode transition tables were written for each of the mode classes, using the variables that had been declared.

RESULTS

After all the information had been entered, the SCR Consistency Checker was used to check the tables for any errors. A few things were adjusted in the specification, but finally the checker ran without producing any errors. At this point the simulator was run. Using the simulator, a list of pending events was entered. In this case, each event was either a command from the Remote Agent to the system, or an autonomous event. SCR then used these events to simulate what would happen, and the simulation worked as planned.

It was verified that the diagram appeared to be consistent, but the tool did not provide the kind of information that had been hoped to be discovered. It may be because the SCR tool was not the most appropriate tool to use for this type of specification. SCR was designed for defining requirements, rather than checking existing specifications, like the Attitude Control System. Also, the ACS diagram is a very "flat" diagram and does not exhibit a hierarchical structure. Because of this, the tool can not be expected to generate large numbers of inconsistencies that would not be noticed just by examining the diagram. The possible inconsistencies that were noted from the background research were not accounted for in the tool so nothing new was learned from that standpoint.

What was gained was a better understanding of both the SCR tool itself and the formal methods process in general. The work that was done on SCR will be shown to the ACS domain experts because it gives a different view into the system and how it works, and hence may provide some valuable additional insights into the system's behavior. Also, the SCR tool is still being developed and many features had not yet been implemented. A report was done on the work and the problems that were encountered, which may help the developers of the tool realize some of the problems that are occurring.

DIRECTIONS FOR FUTURE RESEARCH

This work could be continued in several different ways. One way would be to develop a fault tree analysis, a method that "uses Boolean logic to describe the combinations of individual faults that can constitute a hazardous event" (Leveson, p. 317). For each of the faults that could occur in the Attitude Control System a fault tree would be designed to trace the fault back to the source. This method can work very well with software also, as it can "identify safety-critical interfaces and potentially hazardous software behavior" (Leveson, p. 323). Another direction for future work would be to develop different models for comparisons. One of these models could be a SPIN model, another type of model checker that exhaustively explores every aspect of a particular state machine. Another direction would be to develop models of other DS-1 subsystems to check for consistencies in the flight rules. An additional check could be done by modeling the ACS state-transition diagram in another specification tool and comparing it to the results from SCR.

The author's work on formal methods will be continued at Furman University. This work will involve learning and using the formal specification language tool PVS (Prototype Verification System), developed at SRI, International (Owre, et. al.). Using PVS, additional control systems will be modeled, with the goal of comparing the use of PVS and SCR as specification verification tools for control systems.

ACKNOWLEDGMENTS

The project reported on here was conducted while the author was supported by a California Institute of Technology Summer Undergraduate Research Fellowship (SURF). The author thanks Cal Tech and the Jet Propulsion Laboratory for making this opportunity available. Special thanks are due Dr. John Kelly, the Jet Propulsion Laboratory sponsor of this research project, for organizing the project and providing the opportunity to work at JPL for the summer of 1996. The author also thanks Dr. Robyn Lutz of NASA who helped propose the project and provide guidance, and Dr. Ken Abernethy of Furman University, for his help and assistance in providing the opportunity to participate in the SURF program. Finally, thanks to the many others at NASA who provided assistance when it was needed: Steve Easterbrook, Martin Feather, David Gilliam, Chan Choi, and Bruce Labaw.

A major limitation thwarting high parallel speedups is interprocessor communication. The communication limit can be particularly severe when the problems being solved involve sparse matrices. By coupling the processes of assembling and solving systems of equations (derived from either the finite element or finite difference methods), it is possible to reduce significantly the amount of information that needs to be communicated relative to the standard parallel solution methods. A new parallel language called the Recursive Substructuring Language (RSL) has been developed to implement a recursive substructuring method for solving sparse matrix systems in a distributed parallel processing environment. RSL permits the user to define the parallel hierarchical assembly and solution steps required for recursive substructuring. After discussing the implementation of RSL, empirical results will be presented showing the significant improvements in parallel speedups RSL achieves over more traditional methods for sparse matrices. The application of RSL to our work on a global atmospheric model [*Porter, et. al.*, 1996] will also be discussed.

INTRODUCTION

The parallel solution of sparse matrices has traditionally been a bottleneck in programs that use such stategies as the finite element [*Butler*, 1982] or finite difference [*Press, et. al.*, 1992] method. Approaches generally involve some kind of round-robin algorithm for the forward substitution and a serial back-substitution. The author previously explored a strategy whereby solution of sparse matrices arising in a global atmospheric circulation model was accomplished by exploiting the large granularity of the matrices [*Huneycut*,1996; *Porter, et. al.*, 1996]. Although a speedup of 3.7 over the serial solution was achieved, the method required that the entire solution vector be passed every time step, so a fundamentally parallel strategy was sought. Recursive Substructuring, described by *Bruff* [1997] as a separate paper in this conference, offers such a strategy. Recursive Substructuring Language (RSL) is a language that facilitates the description of the Recursive Substructuring algorithm. Designed to meet three specific goals and implemented using the powerful utilities Lex, Yacc, and PVM, RSL provides this interface.

Recursive Substructuring couples the assembly and solution processes used to solve systems of equations. It is particularly advantageous for parallel solution of sparse systems, because each variable is coupled to relatively few other variables. In Recursive Subtructuring a group of coupled equations (termed an element) can be assembled and solved independently from other groups of equations, eliminating all but the shared boundaries between elements. Then the reduced equations may be assembled into a larger system.

RECURSIVE SUBSTRUCTURING LANGUAGE (RSL)

In developing RSL, there were three main goals. First a language was needed that described the process defined by the Recursive Substructuring algorithm. The language also had to be parallel, that is, it had to allow for the distribution of the algorithm across multiple processors. Finally the language had to have a formal syntax description.

The first goal required that RSL be capable of describing the following objects and operations. The basic objects on which RSL needs to work are matrices. Two types of matrix structures are used, elements and super elements. Elements are primitives in the language and are provided by the user. Super elements are formed from elements and/or other super elements by a user-defined elimination/assembly hierarchy. The RSL must allow the user to describe the operations for creating this hierarchy. In addition to defining the assembly process, the RSL must provide the capability for the user to describe the mapping used in the elimination/assembly process. Mappings define which degrees of freedom are treated as internal or external at each stage of the process. One final feature of the language is the ability to specify the boundary conditions used in the solution. Solution proceeds from the top down through the hierarchy, using the user-specified boundary conditions. Internal degrees of freedom at the highest level of the hierarchy are solved and passed down the chain permitting all internal degrees of freedom to be solved.

The second requirement of the language was that it be parallel. The strength of the Recursive Substructuring algorithm is that it is inherently parallel. Each super-element can be solved independently of any others once the external solutions are known, and once those solutions are known, the super-element's constituent elements can be solved independently, etc. The process stops when the base condition is reached, i.e., the solution process yields an element which is not a super-element. To build this parallelism into the language, directives were included which group the instructions into tasks that can be executed on separate hosts. Send and receive directives to pass the super-elements and solutions around were also included.

The third and final goal in the designing of RSL was not only to code an interpreter for a language that would accomplish the previous two goals but also to develop a formal specification for the language. In this case, a formal specification is a grammar corresponding to the language that is developed in such a way to be powerful enough to meet the goals of the language and simple enough to avoid complex coding. In general the more context-sensitive a grammar is, the more power the associated language has, while the languages derived from context-free grammars are more straight-forward to program. The balance of power and ease of programming in the case of RSL was achieved by dividing the grammar into both context-free and context-sensitive parts. The organization of the tokens, or semantics, of the language corresponds to the context-free portion of the grammar, and the order of characters in the tokens, or syntax, corresponds to the context-sensitive portion. As will be shown later, this division maps onto the utilities lex and yacc quite conveniently, and eases the programming of a compiler for RSL. Having a formal specification for the language also makes the task of maintaining the language easier. Any changes made to the grammar can be easily applied to the code. Furthermore the grammar specification serves as documentation of the code. The context-free portion of the grammar is included below. The symbols in all caps signify non-terminals, lowercase signifies terminals, and underlined signifies a directive or reserved word.

RESULTS

RSL was implemented using the UNIX utilities Lex and Yacc. Lex is a programming tool that makes writing a lexical analyzer more straight-forward. As the file containing the text to be analyzed is read, Lex, using a "program" containing regular expressions and C code, tries to match each string in the input with the regular expressions. If Lex finds a string that matches one of the regular expressions, then the C code corresponding to that expression is executed. By itself, this utility is quite powerful, but in conjunction with another tool, Yacc (which stands for "Yet Another Compiler Compiler"), it gains more power still. Yacc receives inputs from a lexical analyzer, typically Lex, and using a grammar described by the user with a Yacc "program," determines if they are in the language corresponding to the grammar.

The RSL compiler maps the structure of RSL described above directly onto the functions of lex and yacc. Yacc's role in the process is two-fold; it checks the semantics by applying the production rules to the tokens as lex returns them, and it calls the proper library function when a statement (a directive and all the directive's arguments) is parsed. Lex and yacc are able to communicate because yacc calls the function, yylex, which does the actual lexical analysis and returns the token value of the string that was read, which yacc can then look up to determine the actual token. While lex can easily search for the reserved directives and determine their token values, the non-reserved strings in the language are not so easily determined because the context must be determined. In order to accomplish this task, a state diagram was developed for each statement with a context-sensitive syntax. In a state diagram each state has explicit "directions" for moving from that state to another state given an input symbol. Thus it is possible to ensure that a particular state is only reached if a specific set of inputs is given. Using this reasoning a set of states were developed that disambiguate occurrences of symbols that could belong to multiple tokens. If an otherwise ambiguous input is read, the state provides clarification. Lex provides a state dependent model to translate a regular expression to a corresponding segment of C code. For instance, an integer can occur in an RSL program in a few places. It might represent the external degrees of freedom in an assemble statement, or it might be the total degrees of freedom of the element specified in the element statement. The way lex distinguishes between these two cases is that if it reads the reserved word element, it enters the state ELEMENTSTATE, and in the case of the assemble statement, lex would be in the state EXTDOFSTATE if the number read is the external degrees of freedom.

Lex and Yacc also provide separation of the program and the language. Instead of all-purpose functions that are responsible for reading from the file, parsing the language, and then calling the library routines, with lex and yacc a set of interface functions, called by yacc when a statement is parsed, manipulate the data provided through the language and then call the appropriate Recursive Substructuring library function. For example, once an element statement has been parsed, yacc calls ParsedElement() and sends as parameters the element name, input file names, and degrees of freedom. ParsedElement() then reads in the data stored in the file and calls the appropriate library routines to create a new element. This structure is nice for a few reasons. A different language could be used, and the interface functions would still work as long as all the parameters were defined. Another feature of this structure is that since the lexical analysis is separate from the parsing which is separate from the interface functions, the language can be modified, either by adding new reserved words or changing the grammar slightly, or the Recursive Substructuring library can be modified, and the changes are confined to only that component.

Parallel Virtual Machine (PVM) was also used to develop RSL. PVM is a message passing library developed at Oak Ridge National Laboratories and available as public domain software. PVM allows for message passing across multiple architectures. Although the PVM library contains many functions for parallel computing tasks, only the send and receive functions were required. As described above, it is necessary to send and receive the assembled super-elements and send and receive the solution. The reserved words passelement, receiveelement, passsolution, and receivesolution are included in the language to provide this functionality. For example, if a passelement statement is parsed, then yacc calls the function ParsedPassElement(), which bundles up the element to be sent, and then calls the PVM routines to send the bundle to the appropriate host.

CONCLUSIONS

The Recursive Substructuring Language has been created to provide an efficient means to implement Recursive Substructuring. RSL provides the user with the capability to define an arbitrary assembly/solution hierarchy for a parallel PVM-based architecture. RSL can easily be ported to any PVM-based architecture and used for parallel solutions of sparse matrix systems. The language allows the user to set up the problem solution on multiple processors in an intuitive way.

RSL was used to study the parallel solution of sparse matrix systems, and tests conducted on the Recursive Substructuring algorithm using RSL show a linear parallel speedup is achieved as more processors are added to a problem. With 8 processors working, only a 2% decrease in speed from the expected factor of 8 speedup was detected. Because of the high degree of parallel speedups shown by RSL, a new goal of the global atmospheric circulation model project will be to use Recursive Substructuring for the solution processes.

Parallel solution, based upon explicit method, was used to study the solution of a 1-dimensional unsteady heat transfer model problem on the NASA MasPar MP-1. All processing elements (PEs) were made to exchange data using a nowrap single-step nearest-neighbor communication scheme. The results of this solution were compared to those of a benchmark, the serial Crank-Nicolson method. Both methods required time-marching. For parallel solution, all PEs were used so that each PE was at a step in the spatial dimension of one of the problem domains. That required some adjustment of time steps to ensure stability. The Crank-Nicolson method is unconditionally stable, but each time level required a solution of a tridiagonal linear system represented with 3 vectors and solved with the cyclic doubling technique.

THE PHYSICAL PROBLEM

The equation chosen for this study was a *parabolic* partial differential equation

$$\frac{\partial u}{\partial t} - \frac{4}{\pi^2}\frac{\partial^2 u}{\partial x^2} = 0, \quad for \;\; 0 < x <, 0 < t, \tag{1}$$

having the conditions

$$u(0,t) = u(4,t) = 0, \;\; 0 < t; \tag{2}$$

$$u(x,0) = \sin\frac{\pi}{4}x(1 + 2\cos\frac{\pi}{4}x), \;\; 0 \le x \le 4. \tag{3}$$

Eqn(2) was the boundary condition because it gave the values of the dependent variable, u, at the end points of the spatial domain, [0, 4], while eqn(3) was the initial condition as it gave the values of u at the beginning of time, 0. A *parabolic* partial differential equation often arises as a model of a system experiencing an unsteady state change of some quantity, u, which is commonly the *concentration* of, say, some gas, as in a system undergoing unsteady state gas diffusion, or *temperature* as in a system with transient heat transfer. In this work, the *parabolic* partial differential equation was regarded in the context of transient heat transfer in some engineering system.

The analytical solution of eqn(1), having the stated initial and boundary conditions, was determined to be

$$u(x,t) = e^{-t}\sin\frac{\pi}{2}x + e^{-t/4}\sin\frac{\pi}{4}x, \quad 0 \le x \le 4. \tag{4}$$

PROBLEM APPROXIMATION FOR NUMERICAL SOLUTION

In order to obtain a numerical solution of eqn(1), both the spatial and time domains were partitioned into discrete uniform intervals of Δx and Δt respectively. Next, the spatial partial derivative in eqn(1) was replaced with the *centered* finite difference quotient

$$\left.\frac{\partial^2 u}{\partial x^2}\right|_{x=x_i, t=t_j} = \frac{u_{i+1}^j - 2u_i^j + u_{i-1}^j}{(\Delta x)^2} + O((\Delta x)^2), \tag{5}$$

the time partial derivative was replaced with the *forward* finite difference quotient

$$\left.\frac{\partial u}{\partial t}\right|_{x=x_i, t=t_j} = \frac{u_i^{j+1} - u_i^j}{(\Delta t)} + O(\Delta x)^2, \tag{6}$$

where $O((\Delta x)^2)$, and $O(\Delta t)$ represented the truncation errors introduced by the respective replacement. In the above equations, as is elsewhere in this paper, a ***superscription*** signifies a time level while a ***subscription*** indicates a location in the spatial domain at which the value of the dependent variable, u, was considered. Carrying out the indicated replacements and simplifying the resulting equation, we obtained an approximation of eqn(1) to be

$$u_i^{j+1} = u_i^j(1 - 2\xi) + \xi(u_{i-1}^j + u_{i+1}^j). \tag{7}$$

where

$$\xi = \frac{1}{\pi^2}\frac{\Delta t}{(\Delta x)^2}. \tag{8}$$

In this study, eqn(7) was solved by both ***explicit*** and ***implicit*** methods, and the results of the solution compared to those obtained from the analytical solution, eqn(4). The explicit solution required that the condition

$$0 < \xi \leq 0.5 \tag{9}$$

be observed for the ***stability*** purpose (Burden, 1988), and (Gerald, 1996). The ***implicit*** solution required no such condition. THE SUPERCOMPUTER

Information concerning the architecture and software environments of MP-1 are well documented in (MPL, 1993), (MPPE, 1991), and (MPML, 1991). The information on the architecture, software supports, and the programming environments of MP-1 the understanding of which were essential for the successful completion of this study are well documented in in (MPL, 1993), (MPPE, 1991), and (MPML, 1991).

NUMERICAL SOLUTION

The solution of eqn(7) was obtained by both ***sequential*** and ***parallel*** methods all of which were based on the explicit solution techniques. The sequential method, whose algorithm is not shown, simply computed eqn(7) at each interior grid point of the partitioned spatial domain. Both the *sequential* and *parallel* solutions involved time-marching which began at *time* = 0 level up to the time level at which the equilibrium solution of the dependent variable was reached.

```
STEP 1: Choose an integer, $n$, and partition interval of $x$, $[0,4]$, into $n$ equal parts each of
            length$\Delta x$, and represent the interior points, $1, \cdots, N$ (where $N = n - 1$)
            with $PE_0, \cdots, PE_{N-1}$.
STEP 2: Declare the plural variables, old_u, new_u, lbc, and rbc:
            plural double old_u, new_u, lbc, rbc;
STEP 3: Declare and initialize the singular variable, time:
            float time = 0.0;
STEP 4: Choose $\Delta t$, and with $\Delta x$ of step 1, compute $\xi$ using eqn(8).
STEP 5: Hold $\Delta x$, $\Delta t$, $\xi$ and $\pi$ in double parameters delta_x, delta_t, z and pi respectively.
STEP 6: Compute the boundary values from eqn(2), and hold them in the plural variables,
            rbc and lbc:
            lbc = rbc = 0;
STEP 7: Compute (in parallel) the initial values using eqn(3) for each active PE with index i
            proc[i].new_u = sin(pi/4.0) * (1.0 + 2.0 * cos(pi/4.0 * iproc * δ_x));
STEP 8: Print out time and new_u.
STEP 9: For all active PEs DO
        Step 9.1: Update time and old_u:
            time += delta_t;   old_u = new_u;
        Step 9.2: Compute new_u using eqn(7):
            new_u = old_u * (1.0 - 2 * z) + z * (xnetW[1].old_u + xnetE[1].old_u);
        Step 9.3: Print out time and new_u.
STEP 10 UNTIL equilibrium u is reached.
```

Figure 1: Parallel Algorithm

The *Crank-Nicolson* solution was used as a benchmark to test both the accuracy and efficiency of the *explicit* parallel and sequential solutions. The *Crank – Nicolson* solution method, which is naturally both *implicit* and *sequential*, was based on the following formulation

$$-\xi u_{i-1}^{j+1} + (2 + 2\xi)u_i^{j+1} - \xi u_{i+1}^{j+1} = \xi u_{i-1}^{j} + (2 - 2\xi)u_i^{j} + \xi u_{i-1}^{j}, \qquad (10)$$

where ξ was defined according to eqn(8).

The *Crank-Nicolson* solution approach is an *implicit* solution method because evaluation of a u value at a given spatial location, say, i, and at a time level, j+1, requires the values of u, such as u_{i+1}^{j+1}, not yet determined. This contrasts the *explicit* method (see §3) in which a value of u at any time level can be completely determined from u values from the immediate previous time level. Another difference between the two approaches is that, while the *explicit* method is always subjected to the *stability* condition such as the one given in eqn(9), the *implicit* method is not limited by any such condition, hence, the *Crank-Nicolson* method, an *implicit* solution approach, is said to be unconditionally stable. One of the disadvantages of the *Crank-Nicolson* method, however, is that it is not amenable to efficient parallel solution, hence, it is usually solved, as in this study, *sequentially*.

We implemented the *sequential* shown in figure 1 to solve the *Crank-Nicolson* formulation presented in eqn(10) above. For any given time level, j, we solved that equation for each of the N interior points resulting from partitioning of the x domain. The result was a *tridiagonal* system of linear equations, Ax = k, which was solved using the cyclic reduction method (Hockney, 1988) whose algorithm is shown in figure 3.

```
STEP 1: Declare time and set it to zero.
STEP 2: Choose $\Delta x$ and $\Delta t$ and compute $\xi$ according to eqn(8).
STEP 3: For each interior point, solve eqn(3) for initial values of u.
STEP 4: Print out time and the computed initial values.
STEP 5: Obtain the tridiagonal matrix A resulting from the Crank-Nicolson method.
STEP 6: Update time by incrementing it with $\Delta t$ value.   /* Time level No. 1 */
STEP 7: For the current time level DO
        Step 7.1: Using u values and the boundary values, compute the vector, k.
        Step 7.2: Call the cyclic reduction algorithm (figure 3) to solve the tridiagonal
                  system to obtain the solution vector, u.
        Step 7.3: Print out time and the solution vector.
        Step 7.5: Update time by incrementing it with $\Delta t$ value.
STEP 8 UNTIL equilibrium u is reached.
```

Figure 2: Algorithm for the *Crank – Nicolson* Method

```
STEP 1: Declare a four-component plural vector, p, to hold A's and k's components.
            plural double p[4];
STEP 2: Initialize p with nonzero values of A and k such that
            $a_i, b_i, c_i$, and $k_i$ are held, in that order, $p_i$ is assigned
            to $PE_{i-1}$, where $1 \le i \le N$).
STEP 3: Determine $\alpha_i$ and $\gamma_i$
STEP 4: For reduction levels $0 \le l \le \log_2(N-1)$ LOOP /* Parallel Step */
        Step 4.1: Compute $\alpha_i$ and $\gamma_i$
            $\alpha_i = -a_i/b_{i-2^{l-1}}$
            $\gamma_i = -c_i/b_{i+1}$
        Step 4.2: Compute new $a_i, b_i, c_i, k_i$
            $a_i = \alpha_i a_{i-2^{(l+1)}}$
            $c_i = \gamma_i c_{i+2^{(l+1)}}$
            $b_i = b_i + \alpha_i c_{i-2^{(l+1)}} + \gamma_i a_{i+2^{(l+1)}}$
            $k = k_i + \alpha_i k_{i-2^{(l+1)}} + \gamma_i k_{i+2^{(l+1)}}$
        Step 4.3: Update p with new values of $a, b, c, k$ computed in step 4.2
STEP 5: ENDLOOP
STEP 6: Compute the solution vector, u.
            $u = k/b$.
```

Figure 3: Algorithm for the *Cyclic Reduction*

Some of the salient features of figure 3 are noted below:

- Steps 1 and 2 are the only *serial* steps carried out by the ACU, while steps 3 to 6 are performed in *parallel* by each of the active PE.
- N four-component vectors, $p_1 \cdots, p_N$, were used as as special data structures to hold nonzero components *a*, *b*, *c*, and *k* of matrix A for rows $1, \cdots, N$ respectively. The unsubscripted *p* instead had the components of 0, 1, 0, 0. The vectors, $p_1, \cdots, p_N$ were assigned to $PE_0, \cdots, PE_{N-1}$ respectively.
- An index on a parameter is the *iproc* of the PE that the active PE is communicating with. For example, occurence of b_j in a parallel step of PE_i means that PE_i is using (by copying) the *b* component of PE_j's p vector.
- Step 3 determined the special parameters, γ and α, needed in the *cyclic reduction* scheme.
- In step 4, each PE carried out the indicated computations and updates in parallel. In this step, the maximum reduction level of $\log_{10}(N\text{-}1)$ was used with no attempt to minimize it in the manner suggested by Hockney.

THE RESULTS

One set of the numerical and the analytical solutions of the parabolic system modeled in eqn(1) is shown in tables 1 for the case $\Delta x = 0.2$, and $\Delta t = 0.01$, and in which the entry, CN, stands for results obtained from the *Crank-Nicolson* approach. Because the results from the sequential and parallel implementations of the *explicit* method (eqn5) were the same for all ξ values, only the parallel solution results are shown in the table 1. The CPU times required by the various solution mehods are given in table 2. The results of computations used in this study are summarized as follow:

1. The *explicit* solutions were reasonable approximation of the system (tables 1 and 2) only when the stability condition (eqn(9)) was satisfied. When the *stability* condition was not satisfied, the *explicit* ,methods gave very poor approximation of the system. Such poor results were indicative of instability in the solution process.
2. The *Crank-Nicolson* method took much larger time steps to reach the equilibrium values of *u* than did any of the *explicit* methods. At the fixed $\Delta x = 0.2$, the equilibrium time of about 28 could be reached by the *Crank-Nicolson* method at the fourth time level of computation (that is, with $\Delta t \approx 1$ or with $\xi \approx 10.1$), whereas, to reach the equilibrium state without offsetting stability, the maximum Δt required by any of the *explicit* methods was $\Delta t \approx 0.05$. When the *explicit* and the *Crank-Nicolson* programs were time-marched using the same Δt, the *implicit* solution was about 10 times as accurate as the solution from *explicit* methods, for all ξ values.
3. As shown in table 4, the parallel *explicit* method was a lot faster than the sequential counterpart at all ξ values. The *speedup* of the parallel solution, when compared to the sequential method, averaged 15.13 for all ξ values. When compared to the *Crank-Nicolson* method, the speeds of the *explicit* approach was even more spectacular, with the *speedup* averaging 56 for all ξ values. The speed gains of the parallel *explicit* method, was reduced to only about 3 when both the parallel method and the *Crank-Nicolson* executed at their respective maximum ξs of 0.5 and 10.12.

CONCLUSION

The parallel method proposed in this study for the solution of the one-dimensional *parabolic* system was found to be much faster than the *sequential* methods used in this study when all methods used the same ξ values and when the *stability* of the *explicit* solutions was guaranteed. Based upon speeds alone, the parallel solution is highly recommended over the other methods provided that the ξ values chosen are within the limit provided by the stability condition. If the solution of such a system must not be constrained by the stability condition, or if as few as possible number of time levels of execution are required to reach equlibrium state, then the *Crank-Nicolson* method should be preferred over the other methods including the *parallel* solution approach proposed in this study.

ACKNOWLEDGEMENT

We wish to thank Dr. John Hopps, the Provost and Senior Vice president for the Academic Affairs of Morehouse College, for his indefatigable energy and support which proved to be indispensable for the successful completion of this project, and, better yet, for his promise for more future support. We are also grateful to Dr. John Dorband of the NASA HPCC, GSFC, whose mentorship was a guiding light illuminating many a tortuous path through this project. Finally, we thank the National Science Foundation and the National Aeronautics and Space Administration for providing both the seed funding and equipment for the Morehouse HPC project.

Evolutionary Confusion:
When And How To Apply the Genetic Algorithm

Michael G. Jones

Department of Computer Science
Trinity University
715 Stadium Drive
San Antonio, Texas 78212

Faculty Advisor:

Dr. Gerald Pitts

The stochastic of the problems genetic algorithms are commonly applied to make it difficult to quantify the actual advantage of the evolutionary approach. The use of genetic algorithms is not always superior to more conventional function optimization techniques. Indeed, it is clear that genetic algorithms might sometimes be a completely infeasible solution -- useless to a specific problem domain. An important task of theoretical computer science has been to offer some characterization of the types of problems in which the application of the GA is justified – both by its ability to solve the problem and its superiority to other types of optimization methods. Unfortunately, the prodigious amount of research in this area has not yielded any clear conclusions. Researchers are primarily interested in what factors contribute to "GA hardness". A useful restatement of the question is "What sort of problems are hard for the genetic algorithm?". This paper will offer an algorithmic approach towards the answer.

BACKGROUND

There have been two general approaches taken towards classifying a problem as GA difficult or easy. On one side are those researchers who say that the greatest single indication of a problem's difficulty is the degree to which it is deceptive (Goldberg, 1987, Das and Whitely, 1991). The degree to which a search space is deceptive is the degree to which its local maxima's prove problematic. Genetic algorithms are notoriously bad at overcoming certain types of deception.

On the other hand lies the consideration of the problem's epistasis. Epistasis describes the situation where one gene pair masks or modifies the expression of another gene pair. When a chromosome's epistasis is at a high level, many genes will be dependent on each other for their expression; when at a low level, there will be few (if any) genes that are so related. If epistasis is high, the genetic algorithm will likely drift and settle on a local optima (Davidor, 1991). If epistasis is low, the population is not interrelated and the evolutionary approach offers no distinct advantage. Notice that the concern of epistasis is again essentially a concern with the problem of local maxima, the only difference being that deceptive problems are universally difficult whereas problem spaces with low epistasis aren't necessarily *problematic* for the GA -- rather, they would just be more easily tackled by standard heuristic searches.

Their must be sufficient structure in the solution space in order for a genetic algorithm to process information effectively. But solution space structure alone is not sufficient for a guarantee of a successful genetic application. It seems that both the epistasis and deceptive approaches towards quantifying GA difficulty have something to recommend them, but an complete understanding of the problem has yet to be offered.

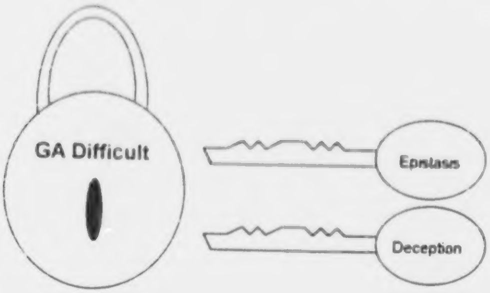

Figure 1: Genetic Algorithm Difficulty and two approaches to the quantification

A PROCEDURE FOR DETECTING GA HARDNESS

The two most important factors in detecting GA hardness are obviously deception and epistasis. And, while there is disagreement as to which factor is the most salient, a procedure can be described to detect which problems are likely to suffer from either or both of these conditions. This procedure is described below.

Phase 1: Detection of epistasis

Following Davidor, problem epistasis can be calculated by the following mathematical formula

$$\sigma_e^2 = \frac{1}{N_p} \sum_{S \in Pop} [v(S) - A(S)]^2 \qquad (1)$$

Table 1: Definitions of Symbols for Equation (1)

S	String
v(S)	Fitness
A(S)	Genetic Value
σ_e^2	Genetic Variance
N	Population Size
	Population

Phase 2: Detection of Deception

The detection of deception will involve the calculation of the order-1 hyperplanes of the solution space. Following Das and Whitely (1994) we can classify any problem as fundamentally deceptive if the globally optimum solution cannot be inferred by solving the order-1 hyperplanes. Although a discussion of hyperplane solutions is not within the scope of this paper, an excellent discussion of this topic can be found in Koza (1992), pages 33-46.

Phase 3: Synthesis and interpretation of the results.

High Level of Epistasis and or Deception:
As stated earlier, the results of the investigation of epistasis can be equivocal. High epistasis indicates that the GA will likely encounter problems with local maxima. For a problem like this, a technique involving a certain measure of random movement (like simulated annealing) would be a useful addition to the evolutionary approach.

Low Level of Epistasis:
A low level of Epistasis simply indicates the genetic algorithm offers no distinct advantage. Although it is sometimes suggested that genetic algorithms are unique in that they can be expected to optimize any function, it must be known that the GA can expect to do no better than random search over the space of all the functions in cases where epistasis is extremely high. If there are no relations between members of the population, how can the GA be expected to do any better than random search? The best alternative in this case is to use a more conventional, non-evolutionary technique such as heuristic searching.

Mid-level of epistasis and low deception:
The evolutionary approach is readily applicable and appropriate to the problem.

CONCLUSION AND FUTURE RESEARCH

This paper has outlined a simple procedure for testing the GA hardness of a problem. The most obvious next step would be to construct a computer program capable of receiving the relevant data and outputting the resulting "hardness level" of the problem. In order for this to happen, three things must come together.

(1) The two steps above must be mathematically or algorithmically formalized.
(2) An appropriate means of program input must be constructed.
(3) The program itself must be written with adequate user interface and output organization.

Input and observations on any of these three steps would be greatly appreciated.

ACKNOWLEDGEMENTS

The author wishes to thank Dr. Aaron Konstam for his gracious contribution of research materials as well as Dr. Gerald Pitts for his advice in the structure of this paper.

IRIS Explorer is a powerful visualization system with the capability to handle very large data sets. This paper discusses the need for such visualization capabilities when considering advanced modeling efforts such as the global atmospheric circulation model (GCM) recently developed by Porter et al. (1996). Computations of the temperature, pressure, density, and velocity from the GCM at potentially several hundred thousand grid points results in a vast amount of data that is too overwhelming to be interpreted merely by reading tabulations of numbers. Using IRIS Explorer, a volume visualization application was created to render interactively the atmospheric data generated by the model, displaying the results on a colored, spherical surface. To enhance the visualization, modules were developed to superimpose on the temperature or pressure display the fluid velocity vector at each grid point. As a final level of enhancement, animation and viewing with stereoscopic glasses have been developed to observe the model's predicted changes in atmospheric circulation over a time sequence of the computations. This paper discusses ways that the IRIS Explorer system can be used to develop several example visualizations. This paper will conclude by discussing how VRML was used to publish these visualizations on the World Wide Web.

INTRODUCTION

Computer aided visualization techniques are important in today's society because they allow scientific researchers to understand data through visual perception. Many data sets used by scientists today are extremely large and cannot be interpreted by merely reading tabulations of numbers. It is much less tedious and less time-consuming to view a set of data in the form of an image, whether it be a graph or an animated movie, than it is to carefully examine a large set of numbers in order to interpret its meaning. In *Visualization in Scientific Computing*, a 1987 report to NSF, the National Science Foundation, it is stated that "an estimated 50 percent of the brain's neurons are associated with vision." Therefore, the need for powerful visualization software is essential.

This research involves visualizing the results computed from a global atmospheric circulation model developed by Porter et al. (1996). The work is supported by NASA/University Joint Venture (JOVE) grant NAG8-1101 and was performed in collaboration with scientists at Goddard Space Flight center. IRIS Explorer software was used to render this visualization. This paper first focuses on the atmospheric model itself. Following that is background and explanation about the IRIS Explorer visualization system. The paper will conclude by demonstrating the results obtained with this visualization system, and discuss implications this type of research will have on the future with the advent of VRML, the Virtual Reality Modeling Language.

EXPLANATION OF THE MODEL

The model employs a decomposition of the atmospheric system. The solution is based on a spectral semi-implicit, time-marching scheme that has been optimized for a vector processing machine. Present computations are performed for a global grid consisting of the following grid points on the globe: 318 altitudes, 24 latitudes, and 8 longitudes. The variables used are pressure, density, and momentum density. Formulation of the model is described in Chan et al (1994) and a parallel version of the model by Porter et al. (1994) The main equations on which the model is based are the continuity equation (1), the momentum density equation (2), and the pressure equation (3):

$$\partial_t \rho = -\nabla \bullet \mathrm{M} \tag{1}$$

$$\partial_t \mathrm{M} = -\nabla \bullet (\mathrm{MM} / \rho) + \nabla \bullet \sigma - \nabla p - 2\Omega \times \mathrm{M} + \rho g - \rho\Omega \times (\Omega \times r) \tag{2}$$

$$\partial_t p = -\nabla \bullet (p\mathrm{M} / \rho) - (\Gamma - 1)p\nabla \bullet (\mathrm{M} / \rho) - \nabla_{ad}\Gamma(\nabla \bullet f - \varepsilon) \tag{3}$$

In the above equations, σ is the viscous stress tensor, Ω is the angular velocity of the rotating planet, Γ is the adiabatic exponent, and f is the radiative or conductive energy flux.

By applying visualization to the model we hope to understand the behavior of its five prognostic variables. The model includes important non-linear gravity wave mean flow interactions and has demonstrated that gravity waves may be the source of the observed but yet unexplained quasi-biennial oscillations.

IRIS EXPLORER

When deciding upon software for visualization, IRIS Explorer proved to be the most effective software to use in displaying the global atmospheric model. It is available for SGI computers and is a powerful visualization system with the capability to handle very large data sets. It was developed by Silicon Graphics, Inc., and is supported by the Numerical Algorithms Group (NAG). IRIS Explorer is a full featured visualization environment that is very helpful in creating applications for all fields of scientific visualization, including computational science, engineering, and many other scientific research areas. Explorer is an example of a Modular Visualization Environment, also known as MVE, which consists of a graphical user interface allowing linking of software modules with links called pipelines. Modules used in constructing applications may be either pre-built (which are included in a library of modules) or created by the user from external user-supplied code. A useful source on IRIS Explorer is the NAG website.

IRIS Explorer is built on Open Inventor, an object-oriented toolkit which assists programmers in three dimensional interactive graphics programming. Scenes are developed using Open Inventor and are viewed with a scene viewer, which may either be a walk-through viewer, examiner viewer, or fly viewer. An advantage to using IRIS Explorer applications is that they can be remotely run on any X window system that supports OpenGL.

The most fundamental parts of IRIS Explorer are the modules, as mentioned above. Each module is a tool which performs a particular task, the most common task being the manipulation of the scientific data set. Examples of functions that modules can perform are: handling data input, rendering a scene, image processing, and post-processing of data. Individual modules can each have their own user interface. This allows the user to easily change the parameters of the module using buttons or knobs called widgets. For example, a user may interactively control the color palette used to display the data. The flow of data in and out of each module is regulated by input and output ports. At these ports the user may attach the modules together with pipes in order to perform higher level tasks. A set of modules that are connected together in order to create a specific application is called an Explorer map. The function of the map depends on the functions of the modules and the way in which they are connected. A sample map is shown in Figure 1.

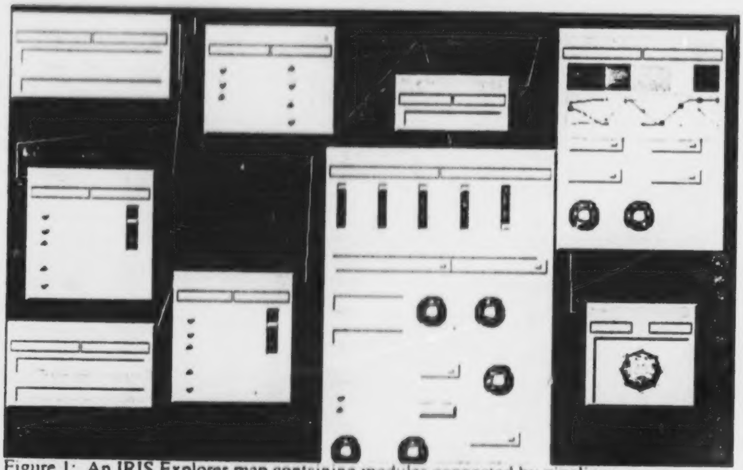

Figure 1: An IRIS Explorer map containing modules connected by pipelines.

The two basic data types provided by Explorer are the pyramid and the lattice. Both provide considerable flexibility for representing model data. The data type used in this work is the lattice, which is used to represent multi-dimensional arrays. For example, a lattice may hold the information for a three-dimensional data set with a scalar value at each point in three space, or it can represent a data set with a vector field at each point. Each coordinate point in three-dimensional space may be associated with a vector of arbitrary dimensions. The lattice is made up of several data sub-structures which serve the purpose of defining the dimensionality of the lattice data structure, and may be chosen depending on the user's needs.

BEST COPY AVAILABLE

If a module having a desired function is not already available in the module library, the user can create one with the Module Builder application. The user creates a function in C or FORTRAN and Module Builder encapsulates the function and attaches input and output ports. Once constructed, these user-defined modules can link with other existing modules. The DataScribe is a secondary application which helps to perform data conversion between Explorer data and other data formats. It has a control panel for a data conversion module, whose internal features can be changed by the user. Its main functionality is to convert a data file into a data format which can be used by Explorer. It may also be used to output an Explorer lattice into a specified file format.

MODEL VISUALIZATIONS

The fundamental means of visualization used in the rendering of the global circulation model is referred to as Volume Visualization. Explorer's render module, which is, in essence, an Open Inventor scene, incorporates volume visualization when displaying objects. The data is kept in a 3D volume buffer. Computation time is saved because the scene does not have to be scan converted each time changes are made in the viewing conditions. The 3D grid of uniform cubic volume units which represents the volume data are called voxels and are stored in the volume buffer, or a large 3D array. The volume buffer contains a voxel for each point in the 3D grid space, similar to the way a pixel and frame buffer work in two-dimensional graphics.

Volume visualization permits the user to examine an interior section of the data set: The volume buffer stores the coordinates for the complete volumetric set. Therefore, the visualization tool has easy access to these grid points. Tools that allow the user to see inside the rendered volume rather than just viewing the surface properties include slicers and segmentation tools. A slicer freezes one of the three indices in a 3D array and then displays a two-dimensional slice in terms of the other two indices so the user can see a particular slice of the volume. Segmentation tools chop the object up into separate user-defined volume sets so as to view the properties of a small portion of the volume. These two types of tools are encapsulated as modules and utilized by the IRIS Explorer system in order to make the visualization of volumetric sets simple. Stereoscopic viewing is further enhancement which enables the interpretation of three-dimensional volumetric data. The SGI Indigo 2 computer has the capability of displaying Open Inventor scene graphs in 3-D with the aid of stereoscopic viewing glasses. This enables researchers to better understand volumetric data in three space. This type of viewing is utilized in our research.

IRIS Explorer is used to render interactively the atmospheric data generated by the global circulation model. The model computes velocity vectors, pressure, temperature, and density, for every grid point on the globe. The objective is to display data in a manner that permits direct interpretation. Temperature data at each coordinate point in three-dimensional grid space is viewed in terms of color, with red being hottest and blue being coldest. Along the y-axis are 24 latitude slices, along the x-axis are 8 longitude steps, and along the z-axis are 318 altitude steps. To view this large data set an Explorer map was constructed.

The map has the following structure. First, the ASCII data file which contains atmospheric data is read in by the ReadXYZ3D Module. This module converts the ASCII data into the lattice format which may be used by Explorer for manipulation and rendering. The lattice data is then fed into a SampleCrop module which contains widgets to select how much of the full data set is to be used. For example, if a data set contains 8 nodes in the first dimension, 24 nodes in the second dimension, and 318 nodes in the third dimension, the SampleCrop module has widgets to easily assist the user in viewing only a selected portion of this data. The Orthoslice module takes a 3D data set and isolates one of the dimensions in order to display one slice of the object. The Generate Colormap Module sets the color of the model corresponding to its temperature. The color map can be selected to show the small scale variations in temperature which exist in the model. The module LatToGeom converts the lattice data type to the geometry format and prepares it to be displayed by the Render module. The Render module provides a great degree of user-interactivity. The user can zoom in and out and change the camera angle so as to see the model data from many different viewpoints.

In the above visualization application the model can be viewed as the specific set of points that make up the data set or as a set of planes. The visualization network just described will generate a rectangular style of data, because the array indices are used as the coordinate points in the 3D grid space. For greater realism, the data was mapped onto a spherical surface, resembling the surface of a planet. In order to map the data points properly onto a sphere, the spherical polar coordinates for the grid are used.

Visualization of the velocity fields is somewhat more complex. Each of the points on the sphere, in addition to a temperature value, has a corresponding three dimensional vector value which shows the fluid velocity of the atmosphere at that point. Because these vectors were read out from the model in Cartesian coordinates, they must be transformed for the correct directions on the sphere. The relevant transformations are as follows. The z-axis must be transformed to the direction of r, because for each point on the sphere z must be pointing outward to represent altitude. The x-axis must be transformed into a horizontal vector perpendicular to the direction of r which will map a latitude. And the y-axis must be transformed into a longitude. The following transformation matrix (4) was used for mapping vectors on a spherical surface. (Foley, van Dam, Freiner, and Hughes)

$$\begin{bmatrix} \frac{(z\times r)_x}{|z\times r|} & \frac{r\times(z\times r)_x}{|r\times(z\times r)|} & \frac{r_x}{|r|} & 0 \\ \frac{(z\times r)_y}{|z\times r|} & \frac{r\times(z\times r)_y}{|r\times(z\times r)|} & \frac{r_y}{|r|} & 0 \\ \frac{(z\times r)_z}{|z\times r|} & \frac{r\times(z\times r)_z}{|r\times(z\times r)|} & \frac{r_z}{|r|} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \bullet \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} = \begin{bmatrix} x' \\ y' \\ z' \\ 1 \end{bmatrix} \qquad (4)$$

A FORTRAN preprocessor was written to perform the conversions utilizing the equations derived from this matrix. The VectorMaker Module, developed by Hans Vahlenkamp and John P. Sheldon at NOAA's Geophysical Fluid Dynamics Laboratory, was located on the web and used to display vectors. The VectorMaker generates vectors with user-defined lengths, colors, and shapes. Vectors can be displayed as arrows, cones, cylinders, and fade lines. The final Explorer map developed renders both the velocity and temperature together in one visualization. In order to achieve this the two separate maps were fed into a single Render module. The images in Figure 3 show examples of results from this visualization. The shading indicates differences in temperature, and the small arrows represent the fluid velocity vectors. The left image shows a top view of the model data, showing a counter-clockwise circulation. The middle image displays the eight latitude slices to see what is occurring inside the sphere of the model. The right image shows the side view with reversals of the vector fields at different latitudes.

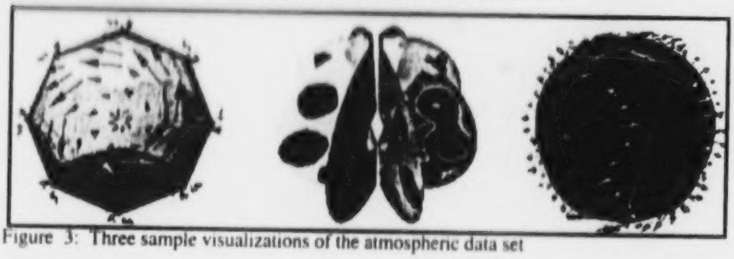

Figure 3: Three sample visualizations of the atmospheric data set

ANIMATION

The For loop is an essential module when trying to create an Explorer animation. The For loop can be attached to the Orthoslice slice number widget allowing continuous stepping in altitude. In order to emphasize the change in temperature with altitude the data at each altitude was plotted with a fixed radius. For this type of animation there is essentially a two dimensional spherical model which is displayed in terms of longitude and latitude, with each altitude slice isolated.

Another goal in this research was to animate a three dimensional data set in which the time dependence of the data at a specified longitude, latitude or altitude could be displayed. This involves using a four dimensional coordinate set with corresponding data for each coordinate using variables x, y, z (coordinates), time, and data. To handle such a four-dimensional data set, Data Scribe was used to develop the Read4DData module. Animation of an Explorer map which uses such large lattices results in a slow run-time. Therefore when running a time-step loop for every altitude, the modules fire too slowly and too sporadically to give a smooth complete animation. The map may also run slower depending on how complex the conglomeration of modules is.

There are two ways to handle the slow run-time. The first is running the modules of a single map application on different machines. Explorer has the capability to run each of the modules contained in the same map on different workstations in order to make the application more efficient. This would be a definite advantage if a map were created in which multiple tasks must be performed at the same time. But in this case, the For loop which runs our animation process depends on manipulation from each module in a sequential order, rather than many modules operating at the same time. So even though multiple machines might make a map run faster in some cases, in this case modules must wait for a task to be completed by a previous module in order to fire so no time is gained.

The other option is to save images from the Render screen and put them together as an animated movie. Two tools on SGI computers make this task an easy one. These are MovieMaker and MoviePlayer. MovieMaker is used to create movies by concatenating successive images. MovieMaker can handle many types of image formats, including tiff and SGI's rgb format. Movies are output in one of SGI's movie formats. MoviePlayer is used only to play back the SGI movies. The only problem with these tools is that it is very time consuming to save many subsequent image files from the Render module, for the model must be in the precisely correct position in order for the animation to look as if it is running smoothly. This type of animation takes up a large amount of disk space, 900 KB for each image. Therefore, a movie of several hundred frames utilizes a large amount of space.

WEB RESEARCH AND TECHNOLOGY

In carrying out the visualization the need arose for additional modules which were not already part of our module library. In some cases, researchers had already developed a module for a user's specific need, and the only problem is locating that module. Once found at a website, a module's source code could easily be downloaded and compiled for use with the Explorer system. A few helpful websites are the IRIS Explorer Repository, the NCSA PATHFINDER home page, and the physics department at the University of Illinois at Urbana-Champaign. A very helpful library of modules is located at the GFDL web site. Hans Vahlenkamp and John P. Sheldon at NOAA's Geophysical Fluid Dynamics Laboratory in Princeton, New Jersey have developed 48 modules, some of which work on our version of Explorer 2.2, others were written for Explorer 3.0.

A recent development which significantly adds to this type of scientific visualization is VRML, or the Virtual Reality Modelling Language. It allows three-dimensional objects to be rendered and interactively manipulated using World Wide Web browsers. VRML as a modeling language gives us the capability to publish the results of our research world-wide on the Internet. The final model described was saved from the Render Screen Module as an Open Inventor scene graph file. Inventor files are very similar to VRML files and they can easily be interchanged with a converter. Some sites on the Internet will perform this conversion. VRML is actually a subset of Open Inventor with extensions for handling WWW links. A VRML object is downloaded over the web as a scene description and rendering takes place locally on the users machine, which enables the user to easily fly-through the scene on their local machine. Objects within the scene can be hot- links to other VRML, HTML, or other WWW resources.

The fact that VRML has arrived as a standard for scene viewing on the Internet provides many advantages in our field of work. Since VRML viewers have been developed for many platforms, (SGI's, PC's, and Macs), no longer must scientists, researchers, and other interested parties possess the same platform for sharing and manipulating these object scenes. Before the advent of VRML, only two dimensional scanned or digital images could be published; therefore a model such as ours could be viewed as a still image, but not interacted with or manipulated by other researchers in our field of work. Now, researchers worldwide, even those who do not have access to a Silicon Graphics workstation, may view and even manipulate our visualization.

CONCLUSION

IRIS Explorer has been used to develop a 3D stereoscopic visualization of results from our global atmospheric circulation model. The visualization allows the superposition of temperature and velocity data in a detailed and illustrative manner. By extending this model it has been possible to create an animated visualization and then view the model with stereoscopic glasses in order to better understand the characteristics of the data set. As a final element of research the results of this model are being published on the World Wide Web. Though our model is presently in its primitive stages, once fully developed it may help to predict climate changes on a human time scale. The reconstruction of a planet's climate through such a model as this one will eventually help us to better understand our environment.

Experimental Evaluation and Comparisons of Algorithms for Incremental Graph Biconnectivity[*]

Ramgopal Mettu and Yuke Zhao[†]

Department of Computer Sciences
University of Texas at Austin, Austin TX 78712

Faculty Advisor:

Prof. Vijaya Ramachandran

ABSTRACT. We describe our implementation of an algorithm to maintain the connected components and the biconnected components of a graph where vertex and edge insertions are allowed. Algorithms for this problem can be applied to task decomposition in engineering design. Connected components are maintained using a disjoint set data structure and the biconnected components are maintained by a block forest. We implemented an incremental biconnectivity algorithm presented in (Westbrook and Tarjan, 92). The algorithm runs in $O(n\log n + m)$ time, which represents an amortized time of $O(\log n)$ per operation, where n is the number of vertices and m is the number of operations. However, the algorithm does not address the issue of deletions in disjoint sets, which seem to be needed in order to implement the algorithm correctly. Hence we develop the concepts of *dynamic holes* and *static holes* to support variations of the standard disjoint set structure that allow the deletion of certain elements. We present four different implementations for the maintenance of the biconnectivity, which utilize these variants of the standard disjoint set structure, and analyze their performance. We present extensive timing information for each of these implementations.

INTRODUCTION

We consider the problem of maintaining graph connectivity and biconnectivity information incrementally, i.e., where vertex and edge insertions are allowed. Algorithms for this problem can be applied to task decomposition in engineering design. Here we specify an implementation design that uses the algorithm presented in (Westbrook and Tarjan, 92) which runs in $O(n\log n + m)$ time, where n is the number of vertices and m is the number of operations. In order to implement the algorithm, we found the need to delete certain elements from disjoint sets. This issue is not addressed in (Westbrook and Tarjan, 92), however. Hence we developed the concepts of *dynamic holes* and *static holes* to support variations of the standard disjoint set structure that allow the deletion of certain elements. These variants of the standard disjoint set structure are used to maintain the connected components and enables efficient block tree operations in the block forest.

Westbrook and Tarjan also describe another algorithm that uses dynamic trees to maintain the block forest, which runs in $O(m\,\alpha(m, n))$ time, where α is the inverse of Ackermann's function. For the data sets we consider, the first algorithm would likely be faster in practice due to a smaller constant factor in the running time. Hence it is the one that we describe in this paper.

Throughout this paper, n refers to the total number of vertices created; m refers to the total number of operations (*new_vertex*, *insert_edge*, and *find_block*); k refers to the total number of *find* and *merge* operations performed on disjoint sets.

DATA STRUCTURES

Disjoint Sets Structure that allows Deletions:

Disjoint sets are used to maintain both connected components and the children of nodes in the block forest in our implementation. We first present the standard disjoint set structure which supports *find* and *merge* operations (Tarjan, 75). Then we present a variation of the disjoint set data structure that allows selective deletion of elements.

A disjoint set structure is a group of x objects such that each of them is a member of exactly one set at any given time. Each set has a unique label which identifies it. Initially the x objects are in x different sets, each containing exactly one object. In order to handle set unions, we represent each disjoint set using a tree, where each node in the tree represents a distinct object. The trees are bottom-up trees, which means each node knows its parent but not its children. If a node's parent pointer points to itself, it is the root of that tree. The *find* and *merge* operations for the standard disjoint set data structure are well known and can be found in (Tarjan, 75).

In order to manipulate the children sets of nodes in our block forest, we need to both merge two sets together, as well as delete certain elements in a given set efficiently. The disjoint

Figure 1. Disjoint set structure that allows deletions, the diamonds in (ib) and (iib) are the elements in the disjoint set that represent the actual objects (ovals), via *element_ptr*

set data structure was chosen to allow fast merging. In order to quickly delete elements from the disjoint set data structure, we developed the concept of *dynamic holes*.

A *dynamic hole* is a node in the disjoint set tree structure which does not represent any element of the set. Its only purpose is to maintain the tree structure of the disjoint set. If we do not use such nodes, in order to delete an element in the disjoint set structure we would have to relink all of the children of that element, which could be a very expensive operation.

In our block tree data structure, each element in a children set is pointed to by a child node that it represents. This representation of the children sets of nodes is of crucial importance, because besides *find* and *merge*, we need to delete elements from children sets when the parent-child relationships change with *block_evert* and *block_condense* operations. This modified disjoint set data structure is maintained even when a node is removed from the set since the elements act as virtual copies of the actual nodes. It is this abstraction that makes the existence of the *dynamic holes*, and thus their future use, possible.

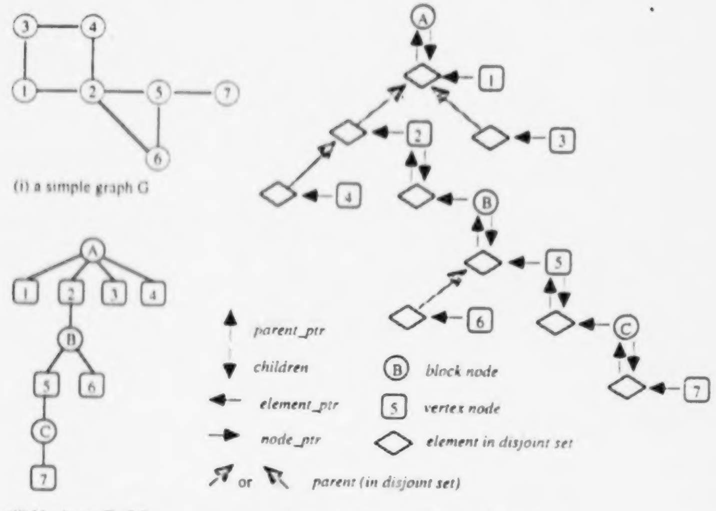
Using the above representation, we delete a child *c* from a children set of a node *v* by making *c* →*element_ptr* point elsewhere. The element in the children set of *v* that used to represent *c* is now a dynamic hole, since it no longer represents any child node of *v* (see Figure 1). We may reuse this dynamic hole when another node is to be added to the children set of *v*, so that the sizes of the disjoint sets are kept small enough to preserve the time bounds (see Lemmas 3). These dynamic holes are not removed, since they do not affect the asymptotic running time of the algorithm and their removal could be very time consuming.

In two of our implementations, we use *static holes* instead of *dynamic holes* to deal with deletions. A *static hole* is created as a singleton element to represent an empty children set in the block tree. Its need will become clear in Implementation III and IV.

Block Tree:

In order to maintain the biconnected components of a graph incrementally, we make use of a tree structure of the blocks and vertices of a connected graph called the *block tree* (Westbrook and Tarjan, 92). The collection of block trees given by the components of a graph $G = (V, E)$ is called the *block forest*. The block tree has two types of nodes: vertex (square) nodes, which represent the vertices of G; and block (round) nodes, which represent the blocks (see Figure 2). A *block* is equivalent to a biconnected component in the graph, where two vertices are in the same *biconnected component* if and only if there are two vertex disjoint paths between them or the component is a single edge. The children of the block nodes represent the vertices that are contained in that block. If a vertex belongs to more than one block, it will be the child of one block node and have the other block nodes as its children. Such a vertex is called a *cut vertex* since its removal disconnects a component into two or more components.

BEST COPY AVAILABLE 270



(i) a simple graph G

(ii) block tree T of G

(iii) representation of T in our data structure

Figure 2. Block tree data structure in Implementation I
Each block node or vertex node may have two diamonds linked to it; the diamond directly under it is the root of the disjoint set that represents its children; the one on its immediate left represents itself in the children set of its parent (i.e. the disjoint set that represents its siblings).

All terms such as *parent, child, siblings* and *grandparent* that appear hereafter refer to the relationships within the block forest, unless otherwise specified. Hence all vertex nodes have parent and children of block node type only, and vice versa; also, all siblings are of the same node type.

IMPLEMENTATIONS

We present four implementations, all of which support functions on the block tree which allow us to maintain biconnectivity incrementally. The functions allowed on the block tree are as follows:

- *block_new(u*: vertex node): create a new block for the vertex which will be the root and only element of the disjoint set representing the vertices of this block; return a pointer to the new block.
- *block_parent(u*: vertex node): access the object in the disjoint set which represents the children of the parent of *u*, traverse this object to the root of the disjoint set; access and return the parent.
- *block_find(u, v*: vertex node): given two vertices *u* and *v*, if both are in the same block return that block, return *null* otherwise.
- *block_evert(v*: vertex node): given a vertex node *v*, reroots the block tree at *v* by traversing the tree from *v* to the root, reversing parent pointers along the way. This function is called when edge is inserted between two connected components.
- *block_link(u, v*: vertex node): combine the two block trees containing *u* and *v*, where *v* is the root of the smaller tree. This function is always called after *block_evert*.
- *block_condense(u, v*: vertex node): given two vertices, condense all block nodes in the path from *u* to *v* into a single block node. This function is called when an edge is inserted within one connected component.

Implementation I: Homogeneous Block Tree with Dynamic Holes:
In this implementation we make use of the modified disjoint set structure above to maintain the children of the block tree nodes, since we have to deal with deletions in the disjoint sets. The details of this implementation are discussed in (Korupolo et al., 96). A minor difference in the current implementation with the one described in (Korupolo et al., 96) is that the *node_ptr* field in the elements of the disjoint set structure is removed.

Children sets of nodes in a block tree are maintained using the disjoint set data structure, so that merging the children of two nodes can be done in $O(1)$ time. Each node is doubly linked to its children set, that is, the node contains a pointer to the root of its children set, and that root in turn contains a pointer back to the node (see Figure 3). This implementation is labeled "homogeneous" since the children set of every node in a block tree is maintained by a disjoint set.

Implementation II: Mixed Block Tree with Dynamic Holes:

Our second implementation does not use disjoint sets to represent block nodes. At the expense of uniformity throughout the data structure, it is possible to eliminate the disjoint set representation of block nodes and use direct pointers from block nodes to their parent vertex nodes. With this change, every traversal from a block node to a vertex node is reduced to constant time instead of one pointer step. Additionally, *dynamic holes* caused by *block_condense* are eliminated. The number of *dynamic holes* is only reduced, so the asymptotic running time is the same as Implementation I.

Implementation III: Mixed Block Tree with Static Holes:

The data structure for the block tree in this implementation consists of block nodes, vertex nodes and cut-vertex nodes. The vertex nodes are organized into disjoint sets that represent children sets of different block nodes as in previous implementations. A cut-vertex node is a virtual copy of and doubly linked to its correspondent vertex node. A cut-vertex has a pointer to one of the elements in the children set of its parent block. This way its parent can be accessed while the merging of children sets of different blocks can be done efficiently. A cut-vertex node is created and deleted dynamically, while a vertex node is never deleted once it is created, instead it goes into an obsolete state when a cut-vertex node representing it exists. Block nodes, then, point to their parent cut-vertex nodes, not vertex nodes.

Cut-vertex nodes can only be created when two distinct components are linked together. When these cut-vertex nodes are created, their corresponding vertex nodes become obsolete in the data structure. For example, if u becomes a cut vertex in the graph, the corresponding vertex node in the block tree will point to the newly created cut-vertex node. From that point on, all operations which take u as an argument will use the cut-vertex node instead of the vertex node for information about u, unless u ceases to be a cut-vertex.

In the linking process, it is also possible that a new block B needs to be created between the two cut-vertices, u and v. B will be the parent of one of these cut-vertices, say u, so u must point to an element in the children set of B. Since B has no children at this point, a *static hole* is created as a singleton element to represent the empty children set of B. Then, v can be linked to this *static hole* to complete the linking process. In this implementation, we combine the *block_evert* and *block_link* operations into a single function, *block_evert&link*.

Implementation IV: A Mixed Block Tree with Static Holes and Standard Disjoint Set Data Structure

In this implementation, instead of using the disjoint set data structure that allows deletions above, we use the standard disjoint set data structure described in (Tarjan, 75). Then, instead of using an abstract representation of the elements of a disjoint set, a vertex node itself is an element of the disjoint set . This was not possible in Implementations I and II, due to the need for deletions in the disjoint set data structure. As a consequence, separate sets of functions are used to maintain the disjoint sets used for connectivity and in the block tree.

Overview:

The data structures presented above maintain graph connectivity and biconnectivity properties separately. The disjoint set structure of (Tarjan, 75) is used to maintain connectivity, while the block tree data structures above maintain biconnectivity. The function *new_vertex* creates a new vertex and a new block which contains it; *find_block* simply calls *block_find*; while *insert_edge* is defined below:

```
insert_edge(u, v: vertex):
    if u and v are in the same block, do nothing.
    otherwise if they are in the same connected component, call block_condense(u, v)
    otherwise they are in different connected components, in which case we combine the two
    block trees by calling block_evert() with the vertex in the smaller tree, and make the root of
    the resulting tree a child of the vertex in the larger tree. Then merge the two connected
    components by calling merge(find(u), find(v)).
```

ANALYSIS AND COMPARISONS

We tested our implementations on graphs with 500, 1000, 5000, 10000 and 20000 vertices, respectively. The initial graphs are very sparse (with exactly $n/2$ edges) or sparse (with exactly n edges) and are randomly generated. They are loaded using *new_vertex* and *insert_edge* operations. Ten such graphs are generated for each category, then 3 random test sequences of different sizes are run on each graph. The test sequences are uniformly mixed with 50% *insert_edge* operations and 50% *find_block* operations. The sizes of sequences are approximately $n/10$, n and $2((n\ln n)/2 - n)$, respectively. The largest sequence size was chosen as $2((n\ln n)/2 - n)$ since a random graph is very likely to become connected when the number of its edges reaches approximately $n\log n$ (Spencer, 94), after which every operation will be within one block tree. Once the block tree becomes biconnected the performance of the algorithm speeds up substantially from $\theta(n\log n + m)$ to $\theta(m\,\alpha(m, n))$ as indicated by (Westbrook and Tarjan, 92). Hence we take the length of the update/query sequence to be $n\log n/2$, minus the number of edges in the initial graph, and multiply it by two since half of the test sequence operations are *find_block* queries.

In the course of our experiments, we studied the difference in performance between

Table 1. Selected update times for Implementations I - IV

implementations with *dynamic holes* versus *static holes*. We expected that there would be fewer *static holes* than *dynamic holes*, but were not sure if the overhead of maintaining *static holes* would lead to slower performance. After running the third implementation, we found that the use of *static holes* with the modified disjoint set structure (Implementation III) led to slower performance than Implementation II, but the use of *static holes* with the standard disjoint set structure (Implementation IV) led to the best performance (see Table 1).

CONCLUSION

In this paper, we described and implemented an algorithm for the maintenance of incremental biconnectivity. The algorithm allows insertions of edges and vertices and answers biconnectivity queries, i.e., "given two vertices of a graph, are they in the same biconnected component ?" In the course of implementing the algorithm given by (Westbrook and Tarjan, 92), we discovered an issue that was not addressed in (Westbrook and Tarjan, 92): the need for deletions in disjoint sets to preserve the efficiency of the algorithm. We modified the standard disjoint set data structure and developed two new concepts in dealing with deletions: *dynamic holes* and *static holes*. We have implemented two versions of the algorithm which use *dynamic holes* and two which use *static holes*. With both *static* and *dynamic holes*, we prove that the performance of the overall block tree data structure with our disjoint set structure is still $O(n\log n + m)$, where n is the number of vertices in the graph and m is the total number of queries and updates. We tested the four implementations extensively and presented the experimental results and analysis.

ACKNOWLEDGMENTS: We would like to thank Madhukar Korupolu for the extensive discussions in the early stages of this project. This paper is part of an undergraduate honors thesis project undertaken by Ramgopal Mettu and Yuke Zhao.

Gerald N. Pitts, Ph. D.

ABSTRACT

Real-time graphics are becoming commonplace for data visualization. As a result, there is a pressing need for special effects that enhance the illusion of reality in these real-time systems. Many special effects make use of particle systems to model the desired effect, present in effects like explosion and fire. The environmental effect of wind is yet another effect that would enhance the illusion of reality in a real-time system, and can be implemented through the use of particle systems.

Making use of the Ultravision API, the authors have implemented the effect of wind using the particle-mesh method. The authors have manipulated polygons, textures, and animated particles to simulate the effect of wind on real-world objects. The authors believe that a particle-system approach produces a fluid-like simulation of wind that can affect applied to many objects in a scene.

This paper provides a comprehensive explanation of the process of implementation of a particle-based wind effect, and will explore the difficulties inherent in such an implementation. The suitability of the particle-mesh method for modelling wind has been explored and is discussed in terms of implementation in the Ultravision API for the Nintendo64. The authors also provide a breakdown of the time and resources required to implement various parts of the simulation.

INTRODUCTION

As personal computers become increasingly more powerful, applications tend to slowly take advantage of this power. However, computer games have been known to push the envelope -- to take advantage of every available resource, sometimes bypassing the entire operating system in order to maximize efficiency. Of course, with games constantly pushing the limits of machines, theses games are becoming more and more realistic and impressive.

The latest trend of computer gaming (within the last two years) has focused on games that relate to the player through a three-dimensional world. Many games have been created which are first-person combat games (i.e. Doom, Quake). If this trend continues, 3D will become the focus of many more games, much like the development and popularity of the Nintendo 64 has demonstrated.

Realism, being an important requirement of 3D games, can easily put a huge burden on the machine, causing a game to slow to a crawl. Instead, game designers must make use of methods which simulate the real world, making the game world appear more dynamic and lifelike. The use of special effects is one way to make game worlds appear more lifelike. Special effects may include things such as explosions, realistic water, or complex environmental changes.

One type of effect that proves useful in a 3D world is the simulation of natural environmental effects such as wind. Such an effect would be useful when several objects in the world need to be moved in accordance with a system that determines the defining characteristics of wind. The main problem with a wind effect is the potential algorithmic complexity of the system. Therefore, careful consideration of the algorithms used in the design is necessary.

For the purpose of making this preliminary system more available to consumer-level machines (i.e. home-based PC's as opposed to Silicon Graphic workstations, for example), the method to be discussed here will deal with wind within a 3D world, but will make use of a 2D design. In other words, the wind system will exist in a 3D world, but will only affect objects two-dimensionally. This will, of course, limit the realism of the wind system, but for the preliminary discussion of the system that is made here, it will work quite well.

In order to implement a wind system, the algorithm makes use of a particle system. A particle system is a collection of particles whose behavior is defined by an algorithm or a series of algorithms. Many times, a particle system is made up of thousands of particles, which makes particle systems useful for photorealistic rendering of objects which are difficult to model with polygons. However, in the interest of a high efficiency implementation, the use of several thousand particles will not be explored here. Instead, the system will be composed of no more than a couple hundred particles.

IMPLEMENTATION

Particles

The basic idea of a particle is that it is a single point within 3D space. The particles used in the system described here have the following characteristics:

1) Direction vector
2) Speed value
3) Current lifetime value
4) Maximum lifetime value

The direction vector is a two-dimensional variable that defines the heading of the particle in the game world. Note, however, that the direction vector is two-dimensional instead of three-dimensional. As explained earlier, the wind system is based in the three-dimensional game world but functions on a two-dimensional plane, which is equivalent to saying that the Z-coordinate location of an object does not matter when determining wind effect calculations (assuming that the positive Z-axis is pointing upwards in respect to the computer screen, with the positive X-axis to the right and the positive Y-axis pointing into the screen -- see Figure 1).

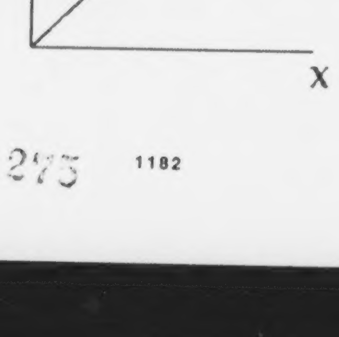

Figure 1: Assumed Axis Orientation of Game World

The speed value should be the speed of the wind particle, which is specific to a couple of things. First of all, the distance aspect of the speed value (as the *miles* portion of a miles per hour unit, for example) will depend on the definition of the game world and how the coordinate system is arranged. The time aspect of the speed value (as the *hour* portion of a miles per hour unit) should be consistent within the implementation of the wind manager (and probably consistent within the implementation of the game world itself). As a result, the time base of the speed value should be the same time base as the lifetime value so as not to create a system that requires translations between time bases in order to function properly.

The current lifetime value is the length of time that the particle has been in existence. Since this application of the wind system is in real-time (as opposed to a frame-based rendering implementation), the length of time value will not be a scalar, but will instead represent a definite increment of time (i.e. seconds, milliseconds, microseconds, etc.).

"Wind Manager"

The collection of particles is known as a particle system. In this implementation, however, a wind-specific particle system will be known as the Wind Manager. The Wind Manager controls the creation, management, and destruction of wind particles, and maintains the overall cohesion and "flow" of the wind system. The Wind Manager has four main functions, as follows:

1) Create particles.
2) Initialize a particle's parameters according to the Wind Manager's parameters for particle generation.
3) Cycle through all the existing particles and kill those whose current lifetime has exceeded their maximum lifetime.
4) Cycle through the list of "blowable" objects and perform the necessary movement routines (which are specific to each object).

Due to the fact that the Wind Manager must initialize all the particles that it creates, there are several characteristics of the Wind Manger itself that must be defined before particle initialization takes place. The necessary characteristics are as follows:

1) Particle base direction
2) Particle direction variance
3) Particle base speed
4) Particle speed variance
5) Particle base lifetime
6) Particle lifetime variance
7) Particle maximum effective distance
8) Particle maximum effective distance variance

What makes the wind system dynamic is the presence of the several variance variables that limit the range that a particle's characteristics can vary from the base characteristics of the Wind Manager. For example, a particle's speed value can be determined by the equation

$$\text{speed}_{\text{particle}} = \text{base speed} + (\text{speed variance} * \text{random number}) \qquad (1)$$

The maximum effective distance characteristic is the maximum distance that any particle can affect an object. During the time that the Wind Manager determines the closest particle to an object, the Wind Manager, upon finding the closest particle, will then make sure that the distance between the particle and the object is not larger than the maximum effective distance as specified in the characteristics of the Wind Manager.

Problems with the Current Implementation

Although this is a viable method for producing wind-like effects in a real-time system, there are several problems with the design of such a system. These problems will be presented here in order to make the reader aware of their existence.

First of all, the algorithm demands that the entire particle system be searched through in order to find the particle closest to an object that is to be affected by wind. Consider a situation in which there is a very large wind system (i.e. covers a large area of the game world) containing 2000 particles. In order to find which particle is closest to any object, the locations of all 2000 particles must be checked. This can end up to be quite time-consuming for the computer, and the time could probably be better spent than searching through massive amounts of particles.

In order to avoid such a dilemma, keep the number of particles in the wind system to a reasonable level. In a real-time computer game, there is no reason to use thousands of particles to model wind, since the user(s) of the game are unlikely to notice the difference between the use of 2000 particles and 20 particles. If designed carefully, a game can function well without overuse of run-time data.

Another potential problem with this wind system design is that every particle in the wind system must be updated regularly. The exact interval between particle updates is not important and is actually under the control of the game designer, but when updated, the entire particle system must be updated to reflect changes within the system. Updates must be performed on the current lifetime values of the particles, as well as the position. In a system of many particles, this can be very expensive (with respect to time), and if the particles are updated very frequently, the speed of the entire game can be affected.

The final major problem with this implementation of a wind system is that the wind system shown here is not at all based on meteorological fact. Therefore, the results obtained from this implementation are not at all realistic enough to pass as the focal point of any game. Instead, the implementation can be used to add variety and realism to a game that does not need realistic modeling of wind effects in order to function.

ALTERNATIVE METHODS

As with most computer-based problems, there is always more than one method that can be used to solve a problem. The implementation of a wind system is no different.

"Wind Array Approach"

One other method of creating a wind system would be to create a grid of particles over a certain area of the game world. In order to simulate wind, the Wind Manager (which is the same as Wind Manager previously described) creates the grid with all the particles having a wind strength of zero. Then, as the game begins to run and wind is called for, the Wind Manager increases the wind strength of the first row of particles according to a wind gengrating algorithm within the Wind Manager. On the frame following that, the second row of particles looks at the wind strengths of the particles in the preceding row and uses those values to find their own wind strengths, while the Wind Manager creates new values for the first row of particles again, replacing the old values. During the next frame, the third row accesses the second row's wind strength values to determine their own values, and so on. What is immediately apparent is that this causes a wave-like effect that travels through the grid of particles as time goes on. Objects, in order to be affected by wind, would find the particle nearest to itself, and use the wind strength value of that particle to determine the action that should be taken.

The main problem with an implementation of this sort is the amount of particles that would be necessary to cover an area of decent size. As the area that is to be affected increases, the number of particles present in the system will also need to be increased if the resolution of the grid of particles is to be maintained. Furthermore, since particles receive their strength values from particles preceding them by row in the grid, it can be potentially expensive to update the entire system every time a new frame of animation is needed, especially when the animation is rendered in real-time.

Non-Particle Approach

Yet another method for developing a wind system would be to avoid particles altogether. This type of system would instead use algorithms to develop the necessary wind data according to the position of each object. The Wind Manager would still be present, but would be very different indeed. During the execution of the program, the Wind Manager would iterate through its list of objects that should be affected by wind, and depending on each object's position, would develop wind strength values and directions on an individual basis. It would be up to the specific implementation as to whether the Wind Manager would provide consistent wind data to all objects in the game world or whether the wind data would be random.

Although this might be an acceptable method of simulating wind, it lacks the ability to have the wind system move through the game world, which the particle-based implementations can easily accomplish. This might be able to be overcome by using more complicated algorithms during an object's wind solution, but it also makes the implementation much harder on the programmer of the system.

CONCLUSION

Now that computers are becoming more powerful, the applications that consumers are looking for will make use of that power. This fact is readily apparent from the number of three-dimensional games that have stormed the marketplace. With this demand for more powerful games comes the demand for more realistic games which incorporate effects that mimic their real-world counterparts. These effects, such as wind, can become part of a game system that helps the environment come alive, but can also put a heavy toll on the machine, possibly hindering the flow of the game. As a result, implementations of special effects must be very efficient, allowing a decent balance between desired realism and algorithm speed (because realism and alogorithm speed are usually mutually exclusive). The algorithm presented in this paper is an attempt to create a dynamic wind system which maintains a fair amount of realism while minimizing overhead. This algorithm can stand on its own, but is better suited as the basis of other algorithms with similar goals.

Parallel Programming: A Disparate Architectures Approach

Jason Pounds

San Antonio, TX 78212-7200

Faculty Advisor:
Dr. Maurice Eggen

As computers become faster and more advanced, the applications written for them demand more from the system, taking up memory and space. If the limit on processor speed is ever approached, alternate methods of programming will need to be used. Parallel and distributed programming, where the workload of a program is distributed to one or more machines working simultaneously, is one solution to this problem.

The concept of parallel programming has grown rapidly with the development of more efficient programming languages and the availability of networked clusters of workstations. However, many networks are not comprised of machines of the same architecture; often there are workstations that may outperform the other machines due to faster processors or the nature of their architecture. This research will address working in a networked cluster of workstations of disparate architectures, and will attempt to discover the optimal method of distributing work in such an environment.

INTRODUCTION

Since the invention of computers, engineers have quested to design faster and faster computers. As our technology increases, our patience decreases, and even faster results are desired. As modern applications become more advanced, they require more memory and processor usage, consuming the time the processor can use on other applications. Many current problems, such as simulation, modeling, and computations on large amounts of data, require faster processing to allow completion of the tasks in a reasonable amount of time [5]. Will there be a point where it is no longer physically possible to make computers run any faster? Where will programmers turn if this limit is reached? A method of programming needs to be developed that will allow more efficient use of computers. Distributed and parallel processing proposes one possible solution to this dilemma.

The concept of distributed processing can best be expressed by the following analogy: a man is preparing dinner for his family. He begins by cooking the meat. Once he finishes cooking the meat, he sets that dish aside and begins cooking the potatoes. When he has finished preparing the potatoes, he sets them aside and starts on the string beans. He continues preparing dish after dish until the meal is prepared. By the time the last dish is done, however, the meat is cold. An efficient cook would have observed that the stove has four burners, and that preparing the potatoes does not depend on whether the meat has finished cooking. He thus begins the many meal-time preparation tasks simultaneously (in parallel) and attempts to schedule their start times so that they will all finish at approximately the same time. This simple example provides an intuitive idea of performing tasks in parallel. Each step of the preparation of the meal can be thought of as a task and each burner on the stove a processor. Division of problems to tasks and allocation of tasks to processors is one of the goals of parallel and distributed parallel processing. Since there are physical limits to the amount that one processor can accomplish, why not use a divide and conquer strategy? Divide the job at hand into several tasks, and allocate the tasks to processors which work simultaneously in an effort to finish the overall job faster.

This research addresses working in a networked cluster of workstations of disparate architectures, and will attempt to discover the optimal method of distributing work in such an environment. In order to best understand this environment, it will help to review some of the basic principles in parallel processing.

Parallel processing is a method of processing in which the programmer takes a serial task that lends itself to parallelization, and breaks it into subtasks that can run in parallel. In a networked environment, many workstations are linked together and messages are passed in a distributed environment. The tasks are distributed to the workstations and then are executed in parallel. Machines linked in a network do not have shared memory; data must be distributed to the different machines through message passing. Network environments are common since most people have access to a network instead of an actual multiprocessor machine. Multiprocessor machines cost a considerable sum of money, usually more than a network of simple workstations, and are not easily available to all programmers and researchers.

Using the master/slave programming paradigm, a master process sends tasks to slave processes. The master and the slave processes are able to run on one to many processors. The master process handles the input/output and setup procedures. Once it is time for actual computation, the master spawns slave processes and sends them work to do, making sure each slave receives the information it requires. Each slave in turn can proceed to spawn additional slave processes, adding to the workload on the virtual machine. When a slave finishes its computation, it passes information back to its parent, sending any data required. Once the slave process ends, its parent releases the process to allow more of the virtual machine's computation power to the remaining processes [5].

RESEARCH

This research focuses on the distribution of work in a distributed parallel processing environment where the processors in the environment are of disparate architectures. This research sets out to prove that an even distribution of work is not be the optimal workload distribution in such an environment. If any of the processors in the environment are different from the others, whether that be in speed or general architecture, the best workload distribution would likely take place in a situation where the processors that can complete the given task faster receive larger tasks than the processors that have a harder time working on the task. The testing was conducted using the quicksort algorithm, using the additional tools of PVM for parallelization.

Since the quicksort is an O(n log n) sorting algorithm, it is one of the faster sorting algorithms. The quicksort has proven to be one of the most efficient sorting algorithms because it sorts random order and reverse order files faster than most sorting algorithms. The quicksort algorithm was selected because it could be parallelized and yet was simple enough to be readable and understandable by the general audience.

Parallel Virtual Machine (PVM) is a parallel programming tool that was developed at Oak Ridge National Laboratories in 1989 and enjoys considerable usage today. Developed as a collection of C, C++, or Fortran libraries, PVM "software provides a unified framework within which parallel programs can be developed in an efficient and straightforward manner using existing hardware" [1]. PVM was selected as the parallel language because it is available in the public domain and because it had already been ported to both the SGI and HP architectures. PVM enables a group of heterogeneous machines to act like a single parallel "virtual machine." This "virtual machine" effectively acts like a single multiprocessor machine. PVM handles the message passing and data conversion between the architectures. PVM applications are written as groups of cooperating tasks. Using the resources provided by PVM, a task can send and receive data, pass information between other tasks, broadcast information to all processors, spawn new tasks on other processors, and add or remove processors from the "virtual machine" during execution; this provides both flexibility and computational power.

The "virtual machine," operating in the master/slave model, had one master process and four slave processes. One processor was assigned to each process in order to take full advantage of the processor's power. The processors spanned two different architectures, the HP and SGI, each running two different operating systems. The computers selected also had different processor speeds. All five machines run on RISC based architectures. Sinope, an HP 9000 712/60, was used as the machine spawning the master process. It has a 60 MHz processor of VLSI design, with PA-RISC architecture [2]. Calypso and Elara are used as two of the machines where slave processes were spawned. Calypso is an HP 9000 712/60, identical to Sinope. Elara is an HP 712/80, identical to Sinope and Calypso except that its processor runs at 80 MHz [2]. Nereid and Triton are SGI machines with MIPS processor chips. Nereid is an SGI Indy using a MIPS R4600, 132 MHz processor [4]. Triton is an SGI Indigo2 Extreme using a MIPS R4400, 200MHz processor [3].

The primary goal in parallel programming is to increase throughput. The programmer hopes to speed up execution time by running parts of the programs on different processors. Unfortunately, the parallel version of an algorithm is not always faster than its serial counterpart; sometimes this is due to machine concerns that do not exist in serial programming [5].

Load balancing is the process of distributing tasks in the best possible way to get the most efficient performance in parallel. This is most important when there are many tasks of various sizes to be performed. The tasks need to be distributed to the processors so that the least amount of waiting takes place when smaller tasks finish before larger ones. Large or frequent delays slow down the overall performance of the parallel algorithm [5]. The best distribution of data needed to be produced so there would be the least amount of overall waiting time during execution. To guarantee this, multiple test runs were created using different load balances between the tasks in the "virtual machine." An optimal balance point where the faster processors had more of the workload than the slower ones was sought after.

To determine the comparative speed of the processors, the program was run with 100% of the load on one processor at a time. Once the relative speeds of the machines was determined, the first test run started with each task receiving 25% of the load. After this point, work was slowly shifted from the slower processors to the faster processors, recording the overall execution time at each point. Eventually, the load reaches its best balance, and the execution time begins to lengthen with further shifting. Shifting the load slowly in this manner guarantees the optimal balance will be found.

Communication performance is involved whenever two or more machines must pass information. Increasing the number of processors being used may increase execution time depending on the bandwidth of the connections and how much information must be passed. This is especially a problem in a distributed memory environment where large data sets are passed between processors [5]. In this research, large sets of data are being passed between the master and slave processors. In order to minimize the affect of bandwidth and line noise, all the machines in the "virtual machine" were on the same Local Area Network (LAN). This minimized the distance that information would need to travel across the connecting cables, and minimized the chance that other machines were using the same cables to pass information.

Timing began with the start of the program from the command line and ran to the completion of the program. Once the test file was read into a dynamically created array, the program checked the command line arguments of the executable, and then computed the amount of data to send to each processor. Sinope then spawned four slave processes, one on each machine, and passed each process the section of the array they were sorting. Each slave process proceeded to receive the array into a new dynamic array. This new array was sorted on each machine, and then passed back to Sinope. Once Sinope received the data from all four processes, the program halted. Testing was conducted late at night during a week when the computers were not being used to attempt to minimize processor demands from external sources. Multiple test runs were created for one, two, three, and four machine "virtual machines" to get complete information about how the load shifting affected execution time. Each run was timed and run multiple times to get an average execution time for each different load balance.

TESTING RESULTS

The data file consisted of one-hundred thousand random numbers. Before test runs could begin, the relative speeds of the machines needed to be determined so the test runs could be correctly configured, shifting more of the load balance to the faster machines. First, a serial version of quicksort was run on each machine to compare to the speed of our parallel testing program. Table 1 denotes the results of the serial tests.

Table 1 Serial quicksort tested on each machine (all times in seconds)

Machine	run 1	run 2	run 3	run 4	run 5	average
Triton	37.51	37.83	37.82	37.69	37.80	37.73
Elara	43.50	42.80	42.60	42.60	42.70	42.84
Nereid	57.12	57.02	56.97	56.95	56.95	57.00
Calypso	59.80	59.70	59.70	59.70	59.70	59.72

The average time of the serial sort is faster on Elara than on Nereid; despite its faster processor, Nereid was is not able to complete the task as fast as Elara. Based on these results, Elara was given a larger load than Nereid on the virtual machine.

The testing program was then executed on each machine in the virtual machine individually by giving 100% of the load to the machine being tested, and giving 0% of the load to the remaining three machines. Theoretically, these test runs should take more time than the serial versions of the program, because the array must be passed over the network to the machine, and the same serial quicksort is used in the slave testing program. The only difference between the serial test runs and these parallel runs should be the time it takes to pass the array over the network and the time PVM takes in preparing the virtual machine. The results of this test are displayed in Table 2.

Table 2: Quicksort tested on each machine in parallel (all times in seconds)

Triton	Elara	Nereid	Calypso		run 1	run 2	run 3	run 4	run 5	average
100%	0%	0%	0%		41.5	40.8	41.2	42.1	40.9	41.30
0%	100%	0%	0%		46.1	46.4	46.5	46.7	46.5	46.44
0%	0%	100%	0%		61.0	60.7	60.7	60.8	61.0	60.84
0%	0%	0%	100%		62.8	62.4	62.4	62.4	62.3	62.46

Notice that the average execution time is slower for each machine in Table 2 than in Table 1 as predicted. On the basis of these results, the priority computer selection in the virtual machine was assigned to be Triton, Elara, Nereid, Calypso. The actual test runs began using the configuration determined in the preliminary test runs. The first test runs compared machines in pairs to compare speeds intra-architecture and cross-architecture. The following test runs compared three machines at once, and concluded with runs taking advantage of the entire virtual machine.

The most interesting aspect in all of the test runs was that, no matter which method of load shifting was used, there was always a point where the optimal load balance was reached, producing the fastest execution time in the run. Beyond this point, the execution time of the test program would increase. In addition, this point of optimal load balance was always reached very close to the starting load balance. This phenomenon is noticeable in Table 3. Notice that relatively close to the initial starting point of 25% load on each machine, the execution speed reaches an optimal speed of six seconds, and then begins to increase.

Table 3: Sample test run (all results in seconds)

Triton	Elara	Nereid	Calypso		run 1	run 2	run 3	run 4	run 5	average
25%	25%	25%	25%		7.4	6.8	6.8	6.7	6.8	6.9
27%	25%	24%	24%		6.4	6.4	6.4	6.4	6.4	6.4
29%	25%	23%	23%		6.1	6.1	6.1	6.1	6.1	6.1
31%	25%	22%	22%		6.0	6.0	6.0	6.0	6.0	6.0
33%	25%	21%	21%		6.4	6.4	6.3	6.4	6.4	6.38
35%	25%	20%	20%		6.8	6.8	6.8	6.9	6.9	6.84

To insure there is a lower bound on speed, some random test runs of extreme workload imbalance were executed. It was necessary to be certain the curve noticed in the test runs was not a wave that would reach a point of maximum speed and curve back down toward faster speeds.. All of these random tests at extreme load imbalances provided results far above the test runs closer to the starting balance.

The extreme test runs also point out that the percentage of the load on Triton is very important to the overall performance of the virtual machine. The results from the test runs on all four machines were compiled into a list based on the load on Triton. Each group of load percentages for Triton were averaged to calculate the average execution speed of the program for each percentage load on Triton. These results are displayed in Figure 1. In this figure, the execution is fastest on the average when Triton has 29% of the load. This figure also depicts the curve noticed in the individual runs, where a point of optimal balance is reached.

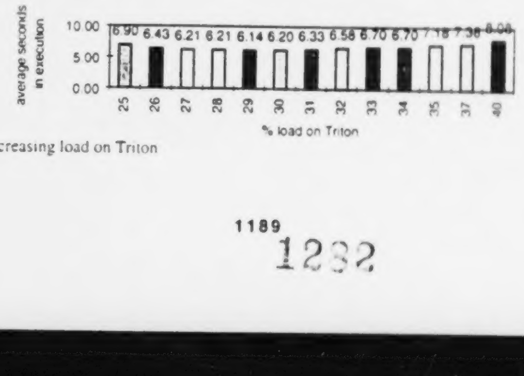

Figure 1. Increasing load on Triton

The percentage of the load given to Calypso is also very important. There is a point where the advantage of having a virtual machine is lost if one processor is not doing enough work. Figure 2 depicts this result. Notice that as less of the load is allocated to Calypso, the execution time increases. (Note: the curve jumps at 20% load on Calypso because a majority of the runs at that percentage had Triton at 35% and 40%, which, as per Figure 1, skew the data at that point.)

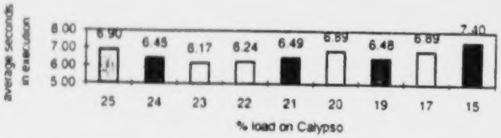

Figure 2. Decreasing load on Calypso

CONCLUSION

After examining all the results from the research, it was concluded that the hypothesis stated above was correct: A perfect load balance, where each machine received the same amount of work was not the optimum configuration. In all the test runs performed, a point was reached where at least one test run was faster than the perfect load balance run. Since the hypothesis was proven true for virtual machines of two, three and four processors, it was additionally concluded that this will be true for virtual machines with more processors, however, additional experimentation with addition processors is need. This researcher is sure there will be a point of optimal balance on a virtual machine with disparate architecture processors on any size virtual machine. On very large virtual machines this optimal balance point may not be noticeable as it could be a difference of a matter of microseconds by that point.

Distributing the load by giving more workload to faster processors indeed decreased execution time of the program overall. Program execution time decreased noticeably as more work was given to Triton and Elara in all of the test runs. It was also noticed that not all the processors always need to have more work shifted onto or off of them. For example, in Table 3, the load on Elara was left alone, and yet, an optimal balance point was still reached. This suggests that some processors may be more important to the virtual machine than others, which was noticed in Triton. The percentage of the load on Triton was important to the overall virtual machine, as depicted in Figure 1. In general, the more work shifted on Triton, the faster the overall runs performed, up to a certain point. Once Triton has too much of the workload, the virtual machine loses some of its effectiveness. This led to the conclusion that shifting the balance too far on one machine increases execution time and ruins the purpose of the parallel machine.

ABSTRACT

Developing large, complex computer programs requires capturing knowledge from multiple domain experts, customers, and end-users. A major concern is the management of this information and its use in identifying the reasons behind design and implementation decisions. Tracing, the mapping between requirements and artifacts of a software system, addresses this issue. Typically, tracing requires that all system artifacts be physically linked to the requirements, an expensive and time-consuming process.

This paper discusses an approach to tracing that does not require physical links from documents to the program code and, as a result, makes the maintenance of traceability a simpler task. The suggested tool is based on context monitoring, an approach which verifies that properties specified in the requirements are met by the program code and alerts the user when a violation occurs. The paper also discysses the issues in implementing this tool.

INTRODUCTION

When developing a large computer program, it is difficult to ensure that the program will meet its specified requirements. Software engineers must elicit a vast amount of knowledge from various domain experts. In addition, the requirements typically continue to change during the development of the program. In such a dynamic environment, it is difficult to guarantee that the system will preserve the current set of requirements. A software traceability tool can support this effort by linking the program to the vast amount of information that is being maintained. More specifically, tracing maps between all the artifacts of the system being developed. Artifacts include documents such as the system definition, interview transcripts, memoranda, software requirements specification, the functional specifications, the design report, user's manuals, and the program's code. Through the links, tracing can provide information concerning accountability for requirements, design and implementation decisions [1]. The ability to track projects and manage design rational are other uses for traceability.

The motivation behind a traceability tool is to validate system features against the requirements specification, identify error sources and manage change [3]. For instance, consider the development of a security system for a bank. In such a system there will be many different stakeholders that includes the development team, bank personnel, customers and experts such as electricians, architects and security specialists. All these stakeholders have a different point of view for the requirements of the system. For example, bank personnel will be concerned about their well-being and accessibility of the system; customers will be concerned about the security of their assets; electricians and architects will give input about how the system can be physically laid out; security specialists provide input on all aspects of the security. With so many points of view coming from all stakeholders, it is difficult to manage them, communicate information to the developers and it is likely that conflictions

in the requirements will arise. This is where tracing of requirements can benefit the software engineer.

With links between the artifacts of the system, we can now keep track of the requirements and changes to them. These links provide for accountability of the requirements and the justification of design and implementation decisions. The main drawback to this is that, with the large number of artifacts that results from developing a large system, the links between the artifacts can be hard to maintain.

This paper introduces an approach to tracing in which the amount of links that need to be maintained are reduced. Although this approach, based on context monitoring, does not support full tracing, it provides a significant subset. Section 2 provides the reader with a background on traceability tools. Section 3 describes traceability in the context monitoring environment. Section 4 presents the initial steps in defining a framework for specifying constraints in a formal language. Finally, section 5 will give a short summary of the paper.

BACKGROUND

The typical approach to maintaining traceability, especially for complex systems, requires that all system artifacts created at various stages of the development process be linked to the requirements. In such an approach there must be hyperlinks (physical links) between all artifacts and requirements. These links should provide bi-directional, vertical and horizontal traceability. Bi-directional traceability refers to the ability to trace both backward and forward. Vertical traceability allows the user to trace between documents developed at different life cycles, and horizontal traceability provides the ability to link between related objects created in the same life cycle. Each document must have a logical structure so that the tracing tool will understand the interrelationships between different software documents. Furthermore, the ability to update the links as the system evolves must be present. With a large volume of documents, however, it is difficult to maintain and update the links between the artifacts [1].

Some approaches to building a traceability tool include: an object-oriented approach and a graph-based approach. In the object-oriented approach, users define the classes of artifacts and the relationships between them. The classes of artifacts provide the logical structure necessary for the documents to be traced. The relationship classes provide the structure for defining links and their relations. The use of relations instead of simple links lets developers distinguish among different links between the same objects. Also, by using properties of relations, this approach can relate objects that are not directly linked [3].

The graph-based approach takes both the coarse-grain level and the fine-grain level of the system into account. On the coarse-grain level, links represent dependencies between whole documents. On the fine-grain level, the structure of the documents are taken into account. Both levels are necessary to provide for adequate traceability. The collection of documents are represented by the use of hierarchical graphs. Operations on the graphs are defined by means of a formal language based on graph rewriting system. On the coarse-grain level, all project documents and the relations between the documents are represented in the graph. On the fine-grain level, links represent the relation between individual objects in the documents. These objects may be contained in the same document or in separate documents [4].

These two approaches to developing traceability tools have one thing in common: they link all artifacts to the requirements. The advantage to having direct links between all artifacts is that one can trace the system and ensure that the system requirements have been met, thus providing more complete coverage of the system. In a system with thousands of interrelated objects, however, too much information must be managed and the user may be overwhelmed with irrelevant data. This also provides for a very complex system of links to maintain.

TRACEABILITY USING CONTEXT MONITORING

This section introduces an approach to tracing, based on context monitoring, that reduces the number of physical links that need to be maintained. In this approach, constraints on the system are used to link the artifacts. As a result, the links between the development documents and the implementation code are replaced with virtual links simplifying the complex system of links that need to be maintained. This approach does not supply full tracing in that it only provides links to the areas of the document that pertain to constraint specification; however, this is a significant subset of tracing.

Context monitoring is an approach to software development that allows us to accomplish this type of tracing. It captures knowledge of the data objects of a software system to ensure program correctness with respect to selected properties. The approach consists of two parts: the elicitation and specification of constraints on data objects being modeled by the system, and a constraint satisfiability mechanism that dynamically verifies constraint enforcement during program execution.

Constraints capture properties, relationships, restrictions and limitations on data or objects of the program and may be used to reflect the interpretations and assumptions that are made about the objects during development. Constraints are elicited from domain experts, users and members of the development team during the analysis and development process. Constraints are not embedded in the program code, instead they reside in a central repository with links to the documentation. This repository contains the constraints expressed in first-order logic along with the relevant information pertaining to the source of the constraint. The satisfiability mechanism virtually links the constraints to the program by tagging code sections with identifiers of the related constraints as described next.

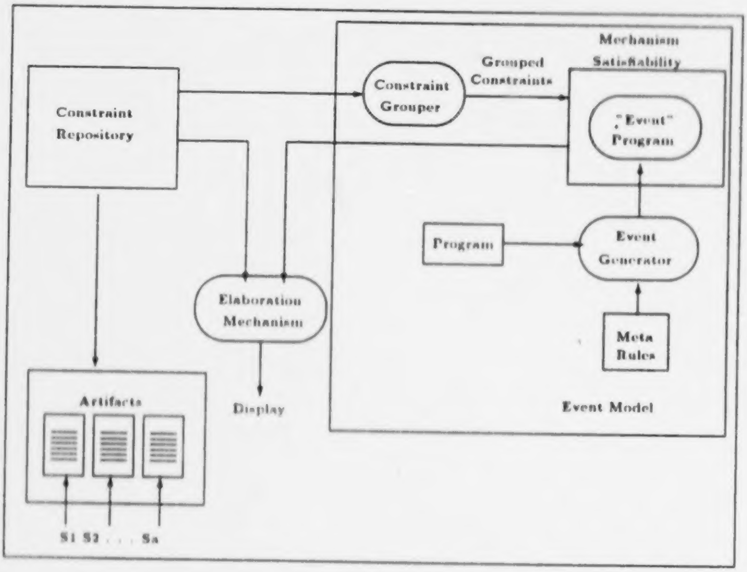

Figure 1: Overview of Context Monitoring with Event the Model

The event model (see Fig. 1) consists of a set meta-rules and the program code that are entered in to an event generator. Meta-rules define where and how to tag a program section with constraints. The event generator uses the rules to tag the program and produces an "event" program. Once this event program is executed, the satisfiability mechanism, an external system monitoring the program, registers state changes and invokes appropriate constraint checks according to the tags [2]. The constraint-grouper gathers all the constraints that pertain to an event. This set of constraints becomes input into the satisfiability mechanism. When a constraint is violated an event occurs. This event is reported to the elaboration mechanism [2].

The elaboration mechanism acts as a bridge between the satisfiability mechanism and the constraint repository providing an interface for tracing. After an event is reported, the elaboration mechanism displays constraint violation and the section of code where the violation occurred. The user then has the option to go into the repository and trace from the constraint to the documentation pertaining to it.

FRAMEWORK FOR SPECIFYING CONSTRAINTS

This section presents the framework being used to develop a tracing tool using context monitoring. The initial steps are to describe a formal language to store the constraints in the central repository, and to define the links that need to provided within the artifacts. Subsequently, we will be implementing a prototype that will visualize the tracing process.

A formal language is used to describe the format for storing the constraints of a program. The formal language is defined using Backus Naur Form (BNF). Each entry in the constraint repository will follow the syntax as described in the following format:

```
<Constraint Spec> ::= <Constraint> : <Source List>;
<Constraint> ::= <Constraint Def>
<Source List> ::= <Source> | <Source> : <Source List>
<Source> ::= <Document ID> , <Specifier ID> , <Date>
<Document ID> ::= <Document Name> ( <Section> )
<Specifier ID> ::= <Person Name>
<Date> ::= <Month> - <Day> - <Year>
<Section> ::= <Number> . <Section> | ε
```

An example of a constraint specification using this format follows:

$\forall$ salary $\in \mathbb{R} \mid$ salary > 10000 and salary < 100000 : SRS(2.3), Tom Watson, 10-4-96 ; interview1(), Francisco Saenz, 10-4-96;

This constraint specification initially describes the constraint in first-order logic and constrains the variable *salary* to values greater than 10,000 and less than 100,000. After the ':' symbol, the source of the constraint (<Source List>) is given. In this case, <Source List> is comprised of <Source>:<Source>, where the first instance of <Source> consists of <Document ID>, SRS(2.3), followed by the <Specifier>, Tom Watson, and the <Date>, 10-4-97.

Links define the relations that exist within artifacts with respect to the constraints. The constraint repository, through the <Source List>, provides virtual links to the documents where the constraint was first specified. Within the documents, sections that discuss the same constraint are physically linked together. The physical links can be in the same or in separate documents in different life cycles. This allows for the bi-directional, vertical and horizontal links as described in section 2.

SUMMARY

Traceability using context monitoring reduces a significant number of physical links that need to be maintained by the tracing tool. This paper provides a framework to implement such a tool. This system will benefit the software engineer in many ways. First of all, the user can obtain information about a specified constraint. For instance, who specified the constrain, what documents specify the constraint and when it was specified. Also, the satisfiability mechanism can report when and where in the program code a constraint was violated. After a violation has been reported, the elaboration mechanism allows the user to trace back into the documents where the constraint was first specified. One disadvantage to this approach is that it is not possible to ensure that all system requirements are met because the constraints capture only those parts of the requirements that specify properties and relations between objects. The advantage to this approach is that the system does not have to provide physical links from the artifacts to the program code; therefore, if modifications to the code are made the links are not inadvertently affected.

ABSTRACT

Computer scientists employ knowledge representation schemes to represent the semantic content of natural language concepts. Representation of knowledge means using a formal language to compose descriptions that correspond to the world. The interest in artificial intelligence is developing descriptions of the world that an intelligent machine can use to derive new conclusions about its environment. This paper describes the construction of a formal world model for the `Joseph` system, a set of programs in the Prolog language which generates short narratives modeled after Russian folktales. The `Joseph` system uses interchangeable world models as its source for the facts and events around which the stories revolve. A world model in the `Joseph` system is a set of prolog predicates which describe the potential characters, events, and range of reactions to events that drive the plot of the story. This paper describes the world model predicates, explains their role in the system, and shows how these predicates capture commonsense observations drawn from example tales. This research contributes to the advance of knowledge representation and artificial intelligence because it demonstrates an understandable and practical means to represent commonsense knowledge about the world in a way that is useful in an automated system.

INTRODUCTION

Computer scientists employ knowledge representation schemes to represent semantic content of natural language concepts [Allen:93]. Representation of knowledge means using a formal language to compose descriptions that correspond to common events and facts. In computer science, these descriptions must be in a form which will allow a computer program to draw conclusions and make predictions based on the represented information. For example, we need to represent two people being married in such a way that the computer can understand that they can no longer marry anyone else or consider themselves single. As another example, a person going on a trip has to be recognized by the computer as someone relocating temporarily. The interest in artificial intelligence is writing down these descriptions of the world in such a way that a machine can derive new conclusions about a given problem domain.

THE `JOSEPH` SYSTEM

The system in which this work has been done worked is called the `Joseph` system [Lang:97]. It is a set of programs in the Prolog language which generates short narratives modeled after Russian folktales. The core of the system is a formal grammar that governs lists of events and facts, which are the terminals in the grammar. The non-terminals are high-level and intermediate components of stories such as `setting`, `episode`, `reaction`, and `outcome`.

```
Example rule:
Story --> Setting, Episodes
```

The system works by generating a list of events and facts, expressed as first-order predicate calculus terms. We refer to this as the "event list." The system also maintains a parse tree of this list. Once the event list and parse tree are finished, both these are sent to a natural language output unit which translate these formal structures into surface text(language in a form that people actually communicate in). Figure 1 illustrates the major components of the `Joseph` system.

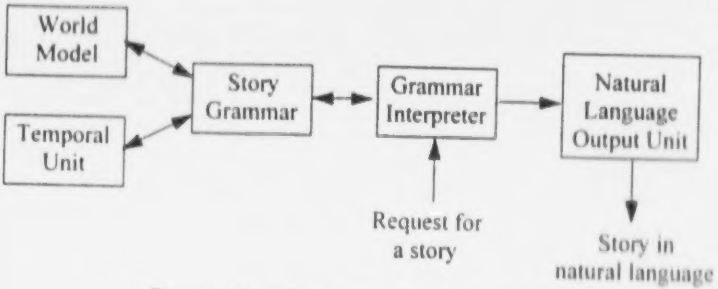

Figure 1: Major Components of the `Joseph` System

During the process of constructing the event list, `Joseph` invokes a world model which describes the events that can happen, the effects that are possible, the reactions characters have, and the goals that characters can pursue. The `Joseph` system uses interchangeable world models as its source for the facts and events around which the stories revolve. The following is a sample story generated by the `Joseph` system.

```
Once upon a time there lived a tsar.

one day it happened that tsar went to the palestine.  when
this happened, tsartisa felt lonely for the tsar.  in
response, tsaritsa waited for tsar to return.  some time
passed.

then king captured tsar.  when this happened, tsaritsa felt
lonely for the tsar.  in response, tsaritsa made it her
goal that tsar would be rescued.  tsaritsa developed a
plan.  tsaritsa rescued tsar.  this is how the plan worked.
tsaritsa disguised herself as the harpist.  tsaritsa went
to the palestine.  tsaritsa entertained king.  tsaritsa
asked the king for the tsar.  tsaritsa selected tsar.  tsar
was rescued.
```

REPRESENTING THE CONTENT OF RUSSIAN FOLKTALES

This particular area of research focused on the world model component of the Joseph story generation system. The system generates a story by performing a top-down construction of a parse tree describing the structure of the story, that is, the facts in the setting, the number of episodes, the number of actions taken in pursuit of a goal, etc. When this generation process reaches a leaf node, the grammar places a terminal schema, or template, at the leaf node. It is the responsibility of the world model, which is separate from the grammar, to instantiate the leaf node.

The following partial parse tree illustrates this. The grammar rules govern the construction of the tree down to the leaf. In this case, a particular event at a particular time is required to start off an episode. The grammar inserts a template at the leaf node and invokes the world model to instantiate it. In this case, the world model must supply some actual event to instantiate the variable `Event`. The temporal module instantiates `Time` to ensure that events happen in the proper sequence.

BEST COPY AVAILABLE

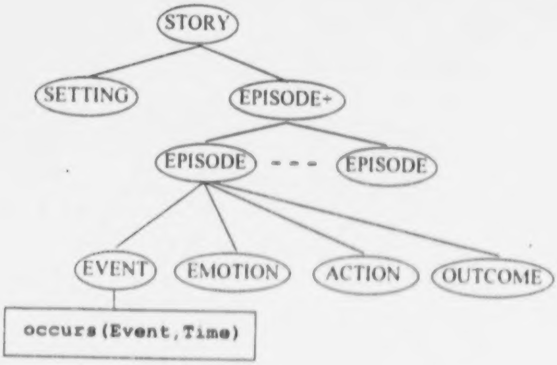

Figure 2: A partial parse tree for a simple narrative showing a leaf template

A world model in the Joseph system is a set of prolog predicates which describe the potential characters, events, and range of reactions to events that drive the plot of the story. The world model is very detail oriented in that it describes the characters that can appear in stories, events that can happen to characters, reactions characters have to these events, actions that characters take, and the goals that characters adopt.

The Joseph world model relates specific actions, events, and states to each other. For example, the action of eating is related to the effect of being satisfied. This information allows the system to determine the effects of agents actions in order to detect, for example, when a goal has been achieved. Most of the relationships in the world model are valid only when certain other conditions are true or particular actions have previously taken place. For, this reason, most of the required world model predicates accept an argument which describes the state of the world. The predicates use this argument to determine if the conditions for a particular relation have been met.

A Joseph world model has two types of predicates: required predicates and auxiliary predicates. Required predicates are the predicates that the grammar invokes in order to instantiate a leaf. The other predicates, auxiliary predicates, are used internally by the world model to support the required predicates. A sample required predicate utilized by the Joseph system is:

```
hero(Agent).
```

The agent of a story is the protagonist of a story. For example, the clause `hero(cossack)` states that a story may have a cossack as its central character. The agent must then be classified into a specific gender by usage of the `gender` predicate, an auxiliary predicate.

```
gender(tsaritsa, female).
```

This defines the tsaritsa as being female in the world of Russian folktales.

Another required predicate is the `fact` predicate, `fact(Fact,World_state)`. This predicate is used in the developing the setting of a story.

```
fact(married _to(Prot, tsar), World):-
        protagonist(Prot, World),
        gender(Prot, female).
```

This defines the protagonist of a story is married to the tsar in the given world. The condition for this fact is that the protagonist be female, since the tsar is male.

Another required predicate is `action_motivation(Emotion, Action, World)`. This specifies the action that an agent who feels emotion will perform in `World`.

```
action_motivation(miss(Spouse), wait(Spouse,return), World):-
     user:protagonist(Prot,World),
     holds_in(married_to(Prot, Spouse), World)
```

The protagonist's emotions are expressed in the missing of the spouse, therefore her action is to wait for the spouse's return. The final line of the clause states the condition that the protagonist will wait for spouse only if the protagonist is married to the spouse.

One final example of a required predicate is `episode_primitive(Event, World)`. An episode primitive is an event in a story that can initiate an episode.

```
     episode_primitive(go(tsar,palestine),_World).
```

This states that in any world state the tsar can go to Palestine.

LIMITATIONS OF THE PRESENT WORLD MODEL

Although much work and effort has been put into the development of knowledge representation techniques, problems still remain. These issues surface in `Joseph` and cause incoherent stories. Sometimes characters reappear after being pronounced dead. Characters sometimes remarry without any resolution to their previous marriage. The system should be able to identify that if someone is dead that they are no longer in existence. A sample story that depicts this error follows.

```
once upon a time it happened that cat wanted food.  when this
happened, peasant felt pity for the cat.  in response, peasant
made it his goal that cat would be fed.  peasant attacked mare.
mare killed peasant.  peasant believed it impossible that cat
would be fed.  cat was starved.

then the younger daughter of baba_yaga went to the palestine.
when this happened, peasant felt lonely for the younger daughter
of baba_yaga.  in response, peasant waited for the younger
daughter of baba_yaga to return.
```

As another example, if someone is married the only way that they should be able to marry again is if they divorce or if their spouse dies. Consider the following story.

```
once upon a time there lived a wolf.  wolf was married to wife.

one day it happened that imp possessed daughter of a boyar.
when this happened, wolf felt love for the daughter of a boyar.
in response, wolf made it his goal that he would be married to
the daughter of a boyar.  wolf exorcised the imp from the
daughter of a boyar.  wolf was married to daughter of a boyar.
```

The above story allows the wolf to marry the daughter of a boyar, without any resolution to the previous marriage established in the setting.

The world model contains the rules which incorrectly allows these stories to be created. Out task is to identify the mistakes in the rules and correct them so that the machine can develop intelligent stories that are sensible to the reader. The following is a clause stored within the world model.

```
effect(attack(mare), state(killed(Prot, mare)), World) :-
     user:protagonist(Prot,World).
```

This clause states that the effect of attacking a mare is being killed. The world model allows or accepts a character as being dead or killed, but doesn't understand that in the state of death that a

BEST COPY AVAILABLE

person can no longer carry out further actions. This incompleteness causes incoherent stories in which killed characters go on to act in subsequent episodes.

The clauses below, used in the second story, contains an error with respect to marriages.

```
can_marry(P1,P2) :-
     gender(P1,male),
     gender(P2,female).

can_marry(P1,P2) :-
     gender(P1,female),
     gender(P2,male).
```

The only restrictions placed on marriage by these clauses is that the characters marrying be of opposite genders, there is no mention of previous marriages. A facile correction to this particular problem follows.

```
can_marry(P1,P2,World) :-
     gender(P1,male),
     gender(P2,female),
     \+ holds_in(married(P1,World)).
     \+ holds_in(married(P2,World)).
```

This clause now states that, in addition to the parties to the marriage being of opposite genders, they also may not already be married. Notice that, in order to determine whether the characters were already married, it was necessary to add an additional argument to the predicate.

RESULTS

This research has brought computers a step closer to being able to draw conclusions about a particular environment. This work has shown how a commonsense world can be encoded and used in a larger system. The research has also revealed limitations of the scheme used in the `Joseph` system. These limitations fall into two major categories: (1) incomplete descriptions of events and actions, and (2) interactions among events and actions (the ramification problem). Although limitations of the first type are relatively simple to correct, the ramification problem is not so easily solved.

FUTURE WORK

Although some incoherent stories can be eliminated by identifying incomplete world model predicates and adding conditions to them, this approach will not solve all the problems. For example, the difficulty with dead characters continuing in subsequent episodes cannot be solved by adding conditions to a single clause. Instead, we must add conditions to *every* other clause stating that the agent must be alive. Such a solution is awkward and introduces the problem that, with every new action or effect we add to the world model, we risk having to consider the interactions of that new action or effect on everything already contained within the model. This is an instance of the frame problem known as the ramification problem [Shoham:88], which is currently an unsolved in knowledge representation.

Dr. David B. Teague

There exist many links and similarities in the fields of mathematics and computer science; this paper explores a link at the foundational level. Kurt Godel published his Incompleteness Theorem in 1931, and Alan Turing published his solution to the Halting Problem in 1937. Although these results are native to two different fields, the techniques that each individual used are nearly identical. This paper explores the link between these results and the methods used to arrive at these results.

INTRODUCTION

Since it will serve as a natural introduction to the content of this paper, I shall first briefly introduce the content and background of Godel's Incompleteness Theorem and Turing's Solution to the Halting Problem. Following this short introduction, I will proceed to outline proofs to the theorems, proofs to which we can refer.

In 1900, David Hilbert delivered a famous lecture outlining a list of problems for mathematicians to work on in the coming century. As an answer to the problems Hilbert saw arising in Set Theory, one of his problems asked that it be proven that mathematics is consistent and complete. By 'consistent' we mean that there does not exist a statement such that the statement and its negation are both theorems. By 'complete' we mean that all mathematical truths are theorems. With the publication of Kurt Godel's famous work in 1931, he showed that these conditions cannot both be true. In more general terms, Gödel showed that any axiomatic system at least strong enough to support natural number arithmetic cannot be both complete and consistent, shattering Hilbert's hopes that the contrary was the case.

Now let us consider the Halting Problem. The Halting Problem can be stated as follows: Given an arbitrary algorithm and an arbitrary input, decide if the algorithm will eventually halt on the provided input. In looser terms, this is a "pull the plug" question. Consider, for example, a computer program to find solutions to Diophantine Equations. [Suppose that our computer is theoretical; that it does not have an upper bound on the numbers it can represent.] What happens when our program has been running for several hours (or longer), displaying solutions to the provided input equation. Are there infinitely many solutions, or a finite number, all of which our program has not yet found? It would be convenient if we could first feed this program and its input into a "terminator-tester" to see if the program will eventually halt (implying a finite number of solutions) or not halt (implying an infinite solution set). In 1937, Alan Turing published a paper demonstrating the unsolvability of the Halting Problem.

These two results shook the Mathematics and Computer Science communities. Each is native to separate but related academic fields. The rest of this paper is dedicated to exploring links between Godel's Incompleteness Theorem and Turing's Solution to

BEST COPY AVAILABLE

the Halting Problem (hereafter referred to as the Halting Theorem), particularly in the method of proof employed to arrive at each.

GÖDEL'S INCOMPLETENESS THEOREM

Before we explore links between the theorems and their proofs, we should acquaint ourselves with the nature of the proofs. The formal proof of Godel's Incompleteness Theorem is rather detailed and involved, so the reader should be aware that I will not repeat that depth here. When Gödel first published the theorem, he was concerned that it be extremely tight and error-free as possible. The complete proof is readily available, so the reader should refer directly to Gödel's document for a more rigorous proof (found in REFERENCES section).

Godel starts his proof by placing it in the context of a formal axiomatic system. The theorem generalizes to any system at least strong enough to support natural number arithmetic; but let us here refer to our system as TNT (Typographical Number Theory), after Hofstadter's reflection of Gödel's proof (438-460).

The next step is to number all symbols used in TNT, thus numbering all statements of TNT. Now a derivation rule can be interpreted as an arithmetical manipulation of a natural number. For a more in-depth demonstration of this technique, consult Hofstadter (261-264).

Next consider one form of the well-known Epimenides paradox, "This sentence is false." This string is self-contradictory: if it is true, it declares its own falsehood; if it is false, it again contradicts itself. Relating to Gödel's proof, Godel's job is next to find a self-referential string of TNT, say 'G', that in effect asserts that "G is not a theorem of TNT," or "G is unprovable." Thus G is a self-referential statement, similar to the Epimenides sentence above. Of further interest is the fact that G asserts its own nontheoremhood. Next consider the following questions and statements from Hofstadter (448):

> Is G a TNT-theorem? If so, then it must assert a truth. But what in fact does G assert? Its own nontheoremhood. Thus from its theoremhood would follow its nontheoremhood: a contradiction.
>
> Now what about G being a nontheorem? This is acceptable, in that it doesn't lead to a contradiction. But G's nontheoremhood is what G asserts--hence G asserts a truth. And since G is not a theorem, there exists (at least) one truth which is not a theorem of TNT.

So in other words, assuming TNT's consistency, we now know that G asserts a truth, but G is not a theorem. (Thus it cannot be proven by means of a series of derivations from a given set of axioms.) Hence we have an undecidable proposition, and thus the incompleteness of TNT.

Although the proof of which is beyond the scope of this paper, Godel demonstrates two more important properties of TNT. First Godel shows that "plugging up the hole" doesn't work. That is, as soon as we add G (or even G's negation) as an axiom of TNT, we find another string, say G', that is undecidable in the new system. This process can continue indefinitely, and in a manner reminiscent of Cantor's diagonalization trick to prove the uncountability of the real numbers, Gödel shows that TNT is forever incomplete as long as it is consistent. Second, Godel addresses the consistency issue. He expresses the sentence "TNT is consistent" inside of TNT, then shows that the theoremhood of this statement only holds when TNT is inconsistent! Thus there is no rigorous proof that can demonstrate TNT's consistency.

In Godel's original paper, he actually worked with a system titled *Principia Mathematica* (PM), slightly different from TNT. I have borrowed TNT from Hofstadter's work, a major source for this paper. But remember Godel also demonstrates that the aforementioned results hold for any formal system at least strong enough to contain natural number arithmetic.

With all this said, we will next move to the Halting Problem and Halting Theorem. We will continue by exploring links between Godel's Incompleteness Theorem and the Halting Theorem, particularly in their proofs.

THE HALTING PROBLEM

Now we turn our working environment to the context of Turing Machines (TMs). Recall that we can formally define a TM in terms of set theory, but suffice it to say here that a TM is simply a manifestation of an algorithm (provided we accept Church's Thesis). The proof of the Halting Theorem that I will mimic here is not quite the same as Turing's original proof, but the concepts involved are extremely similar. The majority of the proof outlined in the rest of this section is adapted from Cohen (807-809).

Let us start by developing a numbering system for TMs. Any numbering system will suffice, as long as there exists a bijective mapping from a subset of the natural numbers to the set of all TMs. Now let us restrict our TM input string alphabet so that TMs take as input a single natural number. For an example to TM encoding, consult Brookshear (176-181).

Now we are set up very nicely to feed the encoding of a TM as input to another TM. In the spirit of Cohen (726), let us now define the language ALAN as the set of all TM encodings that either do not represent TMs or represent TMs that do not accept their own encodings as input.

A key point that will soon be a crux to our argument is the fact that ALAN is not recursively enumerable (abbreviated r.e.). To see this, consider the following argument quoted from Cohen (727-728).

Suppose there does exist some TM, say T, that accepts the language ALAN. (That is, suppose ALAN is r.e.). Now we ask if the encoding of T, code(T), is a member of ALAN:

Case 1: code(T) is in ALAN

CLAIM	REASON
1. T accepts ALAN	1. definition of T
2. ALAN contains no TM encoding that is accepted by the TM it represents	2. definition of ALAN
3. code(T) is in ALAN	3. hypothesis
4. T accepts code(T)	4. from 1 and 3
5. code(T) is not in ALAN	5. from 2 and 4
6. contradiction	6. from 3 and 5
7. code(T) is not in ALAN	7. rejection of hypothesis

Case 2: code(T) is not in ALAN

CLAIM	REASON
1. T accepts ALAN	1. definition of T
2. If a word is not accepted by the TM it represents it is in ALAN	2. definition of ALAN
3. code(T) is not in ALAN	3. hypothesis
4. code(T) is not accepted by T	4. from 1 and 3
5. code(T) is in ALAN	5. from 2 and 4
6. contradiction	6. from 3 and 5
7. code(T) is in ALAN	7. rejection of hypothesis

The contradictory results force us to reject our original hypothesis, that ALAN is r.e. Whence ALAN is not r.e., and no TM exists that accepts exactly those strings in ALAN.

Now we are prepared to suppose that there does exist some TM, say HPA (halting problem answerer), that takes as input the

BEST COPY AVAILABLE

encoding for some other TM, say T (not necessarily the same T as from the previous argument), and input to T, say w. Let us define HPA to reach its halt state if w halts on T, else HPA crashes.

Now that we have HPA, we modify it to obtain a new TM, say NASTY, as follows: First change the halt state of HPA to an infinite loop. Next change all crashes of HPA to successful HALTs. The input to NASTY will be a single TM encoding. So now, in essence, NASTY runs the encoding of T on T itself and loops if T accepts its own encoding and halts if T does not accept its own encoding.

Note that NASTY accepts exactly those strings that are a member of ALAN. But because ALAN is not recursively enumerable, there cannot exist a TM that accepts exactly the language ALAN. Thus we have a contradiction. This forces our hypothesis, that HPA exists to be false. Therefore we have demonstrated the unsolvability of the Halting Problem.

LINKING THE THEOREMS

Both of the two aforementioned theorems are extremely important in that they assert truths concerning the foundations of mathematics and computer science. So now that we have acquainted ourselves with the nature of the theorems, let us continue by exploring links and key themes common to the two theorems (as promised in the title of the paper), first in the similarities in the proofs.

Formalization and Numbering

The first fundamental step in each proof is to formalize the context of the proof. For Godel this means first working in *Principia Mathematica*, a highly formalized system developed by Russell and Whitehead. Although Godel later generalizes to any sufficiently strong system, the system must be definable in a formal, typographical manner.

Similarly, when Turing first started his work on the halting problem, he had to set up a context in which to work. For Turing this meant developing Turing Machine Theory. Other sufficient, formal computational models have been developed such as Post Machines and Minsky Machines, but have since been demonstrated to have equivalent computational power as TMs.

The next crucial step is to develop a numbering or encoding system. Virtually any encoding scheme will work, so the details as to how to develop a scheme are omitted here. For encoding examples, consult Hofstadter (267-269), or a Theory of Computation Text such as Brookshear (176-177) or Cohen (721-726).

Self-Reference and Epimenides Paradox

Probably the most crucial aspect to both theorems is the method of self-referential contradiction. This is done rather easily in spoken language, with such statements as "This sentence is false," or "I am lying." But the pearl of Gödel's argument is his ability to "get arithmetic to talk about arithmetic"! (Hofstadter, 17-19). The details as to how this is done is beyond the scope of this paper, which is why we did not specify earlier in arithmetical terms exactly what G is. Then, not only is G self-referencing, but also contradictory in the spirit of Epimenides.

Similarly, once we are able to supply as input to a TM an image of itself, we have a self-referential mechanism for TMs. Then again we can use this self-reference in a manner to arrive at an Epimenides-style contradiction. Note that for the proof provided here of the Halting Theorem, the Epimenides Paradox rears its head in showing that ALAN is not r.e., ALAN being a language that bears self-referential properties.

Recursive vs. Recursively Enumerable

Recall that for a set of strings (in either a formal system or a language) to be r.e. means that the strings can be generated according to typographical rules or some grammar. The stronger condition of *recursive* means that not only is the set of strings r.e., but so is its complement. For a classic example of a r.e. language that is not recursive, consider the complement of ALAN.

Recall that ALAN is a classic example of a language that is not r.e. Therefore strings in the language cannot be captured precisely by a phrase-structure grammar. However, the complement of ALAN is r.e. Similarly for formal systems, just as with formal languages, "there exist . . . systems whose negative space (set of nontheorems) is not the positive space (set of theorems) of any formal system." (Hofstadter, 72) Consider the following pictorial representation (Fig. 1) of this scenario, taken from Hofstadter (71).

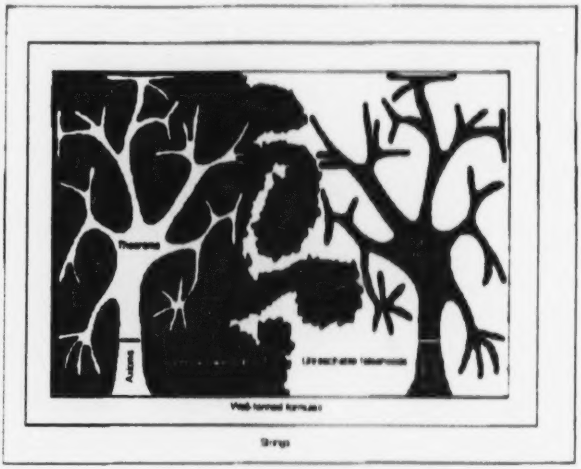

Figure 1

In terms of the figure, Godel's string G is contained in the 'unreachable truths' region. (Assuming TNT, or other sufficiently strong system, is consistent.)

CONCLUDING REMARKS

In this paper, I have explored in detail two foundational results to Mathematics and Computer Science. I have shown how many techniques, such as self-referential paradox, are used to arrive at both results. So, in essence, I have looked at one way to "Link the Foundations of Mathematics and Computer Science."

Bob Neveln

INTRODUCTION

In May of 1995 Sun Microsystems announced their new product, the Java language. This new language became very popular and widely used within a couple of years. The major reason for such high popularity was because the Java language enabled programmers to create real-time interactive programs that could be downloaded and executed on any computer regardless of the operating system. At the same time, the introduction of the Java language raised a lot of concerns about the security and safety of the network. This article will try to analyze and explain security problems associated with the Java language.

JAVA LANGUAGE

With the Java language it became possible to write programs that could be downloaded over the network as an already compiled code, and then executed on any computer that has a Java platform. Usually the programmers refer to the Java programs that have the above property as applets. First, let look at how the Java designers were able to achieve compatibility. In order to create a program a programmer usually has to do two things: first, write a program code, and second, compile it. The second stage will create a code that is usually understandable only for the machine that compiled the program. It is obvious that a program compiled on one machine usually won't run on another machine because of the differences in their architectures. The applet compatibility is achieved because of the so-called "Java Virtual Machine". After an applet is written in Java language, it is compiled to create a so-called bytecode, which is a sequence of eight-bit codes that can be executed only by the "Java Virtual Machine"(Yellin, 1996). So, in order for an applet to become an animation or real-time interactive program it has to go through a number of steps. First, a programmer should write a Java program. Then the program should be compiled and referenced in the HTML file. So, when the HTML file is accessed from the network, a compiled Java program will be downloaded on the computer along with it.

This obviously opens a lot of threats to the computer that downloads the applet. Usually an applet is downloaded behind the firewall (if there is one) and therefore it has the same permissions as any other regular process on that computer. Also, since an applet is downloaded as an already compiled program, it is impossible to predict what it will to do. It is obvious that such a policy is unsuitable or even dangerous for the networking, and that is why Java language needs special security restrictions on the action an applet can perform. The Java language designers included four security levels that make the language safer.

JAVA SECURITY LEVELS

The Java language has four distinguishing security levels. Those security restrictions help to stop applets from possible hostile actions, and limit the range of action that an applet can perform.

The first level of security is the Java language itself. The Java language was built on the C programming language base and as a result those two languages have a lot of things in common. However, the Java language is a well defined language. All of its primitive data type are of a specific size, and all of the operations in the Java language are performed in a specific order. In contrast to C, the Java language does not allow programmers to use pointers, forbidding straight references to the main memory. There are no pointers or any pointer arithmetic in the Java language. All the memory deallocation and allocation are done automatically by the Java language interpreter. The Java language has an automatic garbage collector that runs as a low priority thread. Also the Java interpreter and Java compiler source codes are available for inspection, so that they can be analyzed and verified (Frequently Asked Questions – Applet Security, 1997).

The second level of security is a bytecode verifier, that checks if the downloaded applet was created by a trustworthy compiler. This verification is performed during the Java runtime and is totally independent of the Java compiler. During this stage an applet downloaded from the net is checked to see if it obeys the Java language control rules. There is a small theorem prover inside the Bytecode Verifier that insures that the downloaded code:

- doesn't forge pointers
- doesn't violate access restrictions
- doesn't access objects improperly
- doesn't call methods with inappropriate arguments
- doesn't have stack overflow
- doesn't have illegal data conversions (Yellin, 1996).

The third level of the Java Security is a Class Loader, that defines a way of loading of the applets classes into the system. The Class Loader makes sure that each of the loaded classes works only within its own private namespace, and does not violate other classes' namespace limits. The Class Loader distinguishes between local Java defined classes and new downloaded classes and loads them into separate namespaces even if they have the same names. The class loading is also executed in a Java runtime and is used to ensure correct references to classes by determining whether a class is downloaded or Java local.

The last level of the Java security is a so-called access control list (ACL) which takes care of the file protection and the network access. In general applets downloaded over the network are not allowed to do any of the following things: read or write into the computer's file system, get system information, connect over the network to the other computers, execute native calls, and communicate with the other applet. On the other hand, applets loaded from the local drive, are permitted to do all of those things. However, all these properties can be modified by a user.

JAVA LANGUAGE SECURITY PROBLEMS

Despite Sun Microsystems's attempt to build a reliable security for the Java language, a number of bugs, design flaws, or other security breaches were found in the structure of the language. Most of the problems that were found were related to the improper implementation of the security policies, or simple design flaws, such as inadequate restrictions on the amount of the computer resources an applet can use. A careful examination performed by Princeton researchers shows a possible way to bypass security restrictions creating a class loader. A DNS bug that allows an applet to connect anywhere on the net it wants was also found. It violates one of the Java security policies which says that an applet can connect only to the computer from which it was downloaded (Drew, Felten, and Wallach, 1997).

Another type of security problem that Java has to deal with is a so-called Denial-of-Service attack. By definition, a Denial-of-Service is consuming computer resources with an intention of making them unavailable to others. Recently a Java source code of the hostile applets that perform Denial-of-Service attacks appeared on the net. Generally, those hostile applets are small and compact Java programs that consume CPU cycles and allocate memory until there is none left. As a result of such hostile actions, the user usually has to either quit browser or reboot the computer (LaDue,1996). There are couple of twists that make hostile applets even more dangerous. First, applets can wait a specified amount of time before starting to waste computer resources, which make it very difficult to trace applets' source. Second, instead of consuming all the computer resources, applets can cause degradation of service, meaning significantly slowing down performance of the browser without terminating its activity (Drew, Felten, and Wallch, 1997). Third, it is possible instead of wasting resources in a malicious way, simply to use them. In other words, since an applet has freedom to use as much computer as it wants, someone may use those computer resources for his/her own purposes (such as complex calculations that are performed on a victim's machine and reported back to the attacker's computer). Despite all that, Sun Microsystems considers Denial-of-Service attack a low priority problem.

DENIAL-OF-SERVICE ATTACKS

It was decided to research Denial-of-Service attacks more deeply and try to find how are they implemented in Java. First, hostile applets written by Mark LaDue were analyzed, in order to get a better understanding of how Denial-of-Service attacks work. It was found that usually hostile applets have a couple of similar characteristics. First, the actual hostile action is usually performed in a threads, and to make the thing work even faster, a hostile applet can run several thread that will consume resources or do other malicious actions. Second, Java stop() method should kill an applet and all its thread after leaving the homepage, but it is usually overwritten so an applet performs its action long after the user visited attacker's homepage. Third, usually an applet sleeps a specified amount of time before kicking in, so it is hard to trace where the applet came from. Fourth, hostile applets can catch OutofMemoryError, InterruptedException, ThreadDeath, or any other Java defined exceptions that are supposed to confront such malicious behavior, and handle them in their own way (LaDue, 1997).

So the structure of a hostile applet is rather simple. A hostile applet that executes denial of service attacks can consist only of three or four methods (Figure 1). First method is a init() method that will initialize all the variables. The second is a stop() method that actually does nothing but overwrite a Java default method that stops applet's actions after the user has left a homepage where an applet resided. The third method is the one that consists of hostile action. It, for example, can have an infinite loop that will repeatedly create threads that perform useless calculations, for example, the calculation of the factorial or Fibonacci number, or any other actions that waste computer resources. The part of the program that performs hostile actions is wrapped in a try{ <actions>} catch(<exception>) {<actions>} structure that will do "necessary" actions if a Java exception will be thrown. Certainly, this is only the sketch of possible Java based Denial-of-Service attack, and someone with a good imagination can find thousands of better ways to perform this type of attack. However, even such a simple program proved to be rather dangerous and very effective.

```
public class HostileApplet extends Applet implements Runnable{
        // define all the global variables
        ...
 public void init(){
        //initialize all the global variables and define local variables
        ...
        //call the resources consuming method
        ConsumeResources();
 }

 public void stop{
        //do nothing
 }

 public void ConsumeResources(){
    try{
    //do wasteful calculations
    ...
    }catch(...) //catch possible exception or an error that might occur
       {
       //perform actions that will take care of the exception or an error that
occured
       ...
       }//end of catch
  }//end of ConsumeResources()
}//end of an Applet
```

Figure 1: General Structure of a Hostile Applet.

Obviously, all of the troubles occurred because of the failure of the Java language to enforce a certain policy that would prohibit or at least restrict the overwriting of the stop() method or handling of vital exceptions by an applet. However, in all of the cases the target of a hostile applet that performs Denial-of-Service attack are computer resources. So the best way to fight the Denial-of-Service attack is by restricting the amount of computer resources that an applet can use. Certainly, every process requires a certain amount of computer resources, but it is impossible to predict before execution how much of a memory or CPU time a program will need. Therefore, instead of explicitly specifying the amount of the computer resources an applet can use, it would be a better idea to monitor the applets' activity. So, whenever an applet is on the edge of exhausting the computer resources, a user will have the possibility either to kill an applet or perform other actions that will prevent the system or browser from crashing. Currently, the ways of creating a program that will monitor the applet's activity and will prohibit wasteful use of computer resources are being investigated.

CONCLUSION

The Java language opened a range of new possibilities to improve the World Wide Web, but on the other hand it also created a variety of security problems. Although the Java language was designed to be safe in a network/distributed environment and allow users to run real-time applications, a number of flaws were found in its security design. This paper discusses the major security levels of the Java language and different types of security problems that were discovered, particularly the Denial-of-Service attacks. The Java language designers did a great job trying to make the language secure, but apparently it is not enough, and there is plenty of room for improvement.

Dr. John H. Stewman

ABSTRACT

Groups of marine mammalogists in the Tampa Bay area use photo-identification to gather data about *Tursiops truncatus*, the common bottlenose dolphin. Hundreds of photographs are taken each year and manually identified by the comparison of the characteristic nicks, notches, and scars of the fins with those in previously identified photographs. A computer vision system is being developed which will match new fins with previously identified dolphins and organize the images in rank order based on the similarity of the new fin to the database fins. This Digital Analysis to Recognize Whale Images on a Network (DARWIN) software will eliminate the need for the tedious process of manual photo-identification. Previous work resulted in the creation of image processing routines that produce, with minimal user interaction, a list of 220 points that approximate the fin outline. In May of 1996, DARWIN was moderately successful at identifying dolphins by matching one dimensional mathematical representations of the fins known as centroid signatures. Analysis of matching results identified two major factors which degraded the quality of the match: displacement of the centroid due to variations in the user designation of the beginning and end of each fin outline, and distortion of the fshape caused by out-of-plane rotations of the fins. The focus of current research is to improve the accuracy of the matching system. A preprocessing step, which allows the user to modify the fin shape and orientation to compensate for in and out-of-plane rotation of the dorsal fin, has been added. A method has also been devised to correct the centroid during the matching process in a way that minimizes error by comparing the signed differences in the two signatures and estimating the shift necessary to bring the two fin outlines into closer correspondence. The software has been tested by using the preprocessing module to create a set of corrected outlines which are then used as inputs to the improved signature matching routine. These revisions produced a significant improvement in DARWIN's performance.

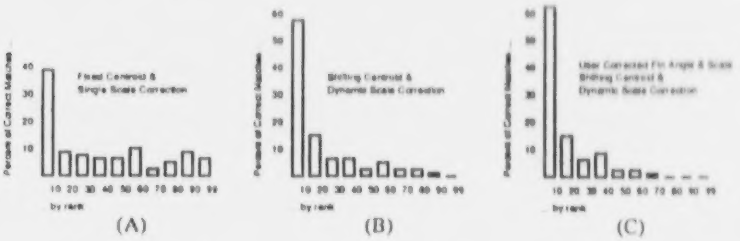
BACKGROUND

During the last three years, there has been an ongoing joint project in Eckerd College's computer and marine science departments, a study of *Tursiops truncatus*, the common bottlenose dolphin. The marine science students study association patterns, local population sizes, preferred habitats, behavioral tendencies, and other characteristics of the dolphins. To gather the data they need, the researchers use a system of photo-identification. They yearly take hundreds of photographs of the dorsal fins of Tampa Bay area dolphins and visually identify them by comparing the new photographs with previously identified ones. The researchers examine the characteristic nicks, notches, and scars of the fins to identify individual dolphins. Unfortunately, photo-identification is a very time consuming process. Photo-identification is also subject to human error. After many hours of tedious and repetitive photo-identification, researchers may become tired or bored, increasing the risk of misjudgments.

A group of Eckerd's computer science researchers have been working on computer applications that will automatically identify the dolphins from digitized images of their fins. This software will minimize the need for the tedious process of manual photo-identification. UNIX/X Windows and IBM PC/Microsoft Windows applications are being developed to provide networked access to a central database of dolphin images and related observational data. Current development is focused on the creation of computer vision systems that will match new fins with previously identified dolphins and organize the images in rank order based on the similarity of the new fin to the database fins. Previous work on both versions

BEST COPY AVAILABLE

of DARWIN resulted in the creation of image processing routines that produce, with minimal user interaction, a list of 220 points that approximate the fin outline. These point lists are known as snakes because they are fit accurately to the fin boundary through an iterative process that makes them appear to slither (Kass, Witkin, and Terzopoulos 321). The X Windows version utilizes a number of image processing routines from the Vista software library (Pope and Lowe). In May, 1996, Mark Allen of Eckerd College finished matching process for the PC version of DARWIN that compares the overall shapes of dolphin fins by matching one dimensional mathematical representations of the fins known as signatures (Allen). A signature is a measure of the distance from the fin centroid to its outline as a function of angle, and is sampled for each degree in the range of 0 to 359. Allen's signature matching routine was tested on a set of one hundred dolphin fin images from forty-five dolphins found in Sarasota Bay. As shown in figure 1(A), for each of the one hundred dolphins, the other images that correctly matched it were listed in its top ten only forty percent of the time. The goal of current research is to improve the accuracy of DARWIN's matching system.



(A) (B) (C)

Figure 1: Signature Matching Performance by Rank Order of Correct Matches

RECENT DEVELOPMENTS

The first approach taken was an attempt to create an entirely new matching system that would focus on the nicks, bumps, and notches that humans use to identify the individual dolphins. A set of routines that creates a filled polygon from the snake points was implemented. Several of the routines used were adapted from Graphics Gems (Glassner). An implementation of the classical thinning algorithm, which was intended to produce the medial axis of the fin and a set of branches that point to each bump and notch on the fin boundary, was added to the DARWIN system (Pavlidis 200). Unfortunately, the thinning algorithm produced only a medial axis, a line from the tip to the base of the dorsal fin. The medial axis alone provided insufficient detail to uniquely characterize the fin shape, so this approach to improving DARWIN's matching results was terminated.

The focus of current research has been to find ways to improve upon Allen's centroid signature matching process. Allen's results are based on a matching process which compares scaled signatures. Each signature is scaled only once so that its mean value is 100 units. For two signatures, the error at a given angle is the difference in the corresponding distance measures. The quality of a match is defined as the mean squared error between the two signatures, considering only the range of angles across which both signatures are defined. Since rotating a signature simply shifts the distance values along the angular axis, the best match between two fins occurs at a relative rotation which minimizes this mean squared error. Figure 1(A) shows Allen's results on 100 fin images.

Analysis of matching results identified three major factors which degraded the quality of the match: movement of the centroid because of variations in the user designation of the beginning and end of each fin outline, sensitivity of signature scaling to these same terminal points, and the affects of out-of-plane rotations on fin shape.

A method has been devised by the faculty advisor to correct the centroid during the matching process, in a way that minimizes the mean squared error. The signed differences in the two signatures are compared and an estimate is made of the shift necessary to bring the two fin outlines into closer correspondence. Specifically, the signed differences between the two signatures is computed at corresponding angles in a twenty degree arc left and right of the centroids. The differences on the left are subtracted from those on the right of the centroid and an average is computed. This value gives an accurate estimate of how far to the left or right one centroid should be moved to improve the match.

$$Hshift=\frac{\sum_{a=170}^{190}((sig1(a)-sig2(a))-(sig1(a+180)-sig2(a+180)))}{21} \qquad (1)$$

A similar estimate is made for the amount of vertical shift. However, the base of the fin is open, so the signature is undefined there. The vertical estimate is made simply by averaging the signed differences between the two signatures at each angle in the upper hemisphere (0 to 180 degrees).

$$Vshift=\frac{\sum_{a=0}^{180}(sig1(a)-sig2(a))}{181} \qquad (2)$$

These shifts are only estimates, but work very well in an iterative process which brings the signatures into closer correspondence.

The scaling problem is minimized by scaling the signature based only on the region of signature overlap. This minimizes the differences due to signature values at the extreme ends of the fin outlines, areas where the two signatures rarely overlap, and where the signature values tend to be at a maximum. This matching process produced significantly improved results over the previous one. See Figure 1(B). Its greatest shortcoming is its exhaustive nature. Improvements to the algorithm efficiency are being developed.

An ideal dorsal fin photograph is one taken with the fin perpendicular to the camera, and dolphin level at the water's surface. Unfortunately, the images taken by researchers are rarely ideal. When dolphins are photographed before they have quite surfaced, or after they have begun diving, the fin is rotated in the image plane. Dolphins are often swimming toward or away from the boat as they are photographed. Additionally, the dolphin may be rolled on its side or the photographer may be at high elevation relative to the dolphin. The foreshortening effects of perspective cause distortions of the dolphin fins and the snakes that are fit to their outlines. Distortion of the snakes produces dramatic changes in the signatures which represent the fins during the matching process.

A solution to this problem was implemented by the author in the X Windows version of DARWIN as a preprocessing step which allows the user to manipulate snakes in three dimensions, thereby correcting each of the rotational effects. The user loads a previously created snake from text-file storage, manipulates it, and saves the improved version. The user has the options of sliding, scaling, and rotating the snake so it more closely resembles one which would have been created from an ideal photograph.

To prevent shape degradation, a working snake array of floating point numbers is created. After each manipulation, the array is converted to integers for display purposes, but the next manipulation is always applied to the floating point array. This minimizes the rounding error, thereby allowing snakes to be loaded, manipulated, and saved with virtually no shape degradation. As the user applies incremental rotations using mouse selectable buttons, a sum of the rotations about the x and y axes are kept. X is the horizontal axis, y is the vertical axis, and the z axis points into the screen. After each rotation, a projection plane is rotated about the x and y axes based on the current sums. The original snake points are projected back from the image plane into the projection plane, which is the best estimate of the three dimensional plane that contained the fin when it was photographed. This projection plane is then rotated parallel to the image plane so that the user sees the fin as it would have appeared if the original photograph had been ideal. In-the-plane rotation corrections are applied immediately to the floating point array.

In the snake manipulation interface, shown in Figure 2, the user is provided with a large square that is used as a guide for resizing and repositioning the fin. The user scales the snake so that it nearly fills the box, and applies rotations until satisfied. The improved snake can be saved to a file.

These preprocessing routines were used to produce an improved set of Allen's original one hundred snakes. The original photographs were displayed simultaneously with the snake, so that the in and out-of-plane rotations could be accurately hypothesized. After the manipulation process was complete, the set of one hundred corrected snakes was fed through the improved signature matching routine. As indicated in figure 1(C), the user correction of angle and scale further improved the results of the matching process. It is especially important to note that seventy-seven percent of the correct matches were ranked in the top twenty. This means that the researcher will only have to search through one fifth of database to find the correct match for the fin in a new photograph every three out of four matches.

CONCLUSION

The centroid signature matching scheme of DARWIN was greatly improved. The X Windows version of DARWIN was ported to an IBM PC with the Linux operating system. This will allow a greater number of users to access the software, and enhances its portability. In the near future, DARWIN will be made available to Eckerd College's dolphin photo-identification researchers for testing. This application of computer vision will help alleviate the problems of manual-photo-identification.

INTRODUCTION

In the last century, scientists have theorized about the different possibilities and advantages in creating communications networks and devices (Willner, 1997); however, these theories often remained dormant until advances in technology allowed for their design and fabrication. This problem exists with the efficient use of the tremendous bandwidth available in fiber optic communications. Communication developments, such as the internet and video teleconferencing, have increased the demand placed on the current fiber optic network (Blumenthal, Shell, and Vaughn, 1997). As a result, the technical community is seeking an efficient device to transmit multiple wavelength information channels on a single fiber optic line.

Due to their low attenuation and excellent data transmission, the world currently uses the wavelengths of 1.31 μm and 1.55 μm to transmit data through fiber optic cables (Keiser, 1983). However, Figure 1 shows that 1.55 μm receives about half as many attenuation losses as 1.31 μm. Why use 1.31 μm? Originally, 1.31 μm demonstrated lower dispersion losses than 1.55 μm making it a better device for most types of transmission (Keiser, 1983). However, advances in fiber technology reduced the dispersion losses that 1.55 μm experienced, thus making it the best wavelength for data transmission. In order to utilize the current fiber optic cables originally setup for 1.31 μm transmission, the technical community developed fused fiber coupler (FFC) which multiplexed and demultiplexed these two wavelengths. However, FFCs do not accommodate the increasing demands placed on the current fiber system.

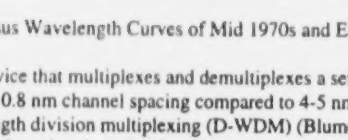

Figure 1: Attenuation versus Wavelength Curves of Mid 1970s and Early 1980s (Keiser, 1983)

Now consider a device that multiplexes and demultiplexes a set of closely spaced wavelength channels (e.g., 0.8 nm channel spacing compared to 4-5 nm channel spacing). This is known as dense-wavelength division multiplexing (D-WDM) (Blumenthal, Shell, and Vaughn, 1997). Such a device must have low insertion loss, low crosstalk, and be easily mass produced (Keiser, 1983). The novel device presented in this paper demultiplexes the communication wavelengths of 1.31 μm and 1.55 μm using the Talbot theory of self-imaging.

The following paper presents the theory and background of a novel WDM device, as well as preliminary experimental data from the first fabrication run. The conclusion will assess the potential product with regard to its performance requirements and its viability in the communications industry.

THEORY

Talbot Effect in Waveguides

The design of a wavelength division multiplexer (WDM) is based on the concepts involved in the Talbot effect. The Talbot effect in an optical waveguide is a process of self-imaging along the lateral direction of a Multi-Mode Interference Region (MMI Region) (Soldano and Pennings, 1995). Figure 2 shows a perspective view of a self-imaging waveguide device.

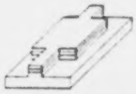

Figure 2: Perspective View of a One-to-One Self-Imaging Waveguide Device

Light entering the input rib decomposes into many lateral modes which propagate through the MMI region at different velocities. As the modes propagate through the MMI region, they will accumulate a phase difference. The modes will constructively interfere and reproduce the image when they accumulate a phase difference of 2π--a process known as self-imaging. The distance required to self-image at a certain wavelength is the self-imaging length. Figure 3 shows a numerical simulation of the self-imaging process.

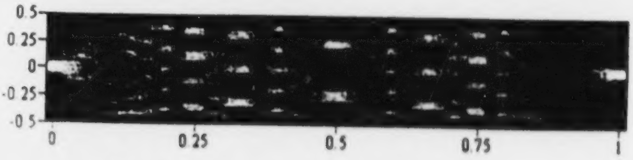

Figure 3: Numerical Model of the One-to-One Self-Imaging Process

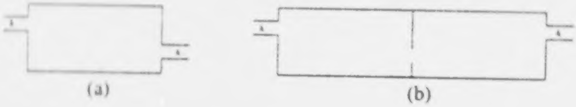
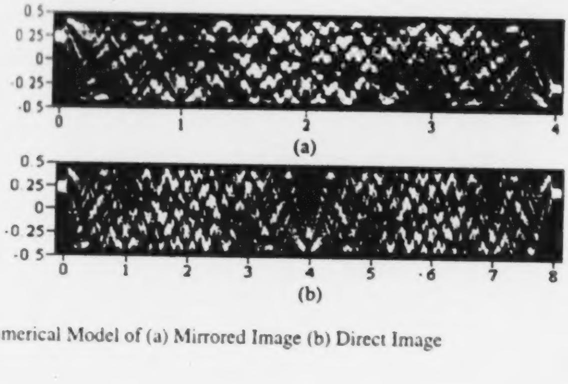
Device Design

Producing a device which spatially separates two wavelengths requires offset and separated outputs, as shown in Figure 4a. The formation of a single self-image will form an image positioned diagonally from the offset input. This image is referred to as a "mirrored" image. The formation of two self-images produces an image directly across from the input as seen in Figure 4b. This image is referred to as a "direct" image. Figures 5a and 5b show the corresponding numerical models of the "mirrored" and "direct" images.



(a) (b)

Figure 4: (a) Mirrored Image (b) Direct Image



(a)

(b)

Figure 5: Numerical Model of (a) Mirrored Image (b) Direct Image

For the device to work, it required a common MMI length for both wavelengths. Mathematically manipulating the equations caused 1.31 µm to form an odd number of self-images (mirrored images); while 1.55 µm formed an even number of self-images (direct images). Several factors affected this modeling process; these include the MMI width, MMI length for each wavelength, and the effective index for each wavelength. In the model, a small difference between the effective width (Goos Haenchen effect) and the actual width exists. This is due to the large difference in the indices of refraction between our materials ($GaAs$ and $Al_{0.3}Ga_{0.7}As$) and air. Figure 6 shows the effective width and the actual width as part of the waveguide structure.

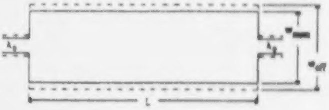


Figure 6: Waveguide Structure with Actual and Effective Widths

The different cases used the specified MMI region widths of 10 µm, 16 µm, or 20 µm and used the effective index method to determine the waveguide's transverse index of refraction at $\lambda_o = 1.55\mu m$ ($n_{mmi,1.55} = 3.3282$) and at $\lambda_o = 1.31\mu m$ ($n_{mmi,1.31} = 3.3590$). In order to obtain the MMI length at 1.31 µm, the following equation is used:

$$L_{1.31} = \frac{4n_{mmi,1.31}W_{mmi}^2}{\lambda_o}(2p-1), \tag{1}$$

where $L_{1.31}$ is the (2p-1)th self-imaging length at λ_o equal to 1.31 µm, and W_{mmi} is the width of the MMI region. For the wavelength of 1.55 µm, the following equation is used:

$$L_{1.55} = \frac{4n_{mmi,1.55}W_{mmi}^2}{\lambda_o}(2q), \tag{2}$$

where $L_{1.55}$ is the (2q)th self-imaging length at λ_o equal to 1.55 µm. To obtain the general equation for the MMI length from the equation determining the beat length of the region:

$$L_\pi = \frac{\pi}{\beta_0 - \beta_1} \cong \frac{4n_{mmi}W_{mmi}^2}{3\lambda_o}, \tag{3}$$

where β_o is the propagation constant at mode 0, β_1 is the propagation constant at mode 1, and L_π is the beat length (Soldano and Pennings, 1995). Three beat lengths equal one self-imaging length. After determining the MMI length for each wavelength, the most common match was found; five self-imaging lengths for 1.31 µm and six for 1.55 µm. Figure 7 provides an example of the matching process for both MMI lengths.

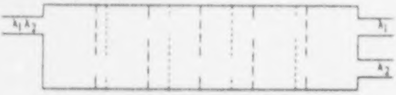

Figure 7: A Common MMI Length for the Mirrored and Direct Images

After mathematically determining the length for each wavelength, two computer programs simulated the performance of the device. These simulations examined the possible throughput efficiency (coupling efficiency), which aided in determining the optimum length for each wavelength. Table 1 provides the data used in modeling the devices. Figures 8a and 8b show the intensity profiles for 1.31 µm and 1.55 µm at the output of the MMI Region; the graphs show the crosstalk present. Of the cases modeled, Case 4 demonstrated the best throughput at 93% (0.3 dB excess loss).

Table 1: Predicted Values for 5 Case Studies

	Rib Width (μm)	MMI Width (μm)	$L_{mmi,1.31}$ (μm)	$\eta_{1.31}$ (%)	$L_{mmi,1.55}$ (um)	$\eta_{1.55}$ (%)	Δd (μm)	Average L_{mmi} (μm)
Case 1	2	10	5115	79.2	5133	70.5	18	5124
Case 2	2	16	13131	57.0	13190	59.5	60	13160
Case 3	2	20	20481	59.3	20606	46.1	125	20553
Case 4	4	16	13131	92.9	13188	93.2	57	13159
Case 5	4	20	20496	89.3	20611	83.0	115	20553

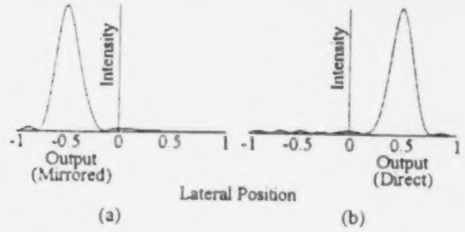

Figure 8: Intensity Profiles (a) 1.31 μm (b) 1.55 μm

After determining the dimensions, lay-out of the device structure followed. Several design configurations were used to minimize errors or loss in the system. The primary device averaged the lengths of the MMI region as shown in Figure 9a. The large depth of focus, approximately 10 μm, enables averaging the lengths. Another model staggers the outputs by using the optimum lengths of the MMI region for each wavelength. Figure 9b shows the staggered output MMI region. If the walls of the staggered output facet cutoff any modes, then additional losses may occur. The final model tapered the outputs, as shown in Figure 9c; losses may result from scattering in this model.

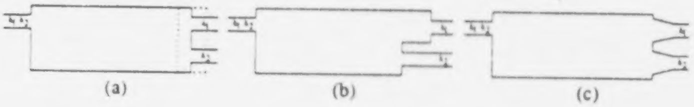

Figure 9: MMI Region with (a) Averaged (b) Staggered (c) Tapered Output Lengths

The optimization process also required consideration of the narrow MMI width. The fiber cladding is significantly larger than the lateral spacing between output ribs. Figure 10 shows the use of S-bends to separate the output rib spacing. S-bends allow for practical use of the devices by pig-tailing the ends. Variation in source wavelength also poses a potential problem. The design and fabrication of devices with varying MMI lengths aided in avoiding this problem.

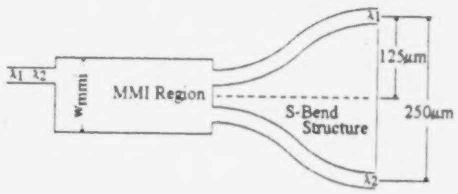

Figure 10: S-bends

Summary

The device is based on the Talbot effect in waveguide structures. The device will possess many more advantages than FFCs, such as a reduced fabrication cost due to mass production using existing integrated circuit fabrication processes. FFCs use a computer for fabrication of each individual device, making it a more costly device--approximately $300 each. In addition, a variety of device structures accounted for possible fabrication tolerances.

EXPERIMENT

The experiment began with device fabrication. The fabrication process involved molecular beam epitaxy (MBE), and magnetic-enhanced ion etching (MIE). Due to a long length of the devices and the space available on the wafer, many of the case 3 and case 5 device structures not fabricated. Of the fabricated devices, case 4, shown in Table 1, predicted the best throughput.

Time constraints only allowed for the testing of the open faceted device. Figure 11 shows and open faceted device. This device demonstrates whether the device actually works, which it did. Figures 12a and 12b show actual, experimental images and intensity levels versus the width of the MMI Region for both wavelengths. Figure 12 shows the working device; however, a lot of cross talk existed. The crosstalk may result from inaccurately positioning the device at the end of the MMI region.

Figure 11: MMI Region with Open Facet

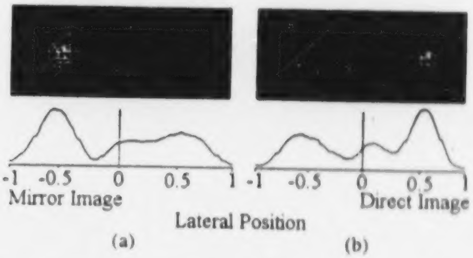

Figure 12: Output Images and Intensity versus Width Plots for (a) 1.31 μm (b) 1.55 μm

CONCLUSIONS

The need to expand the use of current fiber optic cables to meet the demands of more users on the system has led to the development of wavelength division multiplexing. The increasing need to expand and utilize more bandwidth requires a much improved solution to the current fused fiber couplers which only separate two wavelengths. One solution to this problem is to use D-WDM. The novel device presented only demultiplexes two wavelengths; however, it is a large stepping stone to the fabrication and utilization of D-WDM.

The first fabrication run resulted in a working device. Compared to the open faceted device, the remaining structures should yield positive and improved results. In addition, data obtained from the characterization of the first run devices will aid in the fabrication of improved and more efficient devices in the future.

ACKNOWLEDGMENTS

We would like to thank Dr. George F. McLane, U. S. Army Communications/Electronics Command, Fort Monmouth, NJ, for performing the Magnetic-enhanced Ion Etching (MIE).

THE UNIVERSITY OF NORTH CAROLINA at ASHEVILLE
JULY, 1997

Foreword for the
Proceedings of the Eleventh National Conference on Undergraduate Research
University of North Carolina at Asheville
April 24-26, 1997

The University of Texas at Austin was pleased to host the 1997 National Conference on Undergraduate Research, affirming its commitment to excellence in undergraduate education and to the research experience in particular. Over 2100 students and faculty attended some 1500+ oral, poster and performing or visual arts presentations scheduled over April 24-26. A special feature of NCUR '97 was a series of more than 30 presentations by faculty members from all disciplines demonstrating the integration of research and teaching with the new technologies. These presentations were capped by a performance on Saturday night of "Ears and Feet," a concert of new interdisciplinary work by student and faculty composers, choreographers, dancers and performers from the UT College of Fine Arts. Electro-acoustic music and modern dance explored interactivity of disciplines and technologies by allowing dancers' movements to control electronic music and robotic lighting by way of a touch-sensitive computer dance floor.

President Robert M. Berdahl opened the conference quoting a Chinese proverb: "I hear and I forget. I see and I remember. I do and I understand." Berdahl praised the research experience as the most practical and potent method to provide students the perspective of inquiry, innovation and exploration as they prepare "for a future that is not so much known to be uncertain, but instead, certainly unknown." That facts and methodologies become obsolete in a world in which developments and advances occur with dizzying rapidity points to the importance of incorporating research activity into the undergraduate experience.

Dr. Berdahl also praised the student-faculty relationships that are fostered by the research process, congratulating the faculty mentor for serving the educational needs of the talented and motivated students by participating in the adventure of exploration and discovery, of cooperation and collaboration which characterize academic life.

Five distinguished plenary speakers addressed conference participants throughout the three days. Dr. Steven Weinberg, Nobel laureate in physics and professor at the University of Texas at Austin, challenged listeners to consider the future of science by posing the questions "The End of Science?". Dr. Robert Williams, Director of the Space Telescope Science Institute, dazzled the audience with the most recent images from the Hubble Space Telescope. From the vastness of space to the minute complexity of genetic research, Dr. Steven McKnight of the UT Southwestern Medical Center at Dallas introduced conference participants to the fascinating work being done in gene regulation and cell differentiation. Friday night's fete "Texas Culture Swing" featured, in addition to an outstanding sampler of culinary and musical styles of the Lone Star state, a mini-plenary address on the multifaceted aspect of Texas border cultures by Dr. Rolando Hinojosa-Smith, distinguished author and professor of Creative Writing. NCUR 97 closed with a resounding standing ovation upon conclusion of "The Challenge of Leadership" by Sarah Weddington, J.D., former Texas legislator and White House assistant, now author, lecturer and adjunct professor.

The University of Texas at Austin is proud of the privilege to share our campus for these few days with the distinguished group of students and faculty whose work is presented here in published form. We congratulate you for your accomplishments and encourage you to continue to participate in the challenge of research.

Susan Wells Howard, Chair, NCUR '97

PREFACE

The 407 papers published in these five volumes are representative of the approximately 1825 papers and posters presented at the celebration of undergraduate research that was NCUR '97'. The faculty, staff and students of the University of Texas at Austin are to be commended for making NCUR '97' such an enriching experience. The student authors deserve recognition for their hard work and for their persistence in seeing their research through to its final publication.

Special thanks are extended to Dr. Susan Howard, Ms. Kelly Johnson and other members of the NCUR '97' staff. Their help during the days of the Conference was invaluable. Many thanks also to the members of the National Board, who reviewed a large number of papers submitted to the Proceedings under time constraints. Their continued efforts to standardize has raised the Proceedings quality. This project would have not been successful without their assistance.

I would also like to thank the UNCA Editorial Board, who put in many long hours reviewing, checking and organizing papers, and Tracy Walker, and Adam Bradley, who did all the cutting and pasting necessary for these volumes. I owe a special debt of gratitude to Katherine Whatley, Tracy Walker and Mila Cleverdon for their support, encouragement, and mentorship during the entire process of organizing the Proceedings.

To all the students who submitted papers to the Proceedings go thanks for their participation and congratulations for their achievements. Your enthusiasm and achievement will serve as role models for the next group of student researchers - whom we look forward to meeting at the Twelfth National Conference on Undergraduate Research at Salisbury State University, Salisbury Maryland.

MODIFICATION OF AN INTERFERENCE PATTERN THROUGH PARTICLE STATISTICS: EXPERIMENTAL STUDY

Niranjan Sharma

Department of Physics
University of Northern Colorado
Greeley, CO, 80639

Faculty Advisor:

Willard Fadner

Using a green He-Ne laser (543.5 nm) as a light source, a double slit as an interference device and a photomultiplier tube as a photon counting apparatus, comparisons of the shapes and intensities of double slit interference patterns are made using differing intensities of incident laser light. Patterns with low intensity and long exposure are compared with those from high intensity and short exposure, as well as with the theory. A mismatch in the relative intensities, as a function of angle, of the bright versus dim patterns has been observed. A possible explanation is that the higher intensity regions could be the result of two-photon or three-photon counting instead of single photon counting. The experimental goal reported on here is to further examine the cause for the unexpected variations in intensity. This will involve modifying the discrimination level for the photo multiplier signals, using faster electronics to reduce any signal pileup, and carefully measuring the light intensities to be used.

INTRODUCTION

It has been shown (Demster and Batho, 1927) that photons passing through an interference device after long term accumulation produce the expected interference patterns. Quantum mechanics requires that the interference pattern produced should depend on the total number of photons events and not on the rate at which these events occur. So even when the intensity is so low such that only a photon at a time interacts with the slit, the wave theory predicts the correct average pattern after accumulation. Interference patterns produced from exposure to dim light after long periods of accumulation should be the same as those produced from exposure to bright light with relatively short periods of accumulation, provided the number of total photon events are the same for both cases. Quantum theory states this to be true because of the equal probability in each case. The original intent of the experiment was to test the patterns from short term bright light and those from long term dim light accumulations, as well as to compare them with the theoretical pattern. The previous experimental results[5] did confirm that the location of the double slit peaks agreed with the theoretical prediction. However the shapes of the envelopes were not consistent for the patterns obtained for different intensities of light. Patterns of relatively dim light had a good theoretical fit, but for relativity bright light the sides of the central maximum and the first order maximums were far too low. My intention in writing this paper is to explore the proposed model of multiple photon events as a possible cause of the mis-match between theory and experiment formed in the previous work. The goal of further experimentation is to investigate the mismatch in the pattern envelope for the different intensities of light by using different levels of discriminator settings applied to the signal. By adjusting the lower level discriminator settings we are able to discriminate against signals with certain pulse heights coming out of the amplifier. In this process by increasing the discriminator we are trying to eliminate signals resulting from multiple-photon events which have relatively higher pulse height than the single-photon events.

EXPERIMENTAL PROCEDURE

The basic setup of the experiment remained essentially unchanged from earlier work. The laser light is transmitted through removable neutral density optical filters and then a double slit (see Figure. 1).

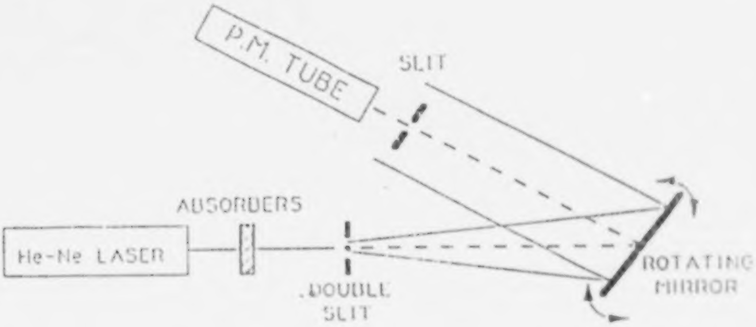

Figure 1. Basic Experimental Setup.

The desired intensity of light is obtain through appropriate use of filters of various densities. Photons emerging through the double slit are reflected off a rotating mirror to a photomultiplier tube with an adjustable detector slit. The rotating mirror is driven by a stepper motor where each step of the motor corresponds to 2.63 x 10^{-4} radians. The mirror steps the interference pattern counterclockwise through 255 channels (6.68 x 10^{-4} radians) of the photomultiplier tube. After the data has been accumulated in all 255 channels, the mirror is stepped clockwise in reverse, without accumulation, 255 channel to the original starting position. We are using a Hamamatsu R1463-01 1/2 inch diameter photoelectric tube (with multialkalai cathode) as the detector. This has an advertised quantum efficiency of 10% at 543.5 nm (Hammamatsu, 1984). The photomultipler tube is cooled by placing it in a Thron EMI cooler to reduce the dark count as much as possible. All background light is essentially eliminated by placing this entire system in a light-tight box.

Figure 2. An electrical schematic of the experiment.

An electrical schematic of the experiment is shown in Figure 2. The photomultiplier tube is powered through a 1000 volt bias supplied by a Tennelec TC 952 High Voltage supply. Signals out of the PMT are processed with an ORTEC 9301 fast preamplifier and then through an ORTEC 570 shaping amplifier. The signal from the shaping amplifier is then sent to an ORTEC 551 timing single channel analyzer (SCA) with discriminator. At this stage various discriminator settings are applied to the incoming signal from the shaping amplifier. From the SCA, a TTL signal for each pulse is sent to a multichannel analyzer (MCA). The MCA was manufactured by The Nucleus, and contains in one of the abus boards for an IBM compatible computer. Synchronization between the mirror movements and data acquisition is controlled by a BASIC program, developed locally, employed on a Sinclair QL computer. When taking data at different incident light intensities, the only changes made to the experimental apparatus were in the filters providing absorption before the double slit, and in the number of passes.

RESULTS & DISCUSSION

The patterns obtained through exposure to dim light after long accumulation had a good theoretical fit for different discriminator settings (see Figure 3). The vertical axis represents the number of counts and the horizontal axis represents the channel number.

Patterns at three different lower level discriminator setting is shown, at 0.15 volts, 0.34 volts and 0.5 volts. The curve superimposed on the pattern, represents the theoretical single slit envelope and it is scaled in height to best match the data in the center of the pattern for each of the settings. The dim light plot for a low discriminator level of 0.15 volts shows a considerable amount of background noise; the signal rests above the noise. The theoretical fit is reasonably good at all the discriminator levels for patterns of dim light. Therefore, the discriminator setting has little effect upon the interference pattern for dim light. This is consistent with the idea that dim light results in mainly single photon events.

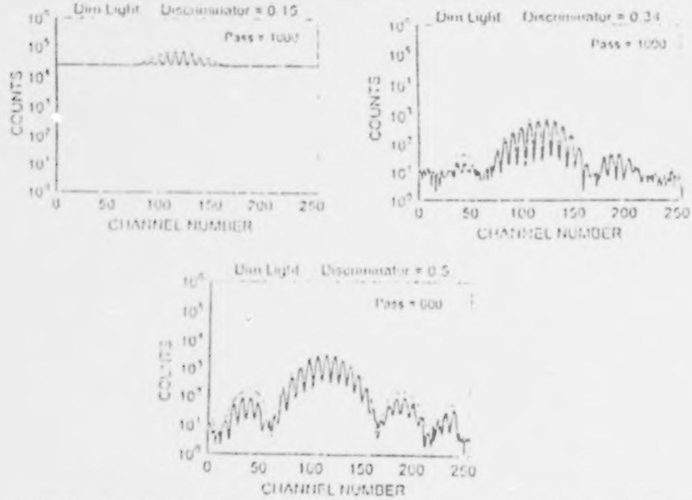

Figure 3. Dim Light Patterns for various discriminator settings.

Puzzling results were obtained for patterns of medium light (see Figure 4.). The intensity of light here is about 100 times brighter than dim light. The central region of the pattern is a closer fit to the theoretical for lower level discriminator setting, this is as expected since at lower level mostly single-photon events dominate. As the discriminator level is increased the first order maximum deviates from the theoretical curve, this is consistent with the idea that as the lower level discriminator is increased multiple-photon events become more prominent. However, this observation should have increased as the discriminator setting is increased, but as seen in Figure 4, for discriminator settings of 0.5 volts and above, the pattern is a good fit to the theoretical. The 543.5 nm He-Ne laser that was used for the experiment began pulsing during these later runs. We have since found out that the power supply for the laser was damaged, causing this pulsing. At this point we believe the effects seen for the medium light could be caused by the malfunction of the laser. And further experiments are currently being done with a new 543.5 nm laser to reproduce different patterns seen for medium light. The bright light runs not shown here, fit the model well. At lower discriminator levels for the bright light the theoretical was a good fit to the experimental result and at higher discriminator levels the inconsistency was seen between the theoretical and the first order.

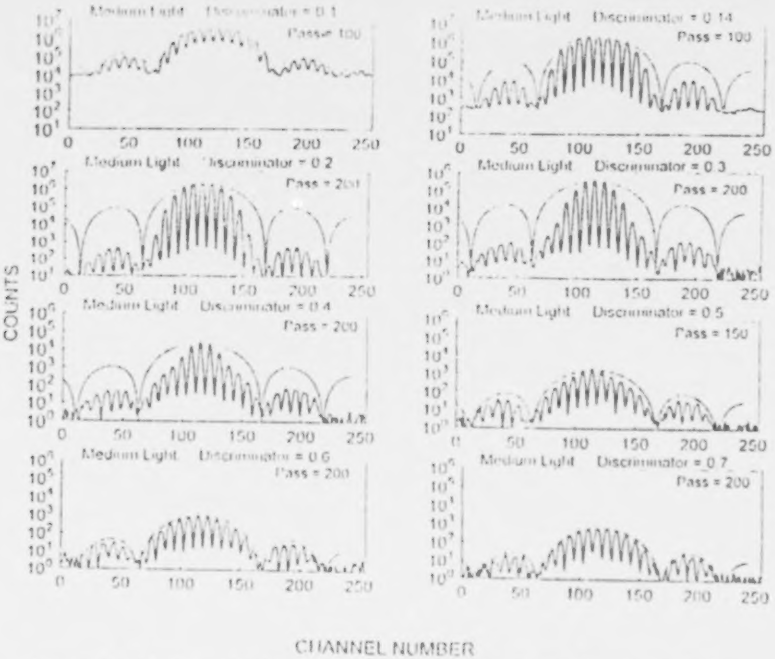

Figure 4. Medium Light patterns for various discriminator settings.

CONCLUSION

The discriminator setting does have an effect on the interference pattern of relatively medium and bright light. It however does not effect the pattern accumulated through exposure to dim light. This is consistent with the idea that for relatively dim light, single-photon events are more probable. Since the interference pattern for medium light deviates from the theoretical envelope for the values in the mid range of discriminator setting, the pattern is being affected by the discriminator. But since this behavior is not seen at higher settings of the discriminator further experimentation is needed before a definite conclusion is drawn.

The level schemes of the even mass tellurium nuclei A=124, 126, 128 and 130 have been constructed by measuring the de-excitation gamma rays following excitation of a target nucleus by inelastic neutron scattering. Level schemes were developed by identifying gamma-ray cascades with a multiple detector arrangement. Combined with additional information obtained from gamma ray angular distribution data, the evolution of nuclear structure across an isotope chain becomes apparent. Results are compared with IBM-2 and PCM model calculations.

INTRODUCTION

There are 8 stable tellurium isotopes. This number of isotopes is exceeded only by the 9 of Xenon and the 10 of Tin. This great number of isotopes allows one to examine the evolution of nuclear structure for a near continuous range of neutrons.

Two fundamental difficulties arise in constructing the perfect theoretical description of nuclear structure. First, unlike atomic structure, an exact form for the interaction potential cannot be constructed. Second, the sheer number of particles involved, on the order of 130, makes the full calculation intractable. Different techniques of handling these two fundamental difficulties lead to different nuclear models. There are two basic nuclear models, the independent particle shell model and the collective model.

The most rigorous treatment is the independent particle model. It is observed that there are significant jumps in the values of binding energy per nucleon at neutron or proton numbers = 2, 8, 20, 28, 50, 82, and 126. This is analogous to the shell model of atomic structure, and these so called "magic numbers" represent major shell closures. Simplifications can be made by assuming that all the properties of the nucleus come from the valence particles/holes beyond the closed shells. Calculations become unmanageable for nuclei with many particles occupying ≥6 orbits. The independent particle model is very effective for nuclei with lower mass numbers.

Collective models are based on motion of the nucleus as a whole rather than individual particle motion. These models attempt to account for general properties that vary smoothly across a range of mass numbers. For near-spherical nuclei, energy added to a nucleus excites surface oscillations about the equilibrium shape. The fundamental vibrational modes are referred to as phonons. This has been effective in predicting many low lying levels. For deformed nuclei, rotation of the static nuclear shape leads to a level scheme well described by a classical rotor. Historically (Bohr 1969, Novarov 1987) the general situation is modeled by constructing a Hamiltonian to describe the motion of interspersed neutron and proton fluids. Most modern calculations use an algebraic treatment known as the Interacting Boson Model-2 (Iachello 1984, Otsuka 1985) because of its ease of use and the ability to describe intermediate situations between vibrations and rotations.

Hybrid models have been constructed which combine features of the collective and particle models. The Particle-to-Core Coupling models (PCM) (Heyde 1967) treat states in the tellurium nuclei as a valence pair of protons orbiting a Sn nucleus which is allowed to undergo vibrations. One can then introduce additional terms in the Hamiltonian to allow interactions between the valence particle-pair and the phonon vibrations.

All the different models are capable of placing some energy levels, but none are capable of placing all of them. Through experimental determination of what levels actually exist, it can be seen in what regions each model is effective, and possible improvements to the current models can be postulated. There is no perfect unified nuclear model.

EXPERIMENTAL PROCEDURE

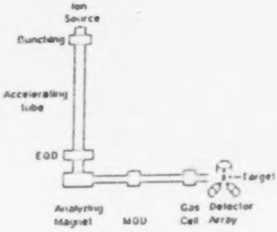

Figure 1. Layout of the University of Kentucky's 7.0 MV Van de Graaff accelerator and beamline used for coincidence measurements.

Data used in this investigation were taken during the summers of 1994-1997 at the Nuclear Structure Laboratory at the University of Kentucky. This Van de Graaff facility (Fig. 1) is capable of accelerating protons, deuterons, ^{3}He, and alpha particles in either a continuous or pulsed beam mode. In pulsed beam mode, a Klystron terminal bunching system produces beam bursts with pulse width less than 1 ns with 531 ns spacing between pulses, and can deliver greater than 2 μA of protons on target. The use of pulsed beams allows one to significantly reduce background in the detector spectrum, improving the signal-to-noise ratio. Protons of a specific energy are selected by passing through a 90° analyzing magnet. Electric and magnetic quadrupole doublet lenses focus the beam. The protons then strike a gas cell filled with tritium to produce neutrons with the $p + {}^3H \rightarrow n + {}^3He$ reaction with a Q-value of -0.76 MeV. The sample of interest is hung in the emerging cone of neutrons.

With the normal operating limits of the accelerator being ~1.5 MeV to ~6.5 MeV, neutrons are available from ~0.7 MeV to ~5.7 MeV. The gas cell is cylindrical, 1 cm in diameter, 3 cm in length, and lined with tantalum to suppress background (p,n) or (d,n) reactions. The tritium gas is separated from the beam line by a 7.6 μm Mo foil. The emerging neutron beam then passes through a paraffin shielded collimator and strikes the target. The use of pulsed beams allows one to significantly reduce background in the detector spectrum, improving the signal-to-noise ratio.

Samples were ~100 gm of natural tellurium chips and ~30 gm of isotopically enriched ^{124}Te powder. The containers were suspended in front of the neutron beam and surrounded by lead shielding and three detectors. Each detector was placed approximately four centimeters away from the sample. Two of the detectors were n-type Ortec high-purity Ge detectors of 51% and 57% efficiency with a resolution of about 2.1 keV at 1332 keV. The third detector was an n-type PGT HPGe detector of 32% efficiency with a resolution of about 2.5 keV.

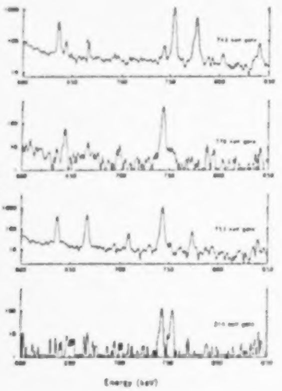

Figure 2. A portion of the γ-ray coincidence data gated on the low lying levels of ^{128}Te.

To identify the gamma-ray cascades, data was taken in "event mode" -- when at least two detectors fire, the energies from all detectors are written to disk for later off-line analysis. A correlation matrix is then constructed which correlates the energy in one detector to the energy in another. Cascade sequences are discovered by slicing rows out of the matrix and observing which γ-rays occurred in the other detectors. This projection is referred to as gating.

Level schemes were built by constructing 1-D histograms (projections) for the four known low lying transitions ($2_1^+ \rightarrow 0_1^+$, $4_1^+ \rightarrow 2_1^+$, $2_2^+ \rightarrow 2_1^+$, and $6_1^+ \rightarrow 4_1^+$) in each nucleus. All states in nuclei tend to cascade down to the ground state through these four levels. These four histograms can be displayed as a graph of yield versus gamma ray energy (Figure 2).

Lifetimes of the tellurium excited states are determined with the Doppler Shift Attenuation Method (Belgya 1994). When a nucleus is struck by a neutron, it recoils accordingly. If the lifetime of the excited nucleus is short, it can decay while it is still moving. If it does, the observed energy of the resulting γ ray will be altered by the Doppler effect. The size of the Doppler effect depends on two factors: the decay-weighted average velocity and the angle of detection relative to the recoil. For the neutron energies available at the University of Kentucky, lifetimes in the range of a few femptoseconds to a few picoseconds can be determined. The uncertainties, however become quite large near the limits.

Angular distributions of de-excitation γ rays were measured at a neutron energy of 2.60 MeV. The angular distributions were fit to even-order Legendre polynomial expansions and compared to theoretical calculations from the statistical model code CINDY (Sheldon 1966) in order to deduce level spins and parities and to extract multipole-mixing ratios.

DISCUSSION

The anticipated structural concerns are readily apparent when one examines the mass dependance of selected levels (Fig. 3). The 2_1^+,4_1^+, and 2_2^+ states show the parabolic increase expected of vibrational states as the neutron number varies from mid-shell. For neutron numbers above mid-shell, the 6_1^+ state remains a constant excitation energy indicative of the added neutrons going into a single particle orbit.

Vibrational models are constructed from the creation-annihilation operator formalism. A creation operator d^+ is defined which creates a (quadrupole) phonon containing two units of angular momentum (i.e. d denotes a d-state). The IBM-2 (Otsuka 1985) Hamiltonian is of the form:

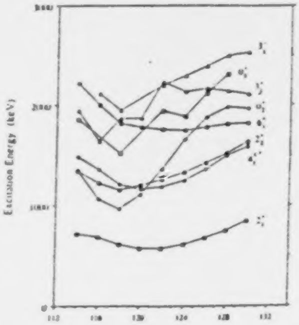

Figure 3. The mass dependence of selected energy levels in the Tellurium nuclei.

$$\mathcal{H} = \hbar\omega\, d_\pi^+ d_\pi + \hbar\omega\, d_\nu^+ d_\nu + KQ_\pi \cdot Q_\nu + V_{\nu\nu} + M_{\pi\nu} \qquad (1)$$

where the first two terms are readily recognizable as that of the standard simple harmonic oscillator. Protons and neutrons are distinguishable particles and thus there exists two types of phonons in the system; π (protons) and ν (neutrons), hence the name Interacting Boson Model-2. The phonon energy ħω is taken to have the same value for both types. Multiple phonon states are possible, forming degenerate states. If the nucleus is not spherically symmetric, these degeneracies will be broken. The remaining terms in the IBM-2 Hamiltonian have the effect of describing non-spherical vibrations. The third term is an interaction between the quadrupole moment of the protons and the quadrupole moment of the neutrons. The fourth term splits the degeneracy in the two-phonon multiplet. The last term serves to differentiate states which are symmetric or asymmetric under interchange of neutron and proton labels. The effects of the last term are not considered in this paper.

In the mid-neutron-shell Tellurium-120, the splittings between members of multiplets are reasonably small ($V_{\nu\nu} = 0$) which suggests that a spherical vibrational model would provide a good description of the nuclear properties. As one moves away from the mid-shell ^{120}Te, anharmonicities ($V_{\nu\nu}$) should grow as the nucleus becomes (γ-) softer and more prone to deformation. The 0_2^+ state should rapidly rise to join the 3_1^+ state. This is observed.

The explanations above are based only upon level energies. Often level energies are more important for evaluating whether a model has sufficient built-in complexity rather than distinguishing between alternate physical descriptions. Transition rate information is crucial to revealing the absolute amplitudes of particle and collective components in the wavefunctions. Selected transition rates for the tellurium nuclei are given in Table I.

Table I. Selected experimental transition rates. Values are given in Wu (Weisskopf units). Quadrupole moments are taken from Firestone (1996). Uncertainties given in parenthesis are those in the last digits.

Q (b)	-0.29	-0.21	-0.13	-0.05

The measured quadrupole moments observed are reasonably small (as expected for spherical nuclei), and increase when going toward the mid-shell ^{120}Te. The IBM-2 calculations naturally indicate a vibrational structure. The single-phonon component of a excited state's wave function is indicated by the strength of the E2 ground state transition. The 2_1^+ state has a strong single-phonon character with little single-phonon character in the higher 2^+ states. With the exception of the results for ^{128}Te, the 0_2^+, 2_1^+,4_1^+ triplet of states have reasonably strong decays into the single-phonon 2_1^+ state as is expected from a two-phonon excitation. The IBM-2 calculation is in fair agreement with the measured 2_1^+ --> 0_1^+ and 0_2^+ --> 2_1^+ transitions.

The tellurium nuclei will not provide information on the mixed symmetry states unique to the IBM-2 model. There are no anomalously large M1 transitions which are signatures of these mixed symmetry states. This is consistent with the IBM-2 model calculations which indicate that the mixed symmetry strength is spread over all the low lying 2^+ states.

Using the PCM model, Lopac (1970) has examined the level sequence in the telluriums as a function of the particle-to-phonon coupling strength. Near A=120-122 (mid-shell) the trends toward γ-soft deformation were reproduced using smaller particle-phonon coupling strength.

Degrieck (1974) repeated similar calculations and made predictions of a few M1 and E2 transition rates. Although his model parameters are based on refined experimental information in Sn, Sb, and Te, the mass behavior of the particle-phonon coupling strength appears diametrically opposed to that suggested by Lopac (1970). Degrieck's calculation reproduces the excitation energies of the 2_1^+, 4_1^+, and 6_1^+ states, all others are forced out of their "natural locations".

In both PCM model treatments, only 60-75% of the wave function is accounted for in terms a readily identifiable components; this is actually on par with most shell model calculations. Examination of the transition rates predicted by the Lopac and Degriek revealed the complete failure of both calculations. The simpler IBM-2 treatment produces more reliable explanations than these two "more advanced" PCM calculations.

Younes (1993) has re-examined the heavier Te isotopes through the PCM. The calculations indicate the 6_1^+ state has more single particle structure as one moves from lighter to heavier isotopes. This increasing particle-character for the higher spin states in heavier isotopes is consistent with the dropping of the $g_{7/2}$ and $h_{11/2}$ orbits suggested by the odd mass Z=51 (Sb) nuclei.

SUMMARY

The excited levels of ^{124}Te, ^{126}Te, ^{128}Te and ^{130}Te and the electromagnetic transitions between these levels have been studied using the (n,n'γ) reaction. Using a recently developed γ–γ coincidence technique, the level schemes were constructed up to approximately 2800 keV for each nucleus. Angular distributions and Doppler shifts were measured at an incident neutron energy of $E_n = 2600$ keV. This data allowed extraction of level spins, parities, and lifetimes of the states. Transition rates between levels were calculated for comparison to nuclear models. A standard IBM-2 treatment produced moderate agreement with measured level energies and transition rates. Two implementations of the more refined PCM treatment were completely unable to adequately describe these nuclei. The simpler IBM-2 treatment produces more reliable explanations than these two "more advanced" PCM calculations. An explanation of the nuclear structure of the 6_1^+ state remains elusive.

Faculty Advisor:

Dr. H. David Sheets

A mechanical system of coupled harmonic oscillators provides a practical simulation of a one-dimensional crystalline lattice. Using this system, the decay of a wave packet and the speed of sound in the physical lattice model were measured. This was done through the use of an ultrasonic position monitor and computer software to record the position of a lattice element as a function of time as a pulse moves through the lattice. We compare the observed experimental results with the theoretical predictions.

THEORY

The position of a particle, x_n, of a one-dimensional linear lattice of coupled springs and equal masses with fixed endpoints, is described by:

$$m(d^2x_n/dt^2) = f(x_{n+1} - x_n) - f(x_n - x_{n-1}) \qquad (1)$$

Let u_n be the separation between lattice points. Then

$$u_n = x_{n+1} - x_n . \qquad (2)$$

Rewriting equation (1) in terms of u_n:

$$m(d^2u_n/dt^2) = m(d^2x_{n+1}/dt^2) - m(d^2x_n/dt^2) = f(u_{n+1}) - 2f(u_n) + f(u_{n-1}) \qquad (3)$$

Assuming the force will be of the form of a linear spring force, then:

$$f(z) = -\mu z . \qquad (4)$$

where μ is the spring constant. To obtain the wave equations for the lattice, a change from a discrete to a continuous variable is necessary. Replacing this discrete model by a continuous one yields

$$u_n(t) = u(x,t) \qquad (5)$$

Following Jackson (Jackson, 1991), the Taylor series expansion of equation (5) becomes,

$$u_{n\pm1}(t) = u(x,t) \pm h(\partial u/\partial x) \pm (h^2/2!)(\partial^2u/\partial x^2) \pm \ldots \qquad (6)$$

Here h is the equilibrium separation between lattice elements. The solutions of the differential equation resulting from inserting (6) into (3) will be traveling waves, of the form

$$x = A(k) \sin(kx-\omega t) , \qquad (7)$$

where A(k) is dependent on the nature of the excitation and $\omega(k)$ must satisfy the dispersion relation:

$$\omega = 2 (\mu/m)^{1/2} \sin(kh/2) . \qquad (8)$$

In equation (8), ω is the angular frequency, μ is the linear spring constant, m is the mass of each lattice element (cart), k is the wave number, and h is the equilibrium separation between lattice elements.

Now that the dispersion relation is known the condition that a wave packet will break up in a lattice will be discussed. The pulse will travel at the "group velocity", v_{group}. The equation for v_{group} is:

$$v_{group} = (d\omega/dk)|_{ka} = h(\mu/m)^{1/2} \cos((ka)h/2) \tag{9}$$

where ka is the average k value of the traveling waves (equation 7) making up the pulse. (For a more complete derivation of the group velocity see Crawford, 1966). From equations (7), (8), and (9) it can be shown that a wave packet will break up if there is a variation in wave speeds in the packet over $\Delta\omega$, the range of frequencies making up the packet.

The theoretical breakup of the wave packet is as follows.
A minimum Gaussian packet has the property that:

$$\Delta\omega\, \Delta t_o \approx 1\ , \tag{10}$$

where Δt_o is the initial temporal width of the pulse. The spatial width, ΔL as a function of time, is given by:

$$\Delta L = \Delta v\, t = \Delta k(\partial v_g/\partial k)|_{ka}\, t = [\Delta k\ (\partial^2\omega/\partial k^2)|_{ka}]\ t\ , \tag{11}$$

where Δv is the variation in the velocities over the frequencies present in the wave packet, t is the time, and Δk is the range in wave numbers corresponding to $\Delta\omega$. The temporal width, Δt, is given by:

$$\Delta t = \Delta L/v_g = [\Delta k\ (\partial^2\omega/\partial k^2|_{ka})/v_g]\ t \tag{12}$$

If v_{group}, given by equation (9), is relatively constant over the range of k values then $\Delta\omega/\Delta k$ can be approximated by:

$$v_g = (d\omega/dk)|_{ka} \approx (\Delta\omega/\Delta k) \tag{13}$$

Substituting the solution obtained for Δk from equation (13) into equation (12) yields the following equation

$$\Delta t = [\Delta\omega\ (\partial^2\omega/\partial k^2|_{ka})/v_g^2]\ t \tag{14}$$

From equation (10) it can be shown that equation (14) can be written as:

$$\Delta t = [\partial^2\omega/\partial k^2|_{ka}/(\Delta t_o\, v_g^2)]\ t \tag{15}$$

The temporal width of the pulse increases linearly with time.

EXPERIMENT

An air track was set up with twelve individual lattice elements (carts) coupled together by springs. The average mass of the carts was 0.3 kilograms and the average spring constant was 26 N/m. The carts were set in motion from one side by using a magnetic solenoid pulser. The data recording system was triggered by this pulse. The position of each of the carts was obtained by use of an ultrasonic sensor, Migatron Corporation RPS-401A-40 (Cascio and Sheets, 1995). The sensor works by sending out an ultrasonic signal, which bounces off the cart and returns to the sensor, at which point a voltage is assigned to the distance of the cart and converted to digital data which the computer records at a sampling frequency of 70 Hz. All data was manipulated and interpreted using the student version of Matlab and QBASIC.

To experimentally find the dispersion relation, the following procedure was used. First, a pulse was sent through the lattice and the resulting motion was recorded over a 50 second time interval. A Fast Fourier Transform was then performed on the data to extract the resonant frequencies of the lattice (Runk, Stull, and Anderson, 1963, or Cascio and Sheets, 1995). These resonant frequencies were then matched with their corresponding modes of oscillation to generate the dispersion curve, ω versus k. Figure 1 shows this graph which corresponds to equation (8).

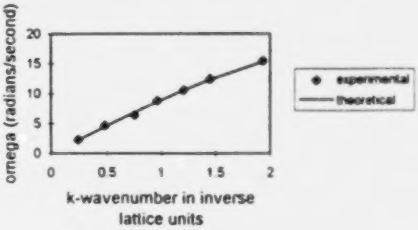

Figure 1: Dispersion curve for the system

The group velocity was then determined. The arrival of the pulse was measured at each of the lattice sites, then the pulse shape at each of the lattice sites was graphed. The full width at half maximum was calculated from each of these pulse shapes. Only the first eight lattice sites were used, as the pulse shape was distorted by waves reflected off the end of the lattice for the ninth through twelfth carts. The time for the peak excursion to reach each of the lattice sites was calculated from the experimental data, where the peak excursion corresponds to the time when the 'middle' of the wave packet reaches each of the lattice sites. From the arrival time of the peak excursion the group velocity of the wave packet can be experimentally calculated. The slope of the lattice distance against the elapsed time yields the group velocity. Figure 2a shows the graph of the lattice distance as a function of time, and Figure 2b shows a typical pulse shape measured at one of the lattice sites.

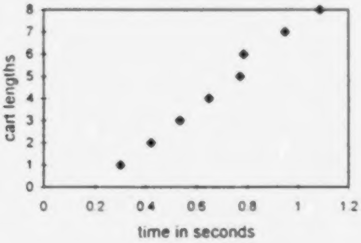

Figure 2a: Lattice distance vs elapsed time

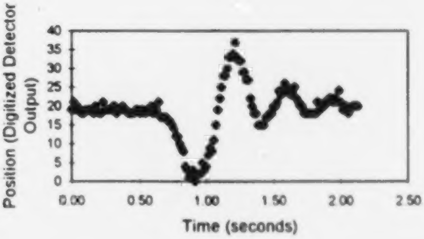

Figure 2b: Typical Pulse Shape

The numerical value of slope of the line of Figure 2a was found to be 9 lattice sites per second. This corresponds to an experimentally calculated group velocity or speed of sound of 9 lattice sites per second. From the group velocity the velocity of the pulse was obtained, since the velocity of the pulse is the group velocity evaluated at the average k value. The average k value was obtained by substituting the experimentally derived group velocity into equation (9) and solving for k_{ave}. The value of h was taken to be 1 since the group velocity was obtained in terms of lattice sites per second. From this k_{ave} was found to be 0.6 (lattice units)$^{-1}$.

The full width at half maximum (FWHM) was measured directly from the graph of the pulse shape at each lattice sites. The FWHM was then graphed against the arrival time of the peak of the pulse at each of the lattice sites. Figure 3 shows the measured FWHM versus arrival time, and the predicted FWHM from equation (15) versus arrival time.

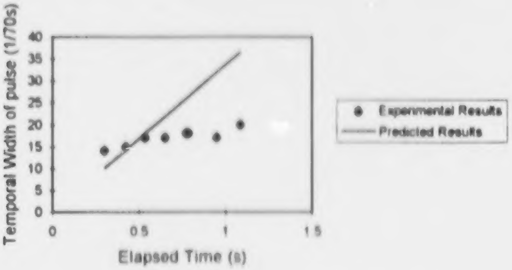

Figure 3. Predicted and Observed FWHM of Pulse

CONCLUSION

From Figures 1 and 2a it can be seen that the dispersion and the group velocity are consistent with the theory. Figure 3 shows that the pulse breaks up, but not at the rate predicted by the theory. The simple theory used was not sufficient to model the system studied. A more plausible theory could contain terms connected to friction, air drag on the cart, or variations in the k values. If this is the case, questions about the amount of friction needed to match the measured results, or how much variation in the k values would be required to match the measured results would have to be answered. Further research will involve experimentation with friction in the lattice, such as a magnetic frictional force in the physical lattice. Another approach is to observe the rate of pulse breakup as a function of the initial temporal width, Δt_0. A computer simulation will be done to test the amount of friction or variation in the k values needed to obtain the observed results.

Dr. Zolili Ndlela

A knowledge of strain measurement is extremely important for the evaluation of civil and military structures (especially for new composite materials used in airplanes). The strain gauge is commonly used to perform such measurements. We investigate an alternative method of measuring strain using optical fiber sensors. Optical fibers have some physical and technical properties that offer some advantages over strain gauge technology.

In this investigation, a Fabry-Perot fiber optic interferometer is used to measure the strain in a vibrating aluminum beam. A data acquisition system was built using LABVIEW™ to acquire and analyze, in real time, data from the interferometer. Strain measurements with the fiber optic interferometer compared favorably with a conventional strain gauge and theoretical values.

INTRODUCTION

Strain in materials and reproducible structures is measured using strain gauges. Although strain gauge technology is well understood and this method for measuring strain yields fairly accurate results, other technologies such as fiber optic sensors can offer some competetive advantages. We investigate an alternative method to measure strain using optical fibers. We believe this method when fully developed can provide a more accurate and efficient way of measuring strain. The on site measurements of strain are often transmitted to the central processing unit as electrical signals over metallic (usually copper) wires. The proposed approach transfers the strain measurement from the site to the central processing unit as optical signals using optical fibers. This approach has many distinct advantages. Optical fibers are low-cost, and are able to carry large amounts of information over long distances.

Optical fibers also have many physical properties that make them desirable. Optical fibers are generally non-corosive and light weight. Optical fibers have more appeal in areas where space, weight, and hazardous environments are issues. Because optical fibers are usually made from glass, which is a dielectric material, they are unaffected by electromagnetic interference. This is an advantage over copper in places where extra shielding might be necessary to yield accurate results.

Fiber transmitted signals may be easily multiplexed using a variety of methods. Multiplexing is already being implemented in phone lines. When applied to measuring devices such as a strain gauge, the technology of multiplexing of signals allows one to make a large number of local measurements.

BACKGROUND

The basis for the measurement of strain in the present approach is the phenomenon of interference of light waves[1]. Two light beams, obtained from a single coherent light source (a Helium-Neon laser) are brought together after having traveled different path lengths. Dark or bright fringes result depending on the difference in their path lengths.

Minute changes, on the order of a wavelength of light (632 8 nm in the case of the Helium-Neon laser) can be measured in terms of the number of fringes that move past a fixed point of reference[2,3] In other words, change in distances of about 0 6328 μm could be detected

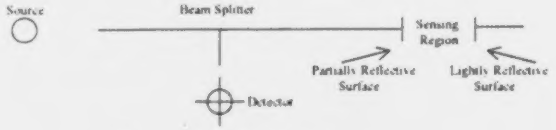

Figure 1 - Fabry-Perot Interferometer

We use the Fabry-Perot interferometer, Figure 1, in our investigation The Fabry-Perot Interferometer has a sensing region composed of the ends of fibers with partially and lightly reflecting surfaces A change in the environment of the sensing region such as an increase in strain, produces a change in the path length The increase in path length causes a shift in the fringe pattern of the interfering beams The number of fringes that shift during the changes in optical path lengths introduced by the strain is counted using a solid state photo detector In our set up the strain in an aluminum beam is measured A Fabry-Perot interferometer is expoxied onto the aluminum beam along side a conventional strain gauge The bending of beam caused by stress results in a change in the path length of the interfering beams Thus we measure the strain caused by the stress

THEORETICAL BACKGROUND

Bending of a Mechanical Beam

We assume that the bending of the beam is uniform Figure 2 defines the coordinate system and the relevant parameters of a uniformly bent mechanical beam We assume small amplitude bending for the following discussion

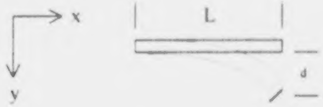

Figure 2 - Mechanical Beam

The deflection d is given by[4]

$$d = \frac{FL^3}{3EI}, \qquad (1)$$

where,
F = applied force
E = Young's modulus
I = area moment of inertia about z – axis

The longitudinal strain ε_x is given by[4]

$$\varepsilon_x = \frac{F(L-x)\left(\frac{t}{2}\right)}{EI} \qquad (2)$$

Substituting (1) in this expression yields

$$\varepsilon_s = \frac{3}{2}\frac{d(L-x)}{L^3}t, \qquad (3)$$

where d is the deflection, L is the total length of the beam, x is the distance fixed end of the aluminum beam to the fiber, and t is the thickness of the beam

Interference

The phase difference ϕ, between the two interfering laser beams is given by

$$\phi = (2nL_g)k \qquad (4)$$

$$\frac{\Delta\phi}{\phi} = \frac{\Delta L_g}{L_g}, \qquad (5)$$

where n is the refractive index of the fiber, L_g is the gauge length of the fiber, and k is the wave vector of the laser light.

We assume that bending of the fiber does not introduce any significant changes in its refractive index. In addition, the temperature of the equipment and surroundings were constant throughout the experiment.

SET-UP

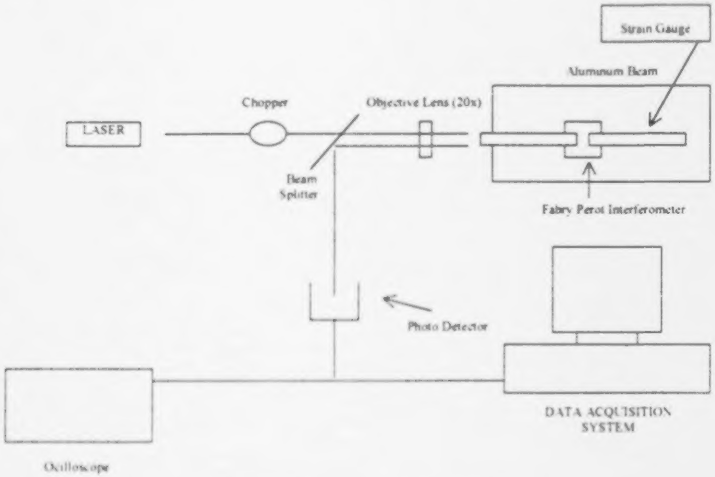

Figure 3 - Set-up used in Investigation

A Helium-Neon laser (λ = 632.8 nm) was used as the coherent light source. The beam is chopped to enhance the signal amplitude. The beam was split into two nearly equal intensity parts using a 50% reflective beam splitter. One beam, after focusing, was sent into the Fabry-Perot Interferometer, bonded by epoxy to the aluminum beam. This beam was reflected off of the partially reflective surfaces of the interferomenter and then interfered with the second beam. The resulting inteference pattern was detected by a solid state photo detector. The photo detector converted the light signal into an electrical signal. The electrical signal coming from the photo detector was monitored in real-time by the ocilloscope and data was stored by the Data Acquisition System that was built using LABVIEW[a].

RESULTS AND CONCLUSIONS

The apparatus and set-up used in the present investigation is shown above in Figure 3. The data was displayed both by the ocilloscope and the LABVIEW® data acquisition system. A controlled amount of stress was put on the aluminum beam by a translation stage that was mounted just above the aluminum beam.

The photo detector which detects the maximum (bright fringes) and minimum (dark fringes), sends an electrical signal to the data acquisition system and the ocilloscope.

The values were stored and then analyzed. The value of strainwas determined for the aluminum beam. This measurement of strain was compared with the measurement reading on the strain gauge.

Table 1 - *Key Parameter Measured Values*

L	Total Length of Aluminum Beam	**464.5 mm**
L_g	Gauge Length	**2.25 mm**
t	Thickness of Aluminum Beam	**2.50 mm**
x	Distance from Fixed end of Aluminum Beam to the Fiber	**109.8 mm**
$L-x$	Distance inbetween fiber and point of pressure	**354.7 mm**
n	Refractive index of fiber	**1.465**

The theoretical value calculated for strain with a deflection of 6.968 mm is

$$\varepsilon_s = \frac{3}{2} d \frac{(L-x)}{L^3} t = 92.48 \times 10^{-6} = 92.48 \mu\varepsilon$$

The experimental value calculated using equation (4) is

$$\Delta L_g = \frac{\lambda}{2}$$

$$\frac{\Delta L_g}{L_g} = \frac{\lambda}{2nL_g} = 95.99 \mu\varepsilon$$

These preliminary results show a close agreement between theory and experiment. The small difference between the theoretical and experimental values could be caused by low precision distance measurements. We plan to improve upon the present measurement accuracy in the next phase of research.

ACKNOWLEDGEMENTS

The author wishes to express his deep appreciation to Dr. Zolili Ndlela, for his guidence and help in this investigation.

Grambling LA 71245)

Transition metals cobalt and copper play significant roles in the conversion of syngas (CO + H_2) to liquid fuels. With a view to examine the nature of interaction between CO and metal, the FTIR spectra of CO adsorbed on Co-Cr_2O_3 composites were investigated. The results indicate that as cobalt loading increases, the intensity of the CO adsorption bands increase and several vibrational modes seem to be promoted. Heat treatment of the sample revealed two distinct processes of adsorption. Bands due to physisorption disappeared while bands due to chemisorption not only increased in intensity but persisted even after desorption. It seems that the physisorption process is more active when the catalyst is fresh and is hindered when carbidic/carbonyl formations occur on the metal surfaces.

INTRODUCTION

The study of CO adsorption on Co-Cr_2O_3 alloy by infra-red spectroscopy and magnetic methods is of interest for various reasons.

(i) A complete description of gas-metal interactions requires information on both the adsorbate and the absorbent, and this can be achieved by using simultaneously these two techniques.
(ii) CO is a good probe molecule for chemisorption studies because of its associative or dissociative nature when adsorbed on metal. This study could provide information on the electron charge transfer mechanism of the probe molecule.
(iii) Magnetization studies provide information on the changes in the metallic charge distribution character of the composite sample.

Very little work [Mohana Rao, 1988; Sato, 1984] has been done on infrared spectra of carbon monoxide adsorbed on cobalt. To our knowledge no FTIR studies of CO adsorption on Co-Cr_2O_3 have been made nor any correlation results reported between magnetization and FTIR data. This paper presents the results of the magnetic and FTIR measurements on Co-Cr_2O_3 metal composite.

1362

EXPERIMENTAL METHODS

Magnetic measurements of the composite sample were made using a Digital Measurement Systems (Boston, MA) DMS-880 vibrating sample magnetometer and Zero-field NMR spectra were obtained using a modified WILK's NQR spectrometer described else where [Murty, 1988].

The FTIR Spectrometer and DRIFT System consists of Mattison Research series FTIR spectrometer, equipped with an MCT detector operable in the mid IR region (4000-600 cm^{-1}), a diffuse reflectance accessory, an environmental chamber and an automatic temperature controller.

An optical diagram of the diffuse reflection attachment is shown in Figure 1. The praying mantis design incorporates two 6:1 90° off -axis ellipsoidal mirrors, M_3 and M_4, which subtend 20% of the 2 pi solid angle. These ellipsoids are arranged with a common focal point S. Mirrors M_1 and M_2 transfer the IR beam from the spectrometer to the first of these ellipsoids M_3. This ellipsoid focuses the beam onto the sample, S. The second ellipsoid collects the radiation diffusely reflected from the sample. This radiation is then directed by mirrors M_5 and M_6 towards the detector. The environmental chamber (Figure 2), a stainless steel reaction chamber, consists of a sample cup to load the sample, two windows at the entrance and exit positions for the incident and reflected infrared radiations. A third window is provided at the back of the chamber to illuminate or view the sample. In addition two entry ports are provided for vacuum and gas and another set for water circulation. The environmental chamber is connected to an automatic temperature controller that can be raised up to 600°C.

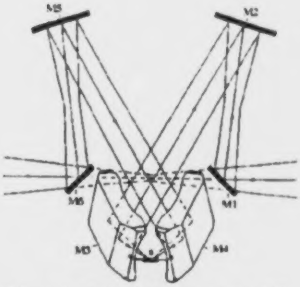

Figure 1 Optical Arrangement of the DRIFT System

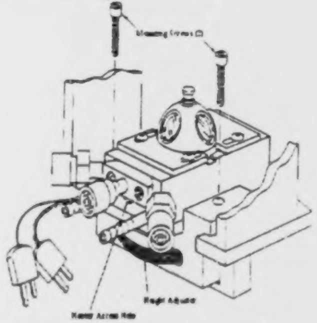

Figure 2 Environmental Chamber

Sample preparation:

All the samples were prepared by co-precipitation of nitrates in a 7-8 pH sodium hydroxide solution at 80°C. The precipitate is washed, dried at 80°C for 18 hours, calcined at 350°C for 18 hours and reduced in a flowing stream of hydrogen at 350°C for 18 hours. Hydrogen was out gassed while reducing the temperature to 250°C. At this temperature carbon monoxide was admitted for 30 minutes and then while continuously flowing carbon monoxide the temperature was reduced step wise to 25°C and spectra were taken at each temperature. At 25°C CO was out gassed and the temperature was increased in reverse order to obtain the desorbed spectra of CO. Four different samples ($0.5 < Co/Cr < 16.0$) were used in this investigation to study the effect of metal ratio on the CO stretching frequencies. FTIR spectra for each sample were taken three times for reproducibility of the results. All the spectra obtained were recorded with 500 scan accumulation at a resolution of 4 cm^{-1}.

RESULTS AND DISCUSSION

Magnetization studies made on three samples $Co/Cr \leq 2.0$ indicate that about 75% of cobalt is locked in $Co\text{-}Cr_2O_4$ type spinel structures. Only 25% of the loaded metal appears to be amenable for reduction. NMR spectra did not reveal any inter-metallic interaction between cobalt and chromium. NMR lines occurred in the expected positions for pure cobalt [Murty, 1991].

FTIR results are presented in Table 1 and Figures 3-5. Frequency measurements are accurate within ± 4 cm^{-1}.

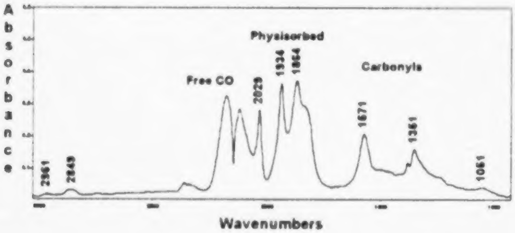

Figure 3 Co/Cr (16.0) + CO @250^{0}C

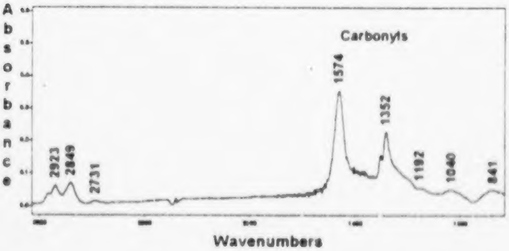

Figure 4 Co/Cr (16.0) CO Desorbed @ 250^{0}C

In all the spectra recorded we did not observe any significant changes due to temperature variation.

The observed spectra fall in to three distinct regions.

A. 2900 - 2750 cm^{-1} B. 2000 - 1650 cm^{-1} C. 1600 -850 cm^{-1}

PA- Physisorbed Bands Weakly Bonded to Metallic Co

The two sharp peaks (Figure 3) at 2170 and 2117 (P and R branch heads of 2143cm^{-1} of CO band) are due to free gaseous CO molecule. The bands in the region 2000 - 1650 cm^{-1} region seem to be due to CO linearly bonded to Cobalt [Hollins]. Desorption of CO causes the disappearance of these bands. Figures 3 and 4 clearly illustrate this effect of CO-desorption. These lines could be due to physisorption processes ranging from weak electrostatic interaction to bonding with one, two, or three surface cobalt metal atoms. The physisorbed bands seems to be dependent on temperature, metal ratio and the time of CO flow. The bands in the 1600 - 850 cm^{-1} region are persistent even after desorption of CO. This might be, as suggested by earlier investigators (Little [2], Nakamoto [6]) due to the formation of CO_2 which is stabilized in the matrix as a CO_3^{2-} species. The bands in the region 2900 - 2750 cm^{-1} are also persistent after desorption and may result due to different chemical interactions between CO and Co-Cr_2O_3 matrix. We noticed that carbonyls formation takes plece when the catalyst is exposed to CO even at room temperature. Though this retards physisorption process, deactivation of the catalyst may not occur and the metal carbonyls formed might play active roles in the catalytic process.

The 1600 cm^{-1} band seems to be sensitive to the metal ratio and shows a downward trend as Co content increases up to a certain point. Further increase of Co metal in the sample Co/Cr = 16.0, this band became sharper and more intense and shifted back to higher wavenumbers (Figure 5). It is difficult to ascertain whether it is a frequency shift in the stretching frequency of a a specific carbonyl band or different carbonyl structures occur as more cobalt appears in the matrix. Metal ratio appears to have no significant effect on the other bands in this region.

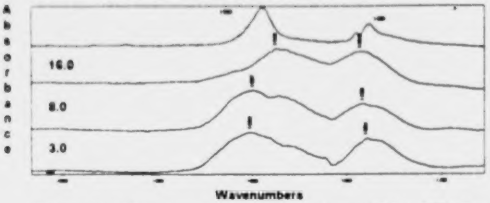

Figure 5 FTIR Spectra: Comparison of Metal Ratios @ 25°C

CONCLUSIONS

Our NMR studies show no noticeable shift in the NMR lines of cobalt indicating that no significant intermetallic interactions occur between metal and support. Magnetization studies indicate that at lower metal loading Co/Cr ≤ 2, most of the cobalt could be locked in spinel structures and only the metal appears to be amenable for reduction. IR spectra on all the samples studied ($0.5 < Co/Cr < 16.0$) show no measureable changes due to temperature variation either in the absorption or desorption process. At low Co ratios physisorption bands formed could be due to weak linear CO - metal bonding. Increase in cobalt metal content seems to enhance the physisorption process and CO bonding might be occurring with multiple surface metal atoms. In all the samples studied we have observed metal carbonyl bands indicating that a chemical reaction occurs and CO_2 formed may be stabilized in the matrix as CO_3^{2-} species. Further studies might provide better insights into the catalytic mechanisms involved.

Organic-based solar cells have been shown to be a promising clean, regenerating, and inexpensive energy source. Research into the Grätzel-style solar energy conversion cell has focused on several classes of water soluble, osmium and ruthenium-based photosensitizers absorbed onto titanium dioxide(TiO_2) thin films[1,2]. These dyes absorb in the visible portion of the solar spectrum and have limited light fast properties, which compromises the design and overall efficiency of the cell. The film is composed of nanostructured, TiO_2 particles with a high degree of surface roughness, increasing the surface area of the film and providing more area for the TiO_2/sensitizer interface.

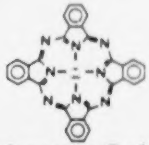
In order to enhance the efficiency and the stability of the solar cell, we are investigating the use of photosensitive pigments, such as phthalocyannines, that absorb in the visible and infrared and have excellent light fast properties. Using Lewis Acid Pigment Solublization(LAPS), cells can be easily sensitized to a wide variety of photosensitive pigments. Application of a LAPS solution of hydroxygallium phthalocyannine to nanostructured TiO_2 thin films has achieved a maximum open circuit voltage of 0.347 Volts, a closed circuit current of 0.0188 mA/cm^2 under an irradiance of 0.726 W/m^2 with a conversion efficiency of 9.0% .

INTRODUCTION

The desire for a cheap, environmentally friendly source of energy has renewed interest in solar energy conversion. Despite their commercial availability, expense has limited the general appeal of silicon-based solar cells[3]. Recent research into photosensitized, nanocrystalline titanium dioxide thin film solar cells, pioneered by Dr. Michael Grätzel of the Swiss Federal Institute of Technology, has resulted in comparable conversion efficiencies at a significantly lower cost than conventional silicon-based solar cells. The cells are sensitized with Cis-dithiocyananto-N-bis(2,2'-bipryidyl-4,4'-dicarboxylic acid) ruthenium(II) dihydrate, ($[RuL_2(NCS)_2]\cdot 2H_2O$), a water soluble dye. These Grätzel-cells primarily absorb in the visible portion of the spectrum, have produced a current of 12 mA/cm^2 and conversion efficiency of 12% in natural sunlight. Much research has focused into extending the sensitivity of the photosensitizers into the infrared to increase the conversion efficiency of the Grätzel -style solar cell[4].

Kajihara *et. al.* recently demonstrated energy conversion using vacuum deposited zinc phthalocyannine on TiO_2 and ITO[5]. Phthalocyannine pigments, which are both visible and infrared sensitive, would extend the spectral sensitivity of the Grätzel -cell into longer wavelengths. The main phthalocyannine thin film fabrication method to date, vacuum deposition, is, however, an expensive procedure relative to the dye-soak method employed by Grätzel and would increase the costs of these devices.

Using Lewis Acid Pigment Solublization(LAPS) allows for solutions of previously insoluble photosensitizers, including phthalocyannine pigments, and thin film production at a relatively low cost. Prior to this, phthalocyannine thin films were primarily manufactured with vacuum deposition[6]. The LAPS method has allowed for the use of phthalocyannine pigments to construct nanocrystalline solar cells without sacrificing the overall cost of the cell. Since phthalocyannine's are sensitive primarily from the red wavelengths of the visible into the infrared, phthalocyannines absorption will closely match the actual spectral characteristics of the sun. In addition, since these pigments are insoluble to nearly all common solvents, substitution of acetonitrile in the electrolyte with a different solvent that would allow for easier sealing may eliminate the need for advanced sealants[7].



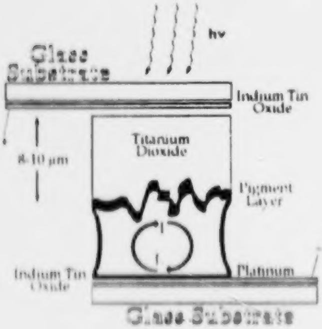
Phthalocyannine (Pc) Ligand

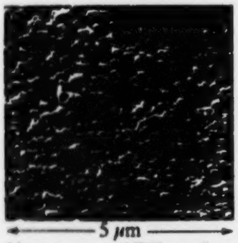
EXPERIMENT

Production of the phthalocyannine sensitized solar cells follows closely the methods used by A. Hagfeldt, et al[7]. A colloidal solution of 12.0 g TiO_2, 20 mL water, 0.2 mL acetylacetone, and 0.1 mL Triton X-100 is ball milled overnight to produce nanoparticles of

BEST COPY AVAILABLE

TiO_2 in solution. An 8 to 10 µm film is spun onto a 10 Ω/☐ Indium-Tin Oxide(ITO) coated substrate and then annealed at 450 °C under nitrogen for one hour.





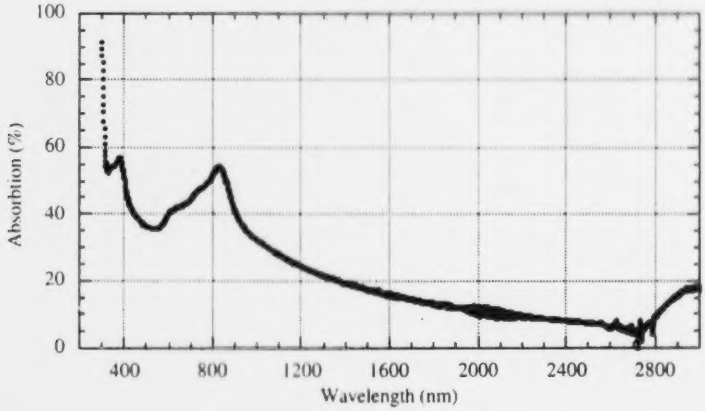
Nanostructured TiO_2 surface

The ITO-TiO_2 substrate is immediately removed from the oven and placed into a LAPS-pigment solution for four hours. The LAPS-pigment solution is produced by mixing a 6:1 ratio of aluminum chloride($AlCl_3$) atoms to hydroxygallium phthalocyannine(HOGaPc) in at least 50 mL nitromethane per gram of $AlCl_3$ for one hour on a magnetic stirring plate.

The ITO-TiO_2 coated substrate is allowed to soak for four hours to photosensitize the thin film with HOGaPc and then rinsied with water to remove the $AlCl_3$ from the cell. A second platinum/ITO substrate, coated in a dilute solution of hydrogen hexachloroplatinate under 5 mA of current for three seconds, forms the counterelectrode for the solar cell.

Approximately 0.5 mL of a solution of 0.3 mM I_2 and 0.3 M LiI in acetonitrile is placed on top of the ITO-TiO_2-HOGaPc substrate and then covered with the second, platinum-coated ITO substrate. The acetonitrile prevented any attempt to seal the cell with hot glue, since the solvent prevented the glue from adhering. A solution of 0.3 mM I_2 and 0.3 M LiI in water was also prepared and tested on solar cells to study the effects on cell sealing.

A silver conducting epoxy forms the electrical contact with the ITO substrate, completing the circuit. The cell was irradiated with 0.726 W/m^2 from a 150 W tungsten bulb in an integrating sphere.

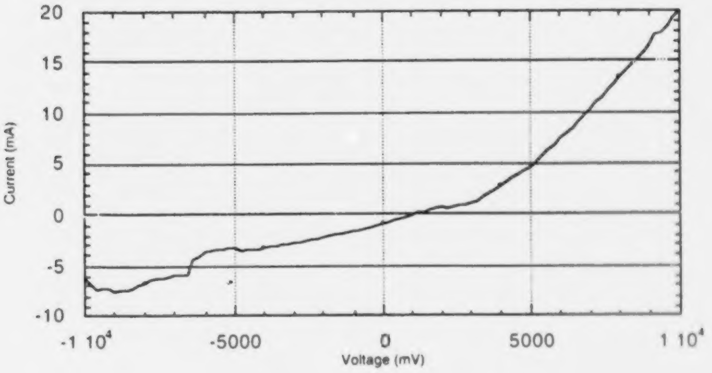


Absorption of HOGaPc on Quartz

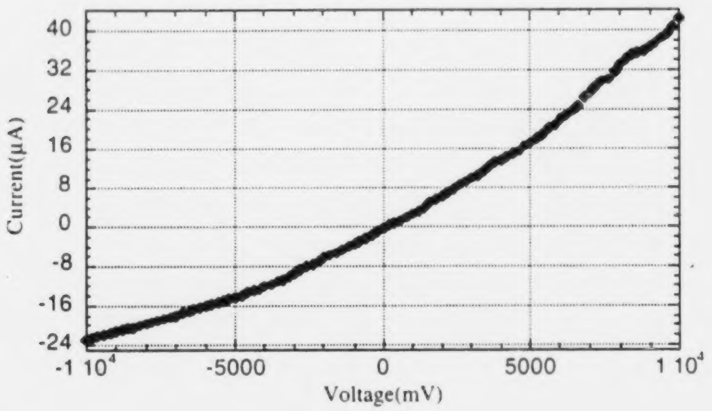
RESULTS

The absorption of the HOGaPc on quartz was measured using a Perkin-Elmer spectrometer and is plotted above. Absorption of HOGaPc is strongest in the visible and infrared. It is not expected that different phthalocyannines should have significantly different absorption characteristics than HOGaPc[9].

The demonstrated cell efficiencies of 9.0% were achieved using a tungsten filament. The cell was irradiated with 0.726 W/m^2 , and produced an short circuit current of 0. 0188 mA/cm^2, and an open circuit voltage of 0.347 V. The current- voltage characteristics for both illuminated and for dark cells are plotted here. The dark current is nearly three orders of magnitude lower than the corresponding cell under illumination.



Characteristics of HOGaPc
Sensitized Cell with Illumination



Dark Characteristics of HOGaPc
Sensitized Cell

Substitution of a similar solution of I_3 /I in water to that of the solution in acetonitrile provided for a cell that could be sealed with hot glue, and did not measurably reduce cell efficiency. Long term stability tests with water-based electrolyte solutions have not been attempted, but intact hot glue seals on the cells have lasted at least several hours, an improvement over similar cells with acetonitrile, where hot glue sealing was not possible.

CONCLUSIONS

Lewis Acid Pigment Solublization provides an effective means of photosensitizing titanium dioxide based photoelectrochemical solar cells. Open circuit voltages of 0.347 V and short circuit currents of 0.0188 mA/cm^2 corresponding to a conversion efficiency of 9.0% were observed with hydroxygallium phthalocyannine sensitized under illumination by 0.726 W/m^2 from a tungsten filament. Phthalocyannine solutions from the Lewis Acid Pigment Solublization process provide for an effective, inexpensive way of photosensitizing Grätzel - cells. Elimination of water soluble dye's also provides for a possible inexpensive sealing method for cells, since solvents such as acetonitrile, which were the primary limiting factor to sealing a dye-based cell, are no longer necessary.

James F. Kasting

In the past year, several stellar planetary systems have been discovered. Planets of Jovian mass have been detected around stars suggesting that these or other planetary systems may also contain terrestrial planets. A space-based interferometer project has been proposed as a new detection method that is sensitive enough to discover terrestrial planets. The space-based interferometer would first detect these terrestrial planets through their radiated heat and then spectroscopically analyze them in the same spectral range (the thermal infrared, 7μm - 17μm). This research focuses on how one might eventually evaluate the spectroscopic data returned to Earth. If other Earth-like planets do indeed exist, the interferometer should be able to detect the spectral signatures of H_2O, CO_2, and O_3. Of these, O_3 is the most interesting because it is formed photochemically from O_2, and O_2 is almost exclusively a byproduct of the biological process of photosynthesis. This research is aimed at calculating the expected strength of the O_3 9.6 μm band as a function of atmospheric O_2 level on a planet like Earth. By inverting these results, it may ultimately be possible to infer atmospheric O_2 levels on extrasolar planets and to determine if they harbor terrestrial-type life.

BACKGROUND

In the past year, several extrasolar planetary systems have been discovered. Planets of Jovian mass have been detected around nine different, main sequence stars, suggesting the possibility that these or other planetary systems contain terrestrial planets. Until now, these new planets have been detected by ground-based telescopes by measuring the reaction motions of the stars they orbit. This method can detect giant planets, but it is not sensitive enough to detect less massive terrestrial planets. The physical conditions present on a particular extrasolar planet, including atmospheric composition, can, in principle, be measured by infrared spectroscopy. Based on this knowledge and the need for a new detection method that is sensitive enough to discover terrestrial planets, an idea has been proposed of utilizing a space-based interferometer (Angel and Woolf, 1996). The space-based interferometer would first detect these terrestrial planets through their radiated heat and then spectroscopically analyze them in the same infrared spectral range. This research focuses on the determination of a method that could be used once this space-based interferometer is operational to evaluate the spectroscopic data returned to Earth. Through this evaluation method the atmospheric oxygen concentration of the extra-solar planet and thus its life sustaining probability could be determined.

METHOD

In the infrared spectrum, the Earth uniquely shows ozone at the 9.6 μm band. This is of interest because ozone is formed from oxygen and oxygen originates from photosynthesis. Detection of oxygen on a terrestrial planet within an extrasolar planetary system would be of great interest since it would show that the planet could support life. To successfully use the results returned from the space-based interferometer, it is necessary to determine the ozone concentration and temperature as a function of atmospheric oxygen concentration on an Earth-like planet. The Chapman mechanism is one example of the relationship between oxygen production and ozone via the reactions:

$$O_2 + h\nu \rightarrow O + O \quad (\lambda \leq 200 \text{ nm})$$
$$O + O_2 + M \rightarrow O_3 + M \quad \text{(M is a random molecule)}$$

$$O_3 + h\nu \rightarrow O_2 + O \quad (\lambda \leq 700 \text{ nm})$$
$$O + O_3 \rightarrow 2O_2$$

The model used in this study also includes many other reactions that cause the catalytic destruction of ozone by HO_x, NO_x, and Cl_x.

To make this calculation, a coupled photochemical/radiative transfer model was used. By decreasing the oxygen concentration from the present atmospheric level of .21 to $.21 \times 10^{-5}$ within the photochemical model, the profiles of temperature and ozone concentrations for various atmospheric oxygen concentrations were determined for an earth-like planet.

MODEL DESCRIPTION

The calculations of surface temperatures were performed utilizing a one-dimensional radiative-convective model developed previously (Kasting et al., 1984; Kasting and Ackerman 1986). Originally, the atmospheric composition was assumed to be that of present Earth: 78% N_2, 21% O_2, 1% ^{40}Ar, and 330 parts per million CO_2 with a total surface pressure (excluding H_2O) of 1 bar. The radiative-convective model is based on a steady state method, which uses Newton's method to achieve convergence. The stratosphere was assumed to be in radiative equilibrium, and the troposphere was convectively linked using the moist adiabatic lapse rate. The boundary between these regions moved up or down as individual layers became convectively stable or unstable.

The photochemical model used for this study is an expanded version of a model used previously to simulate possible primitive terrestrial atmospheres (Kasting, 1985). Combined vertical transport and continuity equations are solved for 20 different species: O, O_2, O_3, H, OH, HO_2, H_2O_2, H_2, H_2O, CO, H_2CO, CH_4, CH_3O_2, CH_3OOH, N_2O, NO, NO_2, HNO_2, HNO_3, and HO_2NO_2. Seven additional species, including $O(^1D)$, $N(^4S)$, $^1CH_2$, $^3CH_2$, CH_3, HCO, and H_3CO, were assumed to be in photochemical equilibrium at each height step. A CO_2 mixing ratio of 340 parts per million was assumed in all cases. The numerical grid of the model extended from the ground up to 64 km in 1-km increments. The equations were solved using an implicit, time-stepping routine based on the reverse Euler method (Dahlquist and Bjorck, 1974). Zero flux was assumed for most species at the upper boundary. An upward flux of CO_2 required to balance photodissociation was assumed to be balanced by equivalent downward fluxes of CO and O. At the lower boundary, constant deposition velocities were assumed for the more reactive species O, H, OH, H, H_2O, CH_3O_2, HNO_2, HNO_3, HO_2NO_2, NO, NO_2, O_3, H_2O_2, H_2CO, and CH_3OOH. In the standard, present-day model atmosphere the volume mixing ratios of relatively long-lived species (CO, CH_4, N_2O, CH_3Cl, and H_2) were fixed at their observed global mean values (Logan et al, 1981 and Crutzen and Schmailzl, 1983). At lower O_2 levels, we assumed constant upward fluxes for these species, corresponding to those calculated in the standard model.

RESULTS

Ozone mixing profiles for atmospheres containing from 10^{-5} to 1 PAL (Present Atmospheric Level) of oxygen are shown in Figure 1. At O_2 levels below 1 PAL, the peak ozone

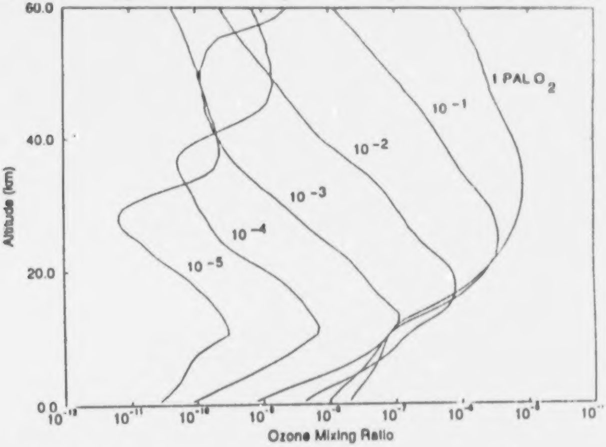

Figure 1 Ozone Mixing Profiles

mixing ratio decreases in magnitude and moves downwards in the atmosphere as a result of the increased depth of penetration of the solar ultraviolet radiation. At 10^{-1} PAL and below, the peak ozone mixing ratio is found at approximately 10 km. This corresponds to the height of the tropopause in our model. This peak in ozone is prevented from moving still lower by the presence of abundant hydrogen oxides that result from the rapid photolysis of water vapor in the troposphere. The maximum ozone mixing ratio occurs at 1 PAL of O_2.

The ozone column depth that corresponds to these profiles is shown in Figure 2. The ozone column depth increases monotonically with oxygen content. As this figure shows, the ozone column depth values that were found by this study closely resemble the values found by Kasting et al. (1985). The observed present global mean column depth of 320 D.U. (Dobson Units) (McClatchey et al., 1971) is within 5% of our calculated value at 1 PAL. The column depth at the equatorial region varies from about 250 D.U. to about 270 D.U. in an annual cycle. For Figure 2, a mean value of 260 D.U. was used for the equatorial column depth. As Figure 2 shows, the predicted global average ozone column depth exceeds the modern equatorial value for O_2 levels ≥ 0.2 PAL. Because modern organisms can unquestionably survive UV exposure under these conditions, we conclude that a biologically effective ozone screen was almost certainly established by the time atmospheric O_2 reached this level. Kasting (1987) concluded that UV shielding was probably effective at a lower O_2 level, ~ 10^{-2} PAL, based on previous Kasting et al. (1985) results. Since our results are not much different, this conclusion remains unchanged.

Figure 3 shows temperature profiles of atmospheres containing from 10^{-5} to 1 PAL of O_2.

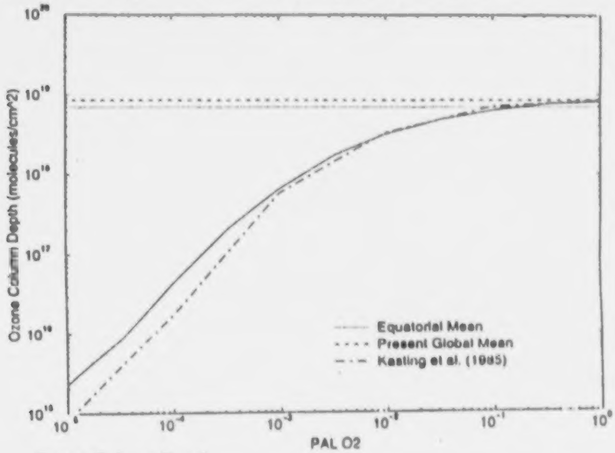

Figure 2 Ozone Column Depth

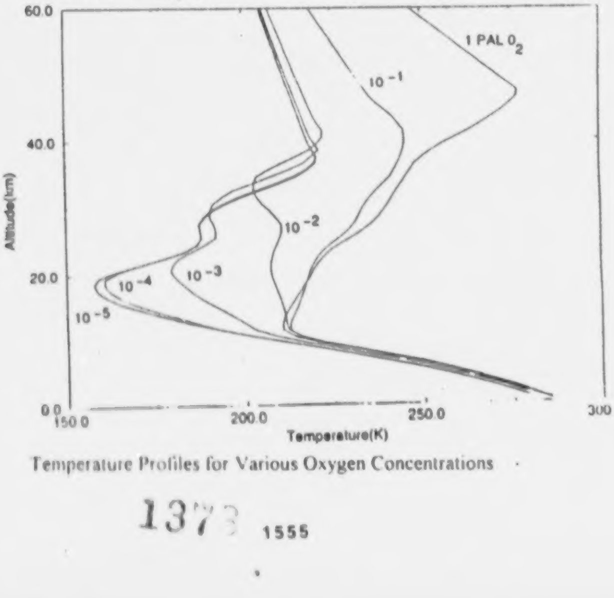

Figure 3 Temperature Profiles for Various Oxygen Concentrations

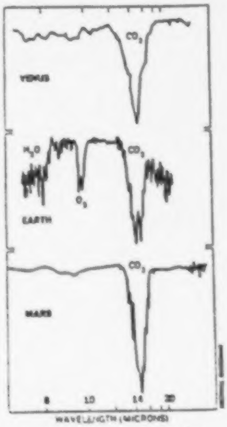
At O_2 levels below 1 PAL, the temperature profile decreases in magnitude as expected based on the results shown in Figure 1 for the ozone mixing ratios. The surface temperature decreases by 4 K as the oxygen level decreases from 1 PAL to 10^{-5} PAL. The temperature profile continues to decrease with a decrease in the O_2 level until 10^{-5} PAL of oxygen is reached. At this point the changes in the temperature with decreasing O_2 level are negligible. It is hoped that future studies can determine more accurate temperature calculations for the stratospheric region. The possible error in temperature values for the stratospheric region of the atmosphere should not affect the ozone column depth data since column depth is not sensitive to these minor details.

Following these calculations, a separate radiative transfer code (HITRAN) will be used by a future study to calculate the absorption spectrum of ozone for the various atmospheric oxygen concentrations. Of great interest in these absorption spectra is the depth of the 9.6 μm band for the various atmospheric oxygen concentrations. Venus, Earth and Mars all have atmospheres rich in CO_2, but only Earth possesses abundant H_2O and O_3. The presence of O_3 on a particular planet implies that O_2 is also present on that planet. If O_2 is indeed present on a particular planet this implies that photosynthesis is occurring. It is the biological process of photosynthesis that implies the presence of life on a particular planet. As shown in Figure 4, the infrared signature of life, the 9.6 μm ozone band, can only be seen on Earth. Thus the infrared signature that this space-based interferometer will be looking for in its hunt for worlds similar to our own in other solar systems is the 9.6 μm band.



SOURCE: R. Hanel, Goddard Space Flight Center

Figure 4 The Infrared Signature of Life (Angel and Woolf, 1996)

Based on the absorption spectrum for differing atmospheric oxygen concentrations calculated by the HITRAN code, the depth of the 9.6 μm ozone band for various concentrations of oxygen can be determined. These depth values for the 9.6 μm ozone band can eventually be compared with the absorption spectrum returned by the space-based interferometer. If the returned values are similar to those calculated for present atmospheric oxygen concentration of the Earth, it can be inferred that the extra-solar terrestrial planet in question also contains a level of atmospheric oxygen concentration that is similar to the Earth's. More generally, the O_2 level on the extrasolar planet can be inferred by comparing the observed 9.6 μm absorption band with those predicted at different O_2 levels. Detection of the 9.6 μm absorption band on another planet would be very significant since it would raise the possibility of life existing on that extrasolar terrestrial planet because O_2 originates on a planet through the photosynthesis process, a process of living things.

CONCLUSIONS

The ozone mixing profiles and the temperature profiles were shown to decrease with decreasing O_2 concentrations. These values upon inclusion into a separate radiative transfer code will be able to calculate the absorption spectrum of ozone for various atmospheric oxygen concentrations. This is a critical step in the utilization of the space-based interferometer to detect planets similar to ours that display the 9.6 μm band ozone signature that is only found on the Earth.

The improvement of the information rendered by Magnetic Resonance Imaging (MRI) depends critically on the knowledge of the behavior of radio frequency (RF) electromagnetic fields inside the human body. The behavior inside gelatins that mimic the electrical properties of human tissues was studied. The gelatins were fabricated and their electrical properties were measured as a function of saline concentration and frequency. Then, phantoms were built using patches of those gelatins and the field profiles and temperature changes were measured as they were exposed to electromagnetic radiation. Results from the electrical characterization of the samples, a map of the electrical field and temperature changes are shown.

INTRODUCTION

MRI is a technique used to obtain pictures of the inside of the human body. It is particularly useful in imaging soft tissue. In fact, what is imaged, is not the tissue itself but the nuclei of a given chemical species contained in that tissue. This chemical species could be hydrogen, sodium, potassium (G.N. Holland, P.A. Bottomley and W.S. Hinshaw , 1977), phosphorus (P.C. Lauterbur, 1973), fluorine (P. Mansfield, P.K. Granell, 1973), and others. Due to the high content of water inside the human body, hydrogen is the most common element imaged.

Under the application of a strong external static uniform magnetic field (~1T=10,000 Gauss) along the z-axis, the spins of these nuclei will be aligned along z. The spin orientation can be manipulated (rotated) and, in particular be taken away from the z-axis by means of radio-frequency (RF) electromagnetic fields in the x-y plane. The maximum efficiency of this rotation happens when the frequency of the RF field and the magnitude of the static field are related through $w = g B$, where g is the gyromagnetic ratio of the proton (26000 1/Gauss). This is called the resonance condition. Off resonance rotation can also exist but it is far less efficient.

A slice of human body to be imaged is obtained in the following way: a "linear gradient" static magnetic field is superimposed on top of the uniform field. This produces a static magnetic field which is different in different slices of the body, thus the resonance condition is met only at one slice (actually a small slab). The rest of the image appears black. A gradient also exists inside the slice, in order to encode the various parts of the region (A. Abragamn, 1961, E.R. Andrew, 1969). The angle by which those spins are rotated depends on the strength of the RF magnetic field and on the time it remains turned on. Knowledge of these angles is crucial in obtaining the images (the closer the angle to 90°, the stronger the radiated signal from that point). The fact is, that the mere presence of the object being imaged (the human body in our case) modifies the RF field. In other words, the RF field depends not only on the field-generating antenna that we have but also on the electromagnetic properties of the material into which these fields are penetrating. In order to obtain sharper images in MRI, one needs to improve the signal-to-noise ratio. This can be done by increasing the static magnetic field, and consistently the MR frequency (A. Abragamn, 1961 and E.R. Andrew, 1969).

Many different systems have been studied and published in the literature (P.A. Bottomley, E.R. Andrew, 1978, F.R. Zypman, R.W. Brown, E.M. Haacke, 1987, F.R. Zypman, E.M. Haacke, R.W. Brown, J.L. Patrick, 1987, F.R. Zypman 1988, A. Jasinski, T. Jakubowski, M. Rydzy, P. Morris, I.C.P. Smith, P. Kozlowski, J.K. Saunders, 1992, C.J. Scheider, N. Engelberts, J.D.P. Van Dijk, 1991, T.K.F. Foo, C.E. Hayes, Y. Kang, 1992).

BEST COPY AVAILABLE

Among them, the most popular ones are spherical, cylindrical and planar models. The first one is well suited for studies of MRI of the head, the second for whole body imaging and the third in flat regions of the body, its strengths being in simplicity and possibility of accounting for multiple-layer systems. Also, many different coil geometries have been considered, from simple loops to more complicated shapes, trying to uniform the RF fields inside the imaged bodies.

A systematic study of radiofrequency (RF) penetration in biomaterials for Magnetic Resonance Imaging (MRI) applications is complicated for various reasons. First one does not have easy mechanical access (like to introduce electric probes) to the inside of the human body without producing damage. Second, the theory cannot be exactly defined given the variety of geometries produced by each particular individual (for example hearts are not all of the same size). Third, the electrical properties of the organs imaged are not always very well known.

In our laboratory a variety of systems that mimic the human electrical properties but that are electrically well characterized, and can be mechanically intervened, are studied. For that purpose saline gelatins are made. They are electrically characterized, that is, their conductivity and permittivity are measured as functions of frequency. Then, phantoms were built with patches of those gelatins. Those phantoms could be spheres embedded in a larger medium or just human-like. The phantom is radiated from coils (see Figure 1) and then we measure field profiles from small loops. Also SAR (specific absorption rate) can be measured using thermocouples.

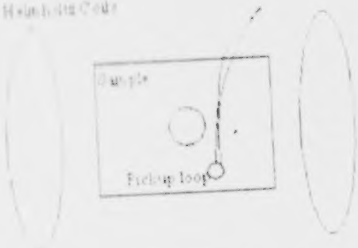

Figure 1. Experimental Model

EXPERIMENTS

Synthetic Biomaterials

Our goal is to fabricate gelatins that mimic the electrical properties of human tissue. Basically we say that a gelatin is a good model for a certain biological tissue if the dielectric constant and the conductivity between the two objects is the same. In order to simulate this properties we vary the saline concentration of the gelatin.

To fabricate the samples we use a solution of H_2O, Agarose 8%, and NaCl. To simulate real tissue the amount of NaCl is varied as 0.8%, 0.9% and 1%.

Conductivity Measurements

To measure the conductivity a sample of the gelatin was cut of 2cm x 1cm x 0.3cm. A constant current source (LakeShore 120) is used to apply a current of 10 µA to the sample. This current is small enough to avoid over heating the sample. Using an electrometer (Keithley 610C) we monitor the change in voltage across the sample as a function of time during a time period of 3000 seconds. This procedure is repeated for samples with 0.8%, 0.9%, and 1% NaCl.

To obtain the conductivity (σ) of the gelatins, the definition of resistance for the sample and Ohm's Law were used

$$\sigma = \frac{Il}{AV} \qquad (1)$$

where I is the applied current, V is the measured voltage, l is the length, and A is the cross sectional area of the sample.

BEST COPY AVAILABLE

Dielectric Constant Measurements

To measure the dielectric constant of the gelatins a sample of 5mm x 7mm x 1.5mm was used. A parallel plate capacitor was fabricated using silver paint to create two metal plates with the sample as the dielectric material. The capacitance of the samples was measured as a function of frequency and time using an impedance bridge (HP4274A). The dielectric constant (k) is obtained using the definition of capacitance for a parallel plate capacitor and the dimensions of the sample:

$$k = \frac{C\,d}{A\,\varepsilon} \qquad (2)$$

where C is the capacitance, d is the distance between the plates, A is the area of each plate, and ε is the permittivity of free space (8.85 x 10^{-12} F/m).

Electromagnetic Field Profiles

MRI could provide unreliable information if not enough care is taken regarding the interaction between the radio frequency fields and the object under study. A well known example of this is the presence of a black spot in pictures showing the brain. The spot does not represent a real hole in the brain but rather an absence of fields there. Our objective is to produce two and three dimensional maps of electric fields inside the tissue like gelatins as a function of frequency.

For the experiment, a tank (20cm x 27cm x 40cm) filled with gelatin (0.9% NaCl) as in Figure 1 was used. Initially, the voltages in points (x, y, z) were measured separated by 1mm through the tank. A three dimensional map of the equipotential lines in the tank were made to verify that the effect of the probe is negligible. Then, the tank was filled again introducing a metallic sphere (radius 2cm) inside, as shown in Figure 1. A RF signal generator is used to apply an electrical field to the system. To measure the electrical field inside the tank we fabricated a 20cm probe. The probe is connected to a digital multimeter to monitor the voltages inside the tank. The voltages were measured in a two dimensional plane across the tank.

Temperature Measurements

MRI has a reputation for been one of the safest diagnostic techniques. However, one of the main concerns regarding safety is related to tissue heating. Federal standards establish the maximum allowed temperature variation under different conditions. These changes in tissue like gelatin as they are exposed to electromagnetic radiation were studied.

To study the changes in temperature as they are exposed to electromagnetic radiation we use the tank in Figure 1 connected to a RF signal generator. To monitor the temperature changes a thermocouple is inserted in to gelatin. The data acquisition process is controlled by a PC computer with the software LabVIEW. The interface between the thermocouple and the computer is provided by a data acquisition card and a signal conditioning card (National Instruments SCXI 1200).

In this study we concentrated in monitoring the temperature increase during the first 30 seconds after the RF signal generator is activated. The measurements are performed as a function of the frequency of the applied field.

RESULTS

Conductivity Measurements

The results of the conductivity measurements for the samples with 0.8%, 0.9%, and 1% NaCl are shown in Figure 2. The results were of the order of 1 S/m and the conductivity increases with an increase in saline concentration. The conductivity for the samples increases during the first 2000s and then it reaches a stable value.

The exception is the sample with 1% NaCl that is very unstable after 2000s. This behavior is probably because the concentration of NaCl is too high.

Dielectric Constant Measurements

First, the dielectric constant was measured as a function of frequency for a sample with 0.9% NaCl. The results obtained are in the desired order of magnitude of 10 and decrease as a

BEST COPY AVAILABLE

function of frequency. In the experiment the frequency range is limited to that provided by the impedance bridge (100 - 100KHz).

Figure 3 shows the results of the dielectric constant measurements as a function of time. The measurements were performed at a frequency of 100kHz during 2000s. The results show that the dielectric constant decreases as a function of time.

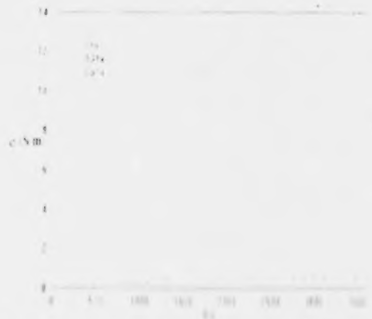

Figure 2: Conductivity of Tissue Like Gelatin.

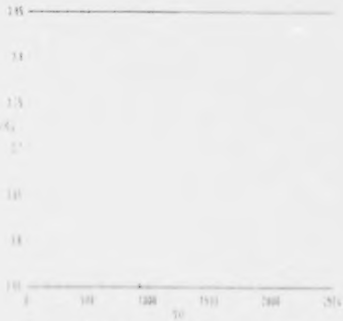

Figure 3: Dielectric Constant of Tissue-Like Gelatin

Electromagnetic Field Profiles

The results of the three dimensional map for the tank filled with 0.9% NaCl gelatin show that the effect of the probe is negligible (i.e. parallel equipotential lines were obtained).

The results of the measurements with the sphere inside the tissue-like gelatin are shown in Figure 4. The shapes of the equipotential lines demonstrate the presence of the sphere at the center.

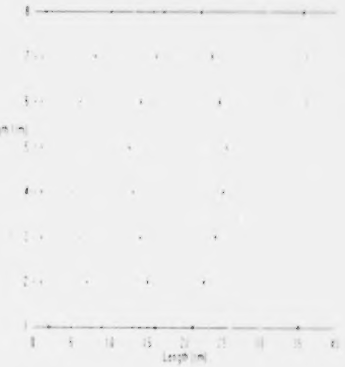

Figure 4: Equipotential Map for Metallic Sphere Inside Tissue Like-Gelatin

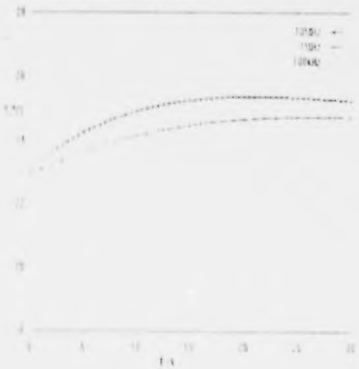

Figure 5: Tissue Like-Gelatin Heating

Temperature Measurements

The results of the temperature measurements as a function of frequency are shown in Figure 5. When the RF electromagnetic field is activated, there is an increase of a few degrees C and then the temperature becomes stable. Also the temperature increases with an increase in the frequency of the applied field. A similar behavior is expected until a resonance frequency is reached. Future experiments are needed to test this statement. The initial increase in temperature with time (ΔT/Δt) is proportional to the Specific Absorption Rate

BEST COPY AVAILABLE

(SAR), the rate of energy deposition in a unit of mass of tissue due to exposure to a time-varying field.

$$\frac{\Delta T}{\Delta t} = \frac{(SAR)}{C} \qquad (3)$$

where C is the specific heat capacity.

CONCLUSIONS

By varying the saline concentration, samples of gelatins with electrical properties (conductivity and dielectric constant) similar to those of human tissue were fabricated. Mapping the electrical field inside the tissue-like gelatins allow us to obtain information about the object under study. Finally, monitoring the temperature changes in the samples we can obtain information about the SAR in gelatins.

Traditional inverse geology techniques have most often been applied to identifying key events in the Grenvillian metamorphic, magmatic and tectonic history of the Adirondack Mountains in New York. This study is the first study to employ the forward technique of modeling the thermal effects of intrusions as a method for providing insight into this history of the Adirondacks. As the correct model for the Grenvillian history of the Adirondacks is currently under debate, mainly as to the depth of anorthosite emplacement, this study provides important constraints to the depth of emplacement and ultimately to which model of the Grenvillian history of the Adirondack Mountains is more viable. To develop these constraints, a two-dimensional finite difference algorithm was written to solve the equation for conduction of heat in solids. The effects generated by single and multiple intrusions at shallow (<10 km) and deep (>25 km) were modeled to determine the plausibility of the Marcy massif as a composite pluton. In addition, two different initial thermal structures were used: a typical continental thermal structure and a hotter continental thermal structure, to simulate a doubly-thickened crust. Results largely suggest that the Marcy massif was intruded deeply in multiple events, in a thickened crust. Significant additions can be made to the model to more accurately simulate the process of magma emplacement and cooling and it is suggested that numerical modeling be used in further study of the Adirondacks.

BACKGROUND

In recent years Valley and O' Neil (1982), Valley (1985), Bohlen et al. (1985), and McLelland and Chiarenzelli (1990) have employed the polymetamorphic model to explain the Grenvillian metamorphic, magmatic and tectonic history of the Adirondacks. Central to the polymetamorphic model is the emplacement at shallow depth (<10 km) of large volumes of anorthosite. However, evidence presented by Florence, et al. (1995) and Alcock and Muller (1997) suggest another model for the Grenvillian history of the Adirondacks, that of crustal thickening followed by anorthosite emplacement at depths greater than 20 km. Field and petrographic evidence suggest high-temperature, and moderate to high pressure metamorphism were a result of anorthosite intrusion at depth.

All previous work in the Adirondacks has used traditional geology techniques to determine the geologic history. Field, petrographic, and petrologic studies employ inverse methods to determine the past history. However, this study provides the first forward technique as applied to the study of the Adirondacks. This study uses thermal modeling of intrusions to determine constraints for the depth of emplacement of the Marcy Anorthosite massif. By estimating the effects at different depths, the two models of deep and shallow emplacement can be tested to determine which is more viable.

MODELING HEAT TRANSFER IN SOLIDS

Using basic principles of heat conduction in solids (see for example, Peacock (1989) or Furlong, et al. (1991), both discuss the basis of thermal modeling), a two-dimensional finite difference computer model was developed. Variables used in the following equations are defined in Table 1. The first equation used is Fourier's law:

$$q = -k\nabla T. \qquad (1)$$

The equation for heat conduction in solids is given by:

$$-\int_a q\,da + \int_v A\,dv = \int_v \rho C \frac{\delta T}{\delta t}\,dv. \qquad (2)$$

t	Time	s
T	Temperature	°C
∇T	Temperature gradient	°C km^{-1}
x	Horizontal component	m
z	Vertical component	m

Suitably combining equations 1 and 2 yields:

$$\nabla^2 T + \frac{A}{K} = \frac{1}{\kappa}\frac{\delta T}{\delta t}. \tag{3}$$

Using a two-dimensional finite difference approximation of equation 3 yields:

$$T_{i,j}^{n+1} = T_{i,j}^{n} + \kappa\Delta t\left[\left(\frac{T_{i+1,j}^{n} - 2T_{i,j}^{n} + T_{i-1,j}^{n}}{(\Delta x)^2}\right) + \left(\frac{T_{i,j+1}^{n} - 2T_{i,j}^{n} + T_{i,j-1}^{n}}{(\Delta z)^2}\right)\right] + \frac{A}{K}. \tag{4}$$

Here the subscripts i,j refer to spatial grid points in a finite difference grid and the superscript n refers to the time grid points. Therefore, the temperature of a grid point after one time step of Δt, $T_{i,j}^{n+1}$, equals the temperature of that grid point at the initial time $T_{i,j}^{n}$, plus a weighted combination of the temperature of all the neighboring grid points. For calculations, a grid of 100 x 50 was used, with fixed boundary conditions of zero at the surface and the background geothermal gradient temperatures along the sides and at the bottom. Explicit finite difference schemes are only stable when relatively small time steps are used; in this case, time steps must be less than 7,922 years to ensure mathematical stability. The model used a time step of 5,000 years to ensure this stability. The background geothermal gradient was established by using an exponential decay of radioactive elements with depth in the crust, given by:

$$T = T_s + \frac{q_m z}{k} + \frac{AL}{k}(1 - e^{-z/L}). \tag{5}$$

MODEL RESULTS

Initial tests of the model involved intrusions of a single magma body at t=0 and allowing for simple conduction to cool the magma over time. However, regardless of deep or shallow intrusion or the volume of the intrusion, very high temperatures could not be reached at any distance from the intrusion, except along the contact. This required a reassessment of the scenarios for magma intrusion and it was eventually decided that a multiple injection model was better suited for testing. This corroborates well with evidence of multiple stages of deformation of the Marcy anorthosite massif, suggesting the massif was intruded in multiple stages.

Using values of T_s=0, K=2.25, q_m=0.03, A=2×10^{-6}, and L=10 km, to establish the geotherm and of 1mm^2/s for thermal diffusivity, which are typical of continental geotherms today, the model was run with multiple intrusions, each intrusion displacing the previous. This is geologically unreasonable but provided an end member case to test. Intrusions every million years at both deep and shallow depths produced higher temperature gradients than a single intrusion but temperatures where not very high for any great distance from the intrusion.

Further evaluation of the model led to the realization of the absence of an important heat source that had previously been neglected, latent heat. Using a method, described by Jaeger (1964), which adds the equivalent temperature of latent heat to the initial intrusion temperature, thus conserving energy, the latent heat was accounted for. It is important to note however, that this method overestimates the temperature along the contact and thus, for practical purposes, these values were generally ignored and gradients were calculated beginning 1-2 km from the contact. At this distance, the problem of temperature overestimation has disappeared and the temperatures are valid.

Using typical values of latent heat of 100 cal/g and a heat capacity of 0.25cal/gK, the model was run with multiple intrusions. The addition of the latent heat term was the equivalent of adding 400 degrees C to the intrusion temperature and this proved to create a leveling of the

BEST COPY AVAILABLE

gradient, on the orders of 100 deg. C/km for shallow intrusions and 50-75 deg. C/km for deep intrusions. Further refinement of the model allowed for user input of the timing and placement of intrusions, so that more accurate geological scenarios could be tested.

The final test of the model yielded the results shown in Figures 1 and 2. For this model, multiple intrusions, spaced at half a million years, were intruded beside each other. In addition, values of q_m=0.04, k=2.0, A=3x10^{-6}, and L=15 km were used to simulate two possible scenarios, a hotter crust in the Proterozoic or a regime that had been crustally thickened. The results of this model run created gradients around 100 deg. C/km for shallow intrusions and around 50 deg. C/km for deep intrusions. However, what is important for this scenario is the extent to which high temperatures are reached, especially around deep intrusions. Temperatures in excess of 800 deg. C occur almost 5 km above the intrusion and the gradient is near horizontal below the intrusion.

A WORD OF CAUTION TO THE READER

Though the results of this study point to deep intrusions, in the proper thermal regime, of creating high-temperature metamorphism at distance greater than 5 km from the contact, there are several assumptions in the model. First, the pluton geometry was approximated as a rectangle. Secondly, the intrusion is assumed to be emplaced instantaneously. In addition, although the latent heat term is correct in that it satisfies conservation of energy, it overestimates the temperature along the contact and it does not release the latent heat in a nonlinear fashion, as Neksavil (1988) suggested is the case. However, the overestimation of temperature along the contact is not important for implications of this study, which focuses on more regional effects of intrusions, rather than contact metamorphism. One final note is that several heat sources were left out, because they are complex to implement. The heat sinks are advective heat transfer, lost through hydrothermal fluids, often set in motion by intrusions, and metamorphic reactions, which are endothermic and consume heat. Magma convection was neglected; this provides fresh hot magma from the base of the magma chamber to the top and thus acts as a heat source.

CONCLUSIONS

Generally, all attempts to generate shallow temperature gradients around shallow intrusions failed. However, given a particular thermal regime, such as a hotter Proterozoic crust or a crust that has been doubly thickened, intrusions at depths > 20 km can produce high temperature metamorphism at distances on the orders of 5 km from the contact. In light of the Grenvillian models for the history of the Adirondacks, this study would suggest that deep emplacement of the anorthosite s favored but that drawing this conclusion indefinitely is premature, given the cautions outlined above. However, thermal modeling provides a powerful tool for testing different geological scenarios and the potential of this model, with the additions of the terms neglected above and using a more accurate geometry, is great.

INTRODUCTION

The photodissociation of nitrogen dioxide (NO_2) plays an important role in the photochemical production of ozone in the global troposphere as well as being a large contributer to the production of acid rain.[1] High levels of this nitrogen oxide in the atmosphere will affect human health both directly and indirectly. The direct effects include the impact on the human respiratory system. The indirect effects of nitrogen oxides are due to their direct effect on animal and plant life and how these effects impact human life. The production of acid rain and the increased levels of ozone in the atmosphere result in the depletion of aquatic life in rivers and streams, as well as leaching out nutrients in soil. This affects humans by reducing wildlife, as well as subjecting these animals to contamination from additional pollutants that result directly from the original NO_x contamination. Human beings may also be impacted by the fact that many of these contaminated animals (i.e., fish) are consumed by humans. Monitoring the different sources of NO_2 and its dispersion into the atmosphere will be helpful to develop strategies to control the concentration of tropospheric ozone through a control of NO_2 concentration.

The most significant anthropogenic source of nitrogen oxides is the combustion process. The two largest components of this are automobile pollution, and pollution from power generation plants. In the upper troposphere, nitrogen dioxide levels are high in the area where air traffic is most prevalent.

There are a number of techniques presently in use for monitoring environmental NO_x pollutants.[2] The most popular is chemiluminescence. This technique is rather expensive and can monitor only one pollutant at a time. An alternative method which is often used is to employ passive diffusion tubes which measure the integrated amount of a pollutant absorbed over a period of about a week. This technique also requires chemical analysis. Another technique, based on lasers, is differential optical absorption spectroscopy (DOAS). In this method one uses a high pressure xenon lamp source and measures the molecular absorption spectrum as a function of wavelength. Using this technique, one can obtain a sensitivity of about 1 ppb for a variety of pollutants including VOC molecules. The main drawback of this method is that it is quite expensive and requires elaborate optical alignment.[3]

The new diode laser-based techniques are attractive. They only need small samples, can monitor samples in real-time, and can be automated easily using computers.

SAMPLE PREPARATION

A quartz tube gas cell of approximately 1 meter in length was used for the absorption measurements. The glass cell was fitted with optical windows and evacuated. The evacuation system consisted of a mechanical pump, diffusion pump and a liquid nitrogen trap. The cell was connected to a high purity nitrogen dioxide cylinder using appropriate stop cocks. The cell was evacuated a couple of times and was pumped for several days so that surface absorbed molecules were removed. The cell was then filled with nitrogen dioxide gas at a pressure of 800 mbar and was used for the measurements.

LASER ABSORPTION MEASUREMENTS [3,4]

In order to choose an optimal optical absorption line, we studied the absorption spectrum of nitrogen dioxide over an extended laser wavelength range. This procedure would enable us to select an appropriate transition matching with the diode laser output. A high resolution Ti-sapphire laser, which was pumped by a 6 W argon ion laser, was used for the laser absorption measurements of NO_2 as a function of laser wavelength in the region 640 - 840nm. The Ti-sapphire laser gives a continuously tunable output in the region 600 - 1000 nm, and the linewidths are less than 1 GHz. The experimental arrangement consists of a multiple pass optical cell. The following observations were taken with 4 passes. More passes were impossible because the beam spread was large and needed secondary focusing. A schematic of the experimental arrangement is shown in Figure 1. The transmitted laser intensity was measured with the help of a diode detector and lock-in detection to improve the signal to noise ratio. The cw laser output was chopped with a mechanical chopper at a frequency of 500 Hz to enable lock-in detection. Table 1 shows some of the prominent peaks observed in this research as comnared with data available in the literature.

FREQUENCY MODULATED SPECTROSCOPY USING DIODE LASERS LOCKED TO AN EXTERNAL CAVITY [6,7]

Semiconductor lasers offer a number of attractive features for monitoring pollutant gases in the atmosphere. Diode lasers are efficient, compact in size and provide tunable output with excellent intensity stability. The power requirements of diode lasers are quite low and they can be conveniently operated by batteries. Diode lasers can be easily electronically modulated even at high frequencies. Diode laser tuning can be accomplished in a number of ways: (1) temperature tuning (2) injection current tuning and (3) external cavity tuning. Though lead salt diodes are traditionally used for monitoring environmental pollutants, they are not convenient for field monitoring because they have to be operated at liquid nitrogen temperatures

FREQUENCY-MODULATION SPECTROSCOPY FOR TRACE POLLUTANT DETECTION

During this decade, a variety of frequency-modulation methods have been reported for high-sensitivity detection of pollutant gases in the atmosphere. Frequency-modulation detection techniques enhance the sensitivity for trace gas detection. These techniques provides real-time quantitative measurement of a wide variety of species with high sensitivity and fast response. Though these methods are known as wavelength-modulation spectroscopy (WMS), frequency modulation spectroscopy (FMS) and two-tone frequency-modulation spectroscopy (TTFMS), they are basically similar in methodology except for the range of modulation frequencies and their number. The choice among these three techniques is driven by the laser tuning characteristics, the absorption linewidth, and the detection bandwidth. The detection can be at single, double or higher order harmonics; the choice again depends on the particular experimental conditions.

By modulating the diode laser's frequency at rates above the diode's shot noise level, the effective signal to noise ratio is improved. In addition to this, by detecting at a second harmonic of the modulation frequency, the signal to noise ratio is further improved.

DIODE LASER LOCKED TO AN EXTERNAL CAVITY OR A REFERENCE NO_x CELL

Fine wavelength tuning and stability can be accomplished by locking the laser to an external cavity. In this arrangement the diode laser emits light radiation at the frequency selected by the external cavity, thus minimizing the problems associated with instabilities, mode hops, and tuning gaps of a free running diode laser. The high

BEST COPY AVAILABLE

Q of the external cavity results in a narrower linewidth of the laser output. The external cavity arrangement also provides continuous tuning over a wider range than a free-running diode laser. The desired frequency is chosen by rotating the gold mirror, which has good reflectivity in the near infrared region such that the appropriate portion of the first order maximum from the diffraction grating is reflected back to the grating and then back into the laser. This rotation also changes the cavity length such that a standing wave is maintained for the selected wavelength. The rotation of the mirror is controlled by means of a Piezo drive. A virtual instrument (software program) developed using the LabView programming environment enables one to vary and control the amplitude, frequency, and waveform of the ramp signal across the Piezo drive.

Employing WMS, we first studied the detection of rubidium in a rubidium optical cell. The rubidium optical cell was prepared by introducing rubidium in an evacuated optical cell and then sealing it off. The experimental setup used is shown in Figure 3.

CONCLUSION

Laser absorption measurements of NO_2 are reported covering the 640- 840 nm region. A number of new absorption lines are reported in comparison to existing literature. A Ti-sapphire laser and multi-pass NO_2 cell are used for the measurements.

Peter A. Barnes

ABSTRACT

The diffusion of dopants into semiconductors requires inserting the sample to be diffused and the diffusion source into a furnace. The sample and the source heat in a finite time from room temperature to the final diffusion temperature. During the time the sample temperature is increasing, the diffusion coefficient increases rapidly. However, there is negligible diffusion depth during the early stages of diffusion. The calculation and data presented show that (a) the sample's temperature rise is exponential and (b) diffusion is insignificant until the sample temperature is within about 5% of the final temperature. This temperature is reached approximately 3 time constants after insertion into the furnace.

INTRODUCTION

High packing density in integrated circuit fabrication requires precise shallow placement of diffused dopants. Shallow diffusions demand short diffusion times. As the time of diffusion shortens, the time required to raise the temperature of the ampoule becomes a significant portion of the total time required for diffusion. Observations indicate that during the temperature rise of the ampoule, there is negligible diffusion for some period of time. This "incubation" period lasts until the ampoule has reached a temperature close to the final temperature.

In this paper a model for the rise in temperature of the diffusion ampoule and its effects on the calculation of diffusion depth will be presented. The rise in temperature of the ampoule can be modeled using Newton's law of heating and cooling. Once the temperature schedule of the ampoule is known, the diffusion depth can be accurately determined.

THE HEATING SCHEDULE OF THE DIFFUSION AMPOULE

In order to accurately predict diffusion depth for short times, the rise in temperature of the sample must be taken into account. The sample does not rise to the final diffusion temperature instantaneously, and can be modeled with Newton's equation for heating and cooling:

$$\frac{dT}{dt} = -k(T_2 - T_1)\,, \tag{1}$$

where k is a constant to be determined and T is the temperature. Beginning at $t = 0$, $T(0) = T_i$, the initial temperature rises to a final temperature $T(\infty) = T_f$, and equation (1) yields:

$$T(t) = T_i + (T_f - T_i)\left[1 - \exp\left(\frac{-t}{\tau}\right)\right]. \tag{2}$$

where τ is the time constant of the furnace. This equation was examined for two cases. [1] The heating schedule of the diffusion ampoule was established for a sample inserted at an initial temperature T_i into a furnace at final temperature T_f (curve 1 in Figure 1). [2] For this case, the furnace temperature was initially increased above the final diffusion temperature (curve 2 in Figure 1). The sample was then inserted, and the furnace temperature was decreased to the final diffusion temperature. This was done in order to shorten the rise time of the ampoule, and caused a slight overshoot in sample temperature (curve 3 in Figure 1).

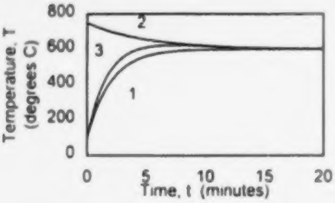

Figure 1: The ampoule rise(1), the furnace cooling(2), and the ampoule overshoot(3).

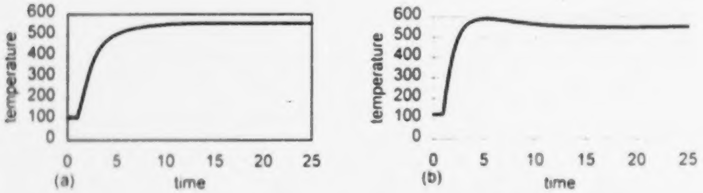

Figure 2: The heating schedule of the diffusion ampoule inserted in: a furnace at constant temperature T_f = 550°C (a), and a furnace at initial temperature T = 700°C decreased the final temperature T_f = 550°C upon insertion of the ampoule (b).

In Figure 2, the temperature rise data is shown for the diffusion ampoule. The data is separated into the two cases described above.

DIFFUSION DEPTH

Two solutions of the diffusion equation will be described below. The first solution assumes that the diffusion coefficient is independent of temperature, and the second solution assumes that the diffusion coefficient varies with temperature.

$$\frac{\partial^2 C}{\partial x^2} = \frac{1}{D}\left(\frac{\partial C}{\partial t}\right) = \frac{\partial C}{\partial (D t)} \quad \text{for constant D} \tag{3}$$

If the surface concentration is constant, the solution is given by:

$$C(x,t) = C_{surf}\, erfc\left(\frac{x}{\sqrt{4Dt}}\right). \tag{4}$$

The diffusion depth is usually defined as the point:

$$x = x_j = \sqrt{4Dt}. \tag{5}$$

The diffusion coefficient D is assumed to have the form:

$$D = D_0 \exp\left(\frac{-E_a}{kT}\right). \tag{6}$$

Taking these equations the junction depth can solved for each of the two cases. In both cases, it is assumed that D_0 is approximately constant, because its temperature dependence is much less than that of the exponential. For the first case, the diffusion coefficient will be treated as independent of temperature, by taking the temperature to be constant with respect to time. Although the diffusion mechanism in GaAs is not strictly Fickean, experimental data is found to fit equations of the same form as (4) and (5), viz.:

$$x_j = 2\sqrt{D_0 t}\exp\left(\frac{-E_A}{2kT}\right) = A\sqrt{t}\exp\left(\frac{-B}{T}\right). \qquad (7)$$

where $A = 2\sqrt{D_0}$, and $B = E_A/2k$. With this experimental fit in mind, consider the effects of the finite rise in temperature of the diffusion ampoule.

This solution implies a linear relationship between x_j and $\sqrt{t}$. For equation (7), diffusion begins as soon as the ampoule is inserted into the furnace, and the diffusion is ideal. However, the ampoule does not rise to temperature instantaneously. It has a finite temperature rise time, which will be approximated with a linear ramp, as shown in Figure 3. Beginning with equation (3), incorporate the temperature dependence of the diffusion coefficient. The temperature dependence is a function of time, so defining a temperature dependent function:

$$T(t) = \int_0 D(t)dt, \qquad (8)$$

equation (3) becomes:

$$\frac{\partial^2 C}{\partial x^2} = \frac{\partial C}{\partial T(t)}, \qquad (9)$$

which has the same form as equation (3), so equation (4) is now:

$$C(x,t) = C_{surf}\,erfc\left(\frac{x}{2\sqrt{\int_0 D(t)dt}}\right). \qquad (10)$$

The linear temperature ramp has the form:

$$T(t) = T_0 + rt, \qquad (11)$$

where r is the rate of rise, and T_0 is the initial temperature. Since we will show that diffusion is delayed until $T = T_f$ we will set $T_0 = 0$ in order to simplify the equations:

$$x_j^2 = 4D_0\int_0^{T_f/r}\exp\left(\frac{-E_A}{krt'}\right)dt'. \qquad (12)$$

Making the substitution:

$$u = \frac{E_A}{krt'} \qquad du = \frac{-E_A kr}{(krt')^2}dt' \qquad (13)$$

yields

$$x_j^2 = \frac{4D_0E_A}{kr}\int_{E_A/kT_f}^{\infty}\frac{e^{-u}}{u^2}du. \qquad (14)$$

This equation can be solved two different ways. The first method follows Killoran (1962), and solves the equation by integrating by parts. The integral can also be evaluated numerically. To continue with the first method:

$$x_j^2 = \left(\frac{4D_0E_A}{kr}\right)K(y). \tag{15}$$

Define

$$K(y) = \int_y^\infty \frac{e^{-u}}{u^2}\,du. \tag{16}$$

Integrate by parts to get a power series in y:

$$K(y) = \frac{e^{-y}}{y^2}\left(1 - \frac{2!}{y} + \frac{3!}{y^2} - \frac{4!}{y^3} + \ldots\right) \approx \frac{e^{-y}}{y^2} \quad \text{for large values of } y. \tag{17}$$

which gives the junction depth as:

$$x_j^2 = \frac{4D_0E_A}{kr}\left\{\frac{\exp\left(-E_A/kT_f\right)}{\left(E_A/kT_f\right)^2}\right\} = \frac{4DkT_f^2}{E_Ar}. \tag{18}$$

Substituting the diffusion coefficient, D, into the equation for junction depth yields,

$$\Delta t \cong \frac{kT_f^2}{E_Ar} = \frac{T_f^2}{2Br}, \tag{19}$$

keeping only the first term. The time interval Δt is the additional time of diffusion needed to calculate the correct diffusion depth, as shown in Fig. 3(b), and B is defined in equation (7).

EXPERIMENTAL DATA

In order to test this model the ampoule is assumed to follow a linear temperature ramp, and compared to two cases in which the ampoule came to temperature instantaneously. This translated into two instantaneous diffusions bounding a case in which the diffusion process was delayed by the heating of the ampoule. Diffusion begins with a high initial rate, and then levels off to the rate for the ideal case. By extrapolating backwards to find the intercept, we find the effective additional time, Δt, of diffusion. The effective time represents the time at which diffusion would have begun if treated as an ideal case.

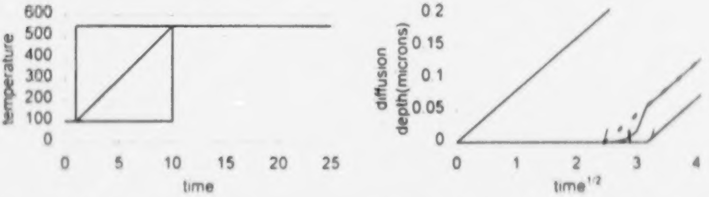

Figure 3: Two ideal temperature rises bounding a linear rise (left); two ideal diffusions bounding a varying one. 't' is the additional diffusion time (Δt) (right).

Experiments were performed diffusing zinc into GaAs using a Zn_3As_2 source. Zn_3As_2 decomposes into Zn and As. The Zn is the diffusion source, and the As provides an overpressure which prevents the decomposition of GaAs. The time of diffusion was measured beginning with the insertion of the diffusion ampoule into the furnace. Diffusions from 10 min to 1000 min. were considered. After staining the samples, the diffusion depths were measured on an SEM. The experimental data is plotted in Figure 4, and the lines are fitted using equation (7) with:

$$\begin{aligned} A &= 2.1 \bullet 10^{4} \mu / \sqrt{\min} \\ B &= 12825K \end{aligned} \tag{20}$$

For the numerical solution to the exponential integral, we used MathCad to the calculation. The linear portion of the plot was projected back across the axis to calculate the effective diffusion time. This solution shows the increase in diffusion depth upon insertion of the ampoule and is plotted in Figure 3(b).

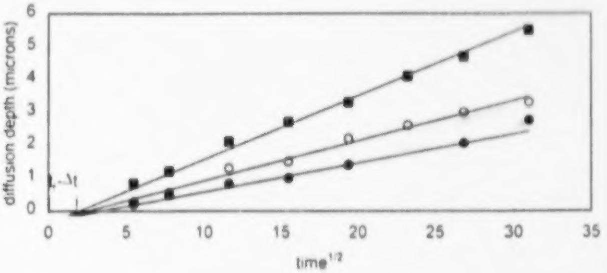

Figure 4: A plot of diffusion depth in microns vs. the square root of time in minutes: the solid lines show the fitted model, the points show the experimental data.

In conclusion, for shallow diffusions in which the diffusion time is not large compared to the heating of the diffusion ampoule, the diffusion depth can be modeled in two stages. Newton's law of heating and cooling describes the behavior of the diffusion ampoule upon insertion into the furnace. Then taking into account the temperature rise of the ampoule, the diffusion can be modeled by solving the diffusion equation with a temperature dependent diffusion coefficient. The result of this model is that the diffusion process does not begin immediately. There is an incubation period until the ampoule has been heated for a time within Δt of the final temperature. The incubation period (t_i-Δt), (see Figure 4) can be estimated and then used to determine the diffusion depth.

The Hyperpolarizabilities of Phthalocyanines

Tiffiani R. Williams

Department of Chemistry
Spelman College
350 Spelman Lane
Atlanta, GA 30314-4399

Faculty Advisor:

Beatriz H. Cardelino

The hyperpolarizabilities of molecules is studied in a search for optimum compounds to be used in non-linear optical devices. The phthalocyanine molecule has been investigated. The molecule was studied theoretically using the MOPAC and HYPER programs. The hyperpolarizabilities were calculated using semiempirical Hamiltonians (AM1 and PM3). The hyperpolarizabilities of the entire molecule and of the different segments of the molecule (e.g., inner ring structure, isoindoles structure) were studied to find the greatest contributing segment. The hyperpolarizabilities of similar molecules (e.g., porphyrins) were also compared with the molecule and its different segments. Finally, the effect that a metal (Zn) has on the hyperpolarizabilities was also investigated.

BACKGROUND

Non-linear optical materials have a variety of potential uses in the future due to their ability to allow the control of light by light [1]. Materials with large second- and third- order polarizabilities are the key for future photonics applications. They have the potential for applications in optical computers as switches or high density optical recordings [1]. In the field of non-linear optics, the need for organic molecules with high non-linear hyperolarizabilities is great. The hyperpolarizability (second-order polarizability) of a molecule is the measurement of the efficiency with which the molecule can generate second harmonics [2-4]. The hyperpolarizabilities are greatest in highly polarizable molecules. It has been shown in previous research that conjugated and aromatic organic molecules demonstrate the largest non-linear optical properties [5]. The phthalocyanine molecule (see figure 1) was studied and calculations resulted in a hyperpolarizability of $1.73 * 10^{-49}\ \mathrm{Cm^3V^{-2}}$ [5]. This is unusually high due to the fact that the molecule is primarily symmetrical which would make it nonpolar. However, there is one point of asymmetry in the molecule which occurs in the d ring of the structure (see figure 1e) which could be the segment that causes its high hyperpolarizability. In this research, a comparative study was performed on the phthalocyanine molecule in order to determine the greatest contributing unit to the high molecular non-linearity. Thus, the molecule was broken into different segments (see figure 1) and H atoms were added to make the molecules neutral and non-radical. The hyperpolarizabilities of the different pieces were found and compared, when possible, with other molecules of similar structure.

CALCULATIONS

The approach followed in this work is to obtain an initial geometry of the molecule from semiempirical calculations using the AM1 and PM3 Hamiltonians, then optimize this structure to minimize energy. This lowest energy optimized geometry is then subjected to a variety of static fields using semiempirical techniques. This method provides information on the polarization versus static field strength, which can then be analyzed to find the second order polarizability or hyperpolarizability β using the finite field formulation, according to equation 1:

$$P(F) = \mu + \alpha F + \beta F^2 + \gamma F^3 \qquad [1]$$

where μ is the permanent dipole moment, α is the linear polarizability, and γ is the third order polarizability. The calculations were done using the semiemperical MOPAC program [6] and the HYPER [7,8] program, in which the calculations of molecular hyperpolarizabilities have been implemented.

The molecules studied were derivatives of the phthalocyanine molecule (see figure 1:a-j) which were selected by removing different segments of the molecule and then adding hydrogen molecules to make the molecules neutral and non radical. As shown in figure 1, the half of the molecules contain a zinc atom within the porphyrin cage. The effect of this zinc atom on the hyperpolarizability was calculated. The phthalocyanine cage was also studied with and without the zinc atom. Due to the similarity of the phthalocyanine cage and the porphyrin ring, the hyperpolarizability of the porphyrin was also calculated and compared with the phthalocyanine cage.

RESULTS

In these calculations, the determination of the hyperpolarizability of the phthalocyanine was much lower than expected, and had a large uncertainty (see table 2). This large uncertainty is due to an unsatisfactory optimization of the geometry. The geometry of the molecule is modified by changing the atom coordinates until optimum energy can be reached, but the optimization is very dependent on the initial geometry. The molecule 1j, however, expressed an extremely high hyperpolarizability in comparison with the other phthalocyanine molecules. This molecule is symmetrical except for the position where ring d would be placed. Thus when the isoindoles structure of the molecule is removed, the polarity of the molecule is greatly increased.

As known from previous results, there is an element in the porphyrin ring that produces a high hyperpolarizability when zinc is placed within the cage. Zinc also causes an increase in hyperpolarizability for the phthalocyanine ring, although not as dramatic as for the porphyrin. In figure 2 we see that when compared, the porphyrin ring with a zinc atom has a hyperpolarizability approximately 1000 times higher than the porphyrin ring without the zinc atom, the phthalocyanine cage with the zinc atom and the phthalocyanine cage without the zinc atom.

CONCLUSION

It was found that the phthalocyanine ring with two segments on the top and bottom of the ring (see figure 1j) produced the greatest hyperpolarizability with the smallest uncertainty for all of the molecules. This fact leads us to believe that this could possibly be the greatest contributing unit. Future research will include a study on the hyperpolarizabilities associated with addition of substituents onto the phthalocyanine ring in the top and bottom (t&b, see table 1) positions. Research is already in progress to synthesize this unsymmetrical molecule.

Simulated Super Resolved Imaging of Compact Radio Sources

Many celestial radio sources have structure on the order of light years, corresponding to an angular resolution below the standard beam size of 1 milliarcsecond. Because the structure is below the conventional resolution limits, it is important to test the standard mapping and modeling programs for systematic errors when such data is used. From studying the programs DIFMAP and MODELFIT, we have found that there do exist some systematic errors and have tested several solutions to reduce these errors.

INTRODUCTION

For many hundreds of years, people used only optical telescopes in observing astronomical phenomena due to the fact that they are naturally equipped with devices to observe electromagnetic waves from the visible part of the spectrum. Then in 1932, Karl Jansky identified the first celestial radio source at which point radio astronomy was born. Radio astronomy opened up a whole new window through which scientists could study celestial bodies. Not only could scientists learn more about sources that had been studied previously using only visible wavelengths, but some sources with structures too faint to be seen optically could now be studied in greater detail. Due to the many improvements over the years, today radio telescopes can achieve better resolution than most optical telescopes, and so radio astronomy has become very important in gaining a better understanding of a wide variety of astronomical objects.

Early problems with radio astronomy dealt with resolution. Since the radio waves studied (from celestial sources) have wavelengths on the order of centimeters, a telescope with a diameter too large to be practical in a single telescope was needed to achieve any kind of resolution comparable to that achieved by optical astronomy. This can be seen from the formula for angular resolution,

$$\theta \sim \lambda/D \qquad (1)$$

(with θ in radians) where λ is the wavelength of radiation and D is the diameter of the telescope. The technique developed to study compact radio sources is known as VLBI or Very Long Baseline Interferometry. The radio telescopes in an array spread out over a large distance are linked together electronically. The rotation of the earth causes the waves arriving at a pair of telescopes to be successively in phase and out of phase; so, the telescope array "sees" the sky as a series of bands of constructive and destructive interference. A computer can then take the amplitude and phase patterns collected from many pairs of telescopes and convert them into an image of the celestial radio source. Higher resolution can be achieved using VLBI because the distance between the farthest pair of telescopes becomes the diameter of the radio telescope.

PROJECT OUTLINE

When studying real radio sources, each telescope in the given array records the radio emissions from the source. Then a special purpose computer known as the correlator combines these signals using principles of interferometry. The correlator output is written to a tape which can be read into a computer where the data can be processed and used to create an image of the source. From measurements made on the image, numerical values can be obtained for relative location, size, and intensity of each component. For our purposes, we required data for which we already knew the relative locations, sizes and intensities. Using the FAKE program (from the Caltech VLBI Software package), it was possible to simulate the observation of a celestial radio source by having the computer create an artificial data file based on a model. This data file is then used in other programs as if it were a true source.

The main array of telescopes used for this project was the VLBA or Very Long Baseline Array, which consists of ten stations ranging across the US from St. Croix in the Virgin Islands to Mauna Kea in Hawaii and north to Brewster in Washington. Each telescope has a diameter of 25 meters, a 70% efficiency, and a system temperature (system power) of 60 K. The wavelength of radiation we used, a mid-range value, was λ=3.6 cm (equivalent to a frequency of 8.4 GHz) which gives, using the VLBA diameter, a resolution of $\theta \sim 1$ mas (1 milliarcsecond = 1 thousandth of an arc second).

When studying radio sources, the conventional beam size is approximately 1 mas. Many remote radio sources (including quasars and the nuclei of galaxies) turn out to be extremely compact, which means they are only a few light years in diameter. This corresponds to an angular resolution below the conventional beam size. Therefore, it is important to test the accuracy of imaging and modeling programs on sources below this limit (This corresponds to going beyond the familiar Rayleigh or Sparrow criterion). In addition to viewing structure at compact sizes, it is also important to be able to detect subtle variations in structure corresponding to the relative movement of the components. With these ideas in mind, we set out to investigate the potential and limitations of super-resolved imaging of compact radio sources using the Caltech programs DIFMAP and MODELFIT (Pearson 1991).

Most of the models we worked with were simple two component sources. The important parameters were flux, component separation, position angle, component size, and declination. The declination refers to the position of the source in the sky. Because the VLBA has a larger east/west than north/south spread, the shape of the beam (and therefore the resolving ability) will vary with declination. Here we used models at a high declination of 60°, corresponding to a circular beam, and a low declination of 15°, corresponding to an elliptical beam. Also, because the resolution was different depending on direction, we varied the position angles in increments of 45° from 0° to 135° (Position angle gives the position of a component relative to the central component. The angle is measured counterclockwise with 0° being directly north of the central component). The total model flux was usually about 100 mJy (where 1 Jansky=10^{-26} W/m^2/Hz). To determine whether the flux of each component affected other parameters we used low flux ratios such as 2:1 and 6:1, a mid-range ratio of 8:1, and high flux ratios of 10:1 and 15:1, with the first component having the highest flux. Component separations ranged from above the beam size at 2.0 to below the beam size at 0.2 mas. To study both compact and extended sources, we used component sizes or diameters of 0.1 and 0.3 mas.

DIFMAP RESULTS

Using the DIFMAP program (Shepard, Pearson, & Taylor 1994), the computer performs a Fourier transform on the amplitude and phase interference data received from the source to create an image of the source which is known as the "dirty map." The computer initially treats the object as a point source and then iteratively builds up a more complicated, accurate model by imaging the difference data after removing the effects of structure from previous iterations. During each iteration, the response of the array to a point source (called the "dirty beam") must be removed in a technique called "cleaning." In cleaning, a box is drawn around the brightest component of the source and a specified amount of flux is subtracted to reveal less luminous components. The result, after several iterations, is a "clean map" which is the "true" image of the radio source. Between each "clean" step and remapping, the *selfcal* command is used to determine telescope phase and gain corrections by "self calibration", i.e. comparing the observed data with an approximate model of the source structure. When the selfcal values converge or decrease to below 1 sigma the cleaning process is finished. The *mappl cln* command produces a "clean map" of the source using the standard beam for the given telescope array and declination. For our model sources where the component separation was less than the standard beam size (at dec=60° the beam is .993 x .962 mas at 41.1° and at dec=15° the beam is 1.56 x .85 mas at -4.19°), the second component could not be seen on this clean map. To see the two components separately we changed the beam size to be 0.25 mas circular which is roughly 1/4 the standard VLBA beam size at dec=60°. Reducing the beam size, in most cases, enabled us to see each component separately. We could then print a hard copy of the clean map and measure the component separations and position angles to compare with the true model values.

For all flux ratios, we noticed a positive separation discrepancy which increased as the true separation decreased. This discrepancy remained constant as the absolute flux level of the components was increased. At high declination, the discrepancy was independent of position angle; however, at low declination the separation discrepancy appeared to depend on position angle, with PA=0° showing the most severe discrepancy.

There originally seemed to be a trend for a positive discrepancy in position angle at low declination and a negative discrepancy at high declination, but this was not true for all position angles. This trend was definitely apparent for PA=45° at all flux ratios with the discrepancy increasing as the true separation decreased (except for a true separation of 0.2 mas). At PA=90°, tests were done at the low flux ratio which confirmed the results of the PA=45° tests at the low declination, but gave correct position angle values at the high declination. So there may be a trend toward positive PA discrepancies for PA=45° and 90°, i.e. those angles more nearly perpendicular to the major axis of the beam.

Once we had established the position angle and separation discrepancy trends, we tried invoking several different tasks in DIFMAP in an attempt to reduce these discrepancies. First we tried changing the weighting scheme which could be done using the command *uvweight*. The uniform weighting scheme we had been using weighted each data point by the inverse of the number of points in a box of fixed size in the aperture (uv) plane. We tried using natural weighting, instead, which gives equal weight to each visibility. We noticed the same discrepancy trends for separation and position angle as in the uniform weighting tests; however the discrepancies using natural weighting were somewhat higher than those found using uniform weighting (which makes sense since natural weighting gave more weight to the shorter baselines than uniform weighting did). Since we wanted to place more emphasis on the longer baselines (the baselines with the better resolution), we also did a few tests deleting some data from the short baselines by changing the *uvrange*, but this lowered the discrepancy only very slightly.

In another test of the weighting, we used the *selftaper* command to place more weight on the longer baselines than on the shorter baselines. From a uv plot we found that most points were between 0 and 50 mega-wavelengths so we successively decreased the weight of these points by a factor of 10 each time (from 0.1 to 0.0001). The most extreme case was 0.0001 at 100 mega-wavelengths. These tests revealed the smallest separation discrepancies for the case of a 0.4 mas true separation so far. The separation values from each successive test fluctuated from 0.55 to 0.59mas, still a large discrepancy.

In addition to changing the weighting scheme, we also tried to eliminate the position discrepancies by refining the cleaning technique. Mapping is an interactive process where the user selects a region of the image and draws a box around it on the computer screen. Standard technique is to box the brightest region of the image, clean a specified amount of flux, self-calibrate, and then draw a box around each successive bright region that appears. We "re-difmapped" some of the previous models using only one box around the first and second components. Using only one box eliminated the separation discrepancy for the 0.8 mas true separation and significantly decreased the discrepancy for 0.6 and 0.4 mas true separation. We did several tests at RA=0.4 varying the position angle from 0° to 135° at dec=15 for flux ratios of 2:1, 8:1, and 15:1. The separation discrepancy was independent of flux ratio, but did appear to depend on position angle. The separation discrepancy was smallest for PA=90° since for the elliptical beam the east/west direction has the best resolution. The separation discrepancy increased as the position angle moved away from 90°. The worst separation discrepancy was at 0° since the north/south direction has the poorest resolution. The position angle discrepancy was positive at angles below 90° and negative at angles above 90°, and seems to show a mild positive correlation with flux ratio. Combining the one box test with the most severe selftaper resulted in the same values found with one box and no selftaper.

MODELFIT RESULTS

The MODELFIT program fits Gaussian profile components to the interferometric data. The result is a table of numerical values for the intensity, size and location of each component of the source. The tests of the MODELFIT program involved varying flux, separation, position angle, and axis (component size).

For the low flux ratio cases (2:1 and 6:1) the program overestimated the size of the separation by a few hundredths of a milliarcsecond (mas). For the high flux ratios (8:1, 10:1, and 15:1) the program underestimated the separation by a few hundredths of a mas. This trend appears to be independent of the declination, position angle and component size.

We only noted a significant discrepancy in the flux ratio for the low flux ratio cases (2:1 and 6:1). From tests done, this discrepancy is always positive, and appears to depend only on the separation. For large separations (0.8 mas and above), the flux ratio only varied slightly from the original model. For smaller separations, the discrepancy increased with decreasing true separation, increasing to as much as 4:1 in the case of a 2:1 true ratio (for the true 6:1 case, the discrepancy increased to approximately 7:1). At true separations of 0.4 mas and under, the discrepancy in the flux ratio remained constant.

For cases where MODELFIT was run on the models with components of unequal size, a diameter discrepancy was noted. In the low flux ratio (2:1) case only, the small diameter was overestimated and the large diameter underestimated, even going to zero on occasion. This effect increased with decreasing true separation, but leveled off and in some cases even reversing at very small separations (0.4 to 0.2 mas) where the flux ratio had leveled off. This effect was the same at both declinations and at each position angle.

Because of the apparent interdependence of the discrepancies in separation, flux ratio, and component size, we ran several tests holding one of the three parameters (flux, separation, and diameter) constant each time. For a separation from 1.0 to 0.6 mas the program found the right answer (for each variable parameter) regardless of which parameter was held constant. For separations of 0.4 and 0.2 mas, the right answers were found holding the flux ratio constant, but holding another parameter constant led to errors in the two parameters that were varied (i.e. holding separation constant led to incorrect values for flux and diameter and holding diameter constant led to incorrect values for flux and separation). These tests led us to conclude that the flux parameter has the greatest influence over all other parameters.

BLIND TESTS

After finishing the models we performed several blind tests to see if we could use the discrepancy trends found in the DIFMAP and MODELFIT tests to get the correct values for source parameters. Several tests were set up with models that covered the range of model parameters which we had been using in our previous tests. In order to employ the one box scheme, it was necessary for the user to first draw a box around the core. Then when the second component could be seen, the user could start from scratch and draw one box to encompass both components. We also found that it was necessary to input 2 to 3 times the peak flux (shown on the DIFMAP plot) of the extended component as a starting value for MODELFIT in order to get the correct results. After adding extra flux to the second component, the true values of the parameters fit within the error bars.

CONCLUSION

The results presented here details of the super-resolution tests that have been summarized in Barth, Hough, and Davis (1996). These results indicate that the DIFMAP and MODELFIT programs do have some problems when the structure of the source requires super resolution, but as yet, only some of the details of these problems are known. A deep understanding of the systematic effects will only come with a much larger study covering a wide range of sources and telescopes. Although it is too early to advertise a "correction table" for automatically adjusting results from real data, it is not too soon to begin warning observers to beware of errors and search for them in their data.

Funding for this project was provided by NSF grant AST-9422075.

ABSTRACT

We report the first milliarcsecond-resolution, simultaneous-multi-frequency VLBA radio images of the nucleus in the lobe-dominated quasar 3C263. We confirm apparent accelerated superluminal motion in the parsec-scale jet, and identify a flat-spectrum "core" and a steep-spectrum "jet". We discuss physical conditions in the nucleus and implications for unification of active galaxies.

INTRODUCTION

Billions of light-years away, at the very edge of our expanding universe, lie some very fascinating quasi-stellar objects that we refer to as quasars. These distant objects are the subjects of many extensive studies that have sought to pin down their exact characteristics. In seeking to explain these phenomena, observers and theorists alike have devised potential unification models that would bring together different types of active galactic nuclei, of which quasars are an extreme example. In our studies of the radio-loud, lobe-dominated, superluminal quasar 3C263, we have found evidence that supports these models.

Under current models, quasars have certain things in common. They all have a supermassive black hole in their center with an accretion disk circling around it made up of very hot gas and other material; many eject some of this matter in a bipolar fashion from the central "core" in "jets" that fill huge "lobes". Previous studies of these active galactic nuclei have provided us with evidence of relativistic outflows that move at apparently superluminal (faster-than-light) speeds. These jets have been explained using simple relativistic beaming models in the past which have attempted to account for the wide variety of core-dominated and lobe-dominated quasars, as well as radio galaxies. Unfortunately, these models are doubtlessly oversimplified, and more intensive observations are needed to constrain more complicated beaming models.

To probe the innermost recesses of these active galactic nuclei, a technique known as Very Long Baseline Interferometry (VLBI) has been developed. Using a large array of radio telescopes in different parts of the world such as the Very Long Baseline Array (VLBA), the VLBI technique can be used to combine the interference of the various telescopes. This provides multiple baselines that, in effect, simulate both small and large apertures. The resulting "synthesized aperture" allows us to probe sub-milliarcsecond structure with very reliable results.

Our observations of the superluminal, lobe-dominated quasar 3C263, in conjunction with multiple previous observations (see Zensus, et al. 1987 and Hough, et al. 1996), provide stronger evidence for both acceleration and nonradial motion of its jet components. These results have led us to question the standard beaming model used to explain various quasar characteristics. Using six other epochs of both 10.7 GHz and 8.4 GHz data, we report further superluminal motion as well as strong evidence for acceleration. In addition to high-resolution observations, the VLBA now allows us to perform simultaneous, multi-frequency observations. With spectra thus obtained we were able to make further calculations that revealed other physical properties of the quasar 3C263.

These results were presented briefly in Beyer, et al. (1996). Here we provide comprehensive details and discuss their implications for the current standard models.

OBSERVATIONS AND DATA REDUCTION METHODS

The quasar 3C263 was observed on November 15, 1995 for 12 hours at three simultaneous frequencies. The ten VLBA antennae around the United States observed 3C263 at 4.971 GHz, 8.405 GHz, and 15.349 GHz. This wide range of frequencies allows us to analyze spectral information that has not previously been available in the radio wavelength range. In addition, the multiple epoch observations of 3C263 in the past allow us to make detailed investigations of the physics of this lobe-dominated quasar.

To reduce this data, we used two software packages common to the astrophysical community. With the latest version of the NRAO AIPS software on Sun workstations we performed the initial editing and phase calibration of the data. Once these preliminary steps were completed, the data was ported to the CalTech VLBI Software environment where other specific data editing and amplitude calibration took place, with utilization of the DIFMAP program (see Shepherd et. al. 1994) for the actual Fourier imaging.

RESULTS

Structure

The structure of the nucleus of 3C263 at the epoch 1995.87 is best represented by four Gaussian components in the 5 GHz and 8 GHz observations, but only three components in the 15 GHz data. This discrepancy is probably due to the optically thin nature of the fourth and weakest component, making it especially dim at higher frequencies. In each of the attached figures, the core component (C) has been modeled as elliptical, but the three jet components (J0, J1, J2) have all been fitted as circular. There is also another discrepancy between the different frequency observations. When the clean maps are super-resolved and all set to the same beam size, the overlaid maps, which are also attached, show that the components are not at exactly the same locations at the different frequencies. We refer you to Figures 1, 2, and 3. While the separations of the various jet components do stay more or less constant, the core component seems to be shifted to the northwest, especially at 15 GHz, when all the maps are lined up on the J1 and J2 components. This is most probably due to the optically thick nature of the core component. As we increase the frequency of our observations, we are able to probe deeper into the structure of the quasar nucleus, and therefore, we can see more of the core.

J1 Motion

A straightforward, weighted least-squares fit to the data for J1 for the first three epochs starting from 1982.75 yields a proper motion of 0.058 ± 0.007 mas yr^{-1} while a fit to the remaining epochs starting from 1984.94 yields a proper motion of 0.12 ± 0.01 mas yr^{-1} and a fit to the entire range of epochs yields a value of 0.105 ± 0.008 mas yr^{-1}. Due to the inconsistency of the linear fits and the absence of an overall agreement, we decided to perform a number of polynomial fits. Of these, the quadratic fit gave the most reasonable values for J1's proper motion and resulted in a very smooth acceleration that seems to agree with the relative errors. The quadratic fit implies instantaneous proper motion relative to C ranging from 0.066 mas yr^{-1} at epoch 1982.75, to 0.150 mas yr^{-1} at the epoch 1991.17, to 0.197 mas yr^{-1} at epoch 1995.87. Thus, J1 shows significant evidence for apparent acceleration.

J0 and J2 Motion

Since they have also been observed at other epochs, we may also analyze the other two jet components' proper motion. Between the epochs 1989.27 and 1991.15, J2 showed a proper motion of 0.03 ± 0.03 mas yr^{-1}, but between 1991.17 and 1995.87, J2 showed a visible increase in proper motion with a value of 0.16 ± 0.02 mas yr^{-1}. Since the proper motion over the entire range of epochs is 0.14 ± 0.03 mas yr^{-1}, it appears that J2 has accelerated in a similar fashion. Similarly, J0 has showed an increase in proper motion over time. A linear fit to the data between the epochs 1991.17 and 1995.87 gives a proper motion of 0.206 ± 0.07 mas yr^{-1}, but over the entire range, the proper motion only reaches a value of 0.17 ± 0.05 mas yr^{-1}. Although the case is not as strong, we conclude that J0 may also show apparent acceleration.

Position Angle

We have also seen evidence for nonradial motion in the jet components of 3C263. The position angles of the jets seem to change with time, but they appear to be dependent on the component's separation relative to the core. Although they are difficult to distinguish, when the components are less than about half a milliarcsecond from the core, they are at a position angle of roughly 113 degrees. Once past this distance from the core, they seem to all be oriented at a rough angle of 111 degrees.

Due to the wide range of epochs we spent observing 3C263, it has become necessary to determine whether there has been any significant field rotation due to precession. Using a standard program to model various component positions in a quasar location identical to 3C263, we were able to determine that the position angles of the components differed from the originals by only two tenths of a degree. Since this is well below our calculated errors, it has no real effect on our data.

Spectral Analysis

With the VLBA, it is now possible to do multi-frequency observations simultaneously. This provides us with a chance to do a spectral analysis of the quasar assuming that its radio emission is due to the synchrotron process. We can calculate the spectral index between the observed frequencies. If we assume that S goes as ν^{α} (where S is the flux density, ν is frequency, and α is the spectral index), then for the C component we find $\alpha = -0.58 \pm 0.03$ from 5 GHz to 8 GHz, and $\alpha = 0.00 \pm 0.02$ from 8 GHz to 15 GHz, and $\alpha = -0.27 \pm 0.03$ from 5 GHz to 15 GHz. This indicates that in the self-absorbed spectrum of the core, its turnover frequency is most probably somewhere between 8 GHz and 15 GHz above which it becomes optically thin. The other components have spectral indices consistent with an interpretation that they are optically thin.

DISCUSSION

Superluminal Motion

Depending on the cosmology one favors, we get different values for the apparent velocity of these jets. Throughout this discussion we assume a Friedmann cosmology with $H_o = 100h$ km s^{-1} Mpc^{-1} and $q_o = 0.5$ so as to give something of a lower limit for a given component's speed, where H_o is the Hubble constant and q_o is the deceleration parameter. While both J0 and J2 exhibit superluminal speeds, the wealth of data on J1 allows us to calculate much more than its apparent velocity. Using the quadratic fit to J1's proper motion, we found J1's apparent transverse velocity to be $>3c$ in the later epochs. Since it is definitely superluminal, we proceeded then to calculate possible line of sight angles, actual speeds, and Lorentz factors which could lead to this apparent velocity. In addition to these calculations, we also calculated Doppler factors and boosting factors for each of these scenarios. Combining the results of these two important calculations forces us to reexamine the beaming model we have adopted. Under the current model, there is an angle and Lorentz factor associated with an actual velocity which yields an apparent transverse velocity greater than the speed of light. While this is mostly accepted as an explanation for superluminal motion, another important aspect of beaming models is their attempt to explain the rise in flux as the line of sight angle decreases. It is here where we run into a problem. Our calculated values for the Lorentz factors and angles can perhaps be manipulated to show a constant speed with varying angles or a constant angle with acceleration. However, when relativistic beaming is used, the corresponding Doppler factors need to be consistent with observed flux densities. Using a test angle of about 20 degrees, our calculations show an acceptable Lorentz factor increase from roughly 1.8 in 1982.75 to 4.8 in 1995.87, and the Doppler factor stays more or less in the same range moving from 2.6 in 1982.75 to 2.5 in 1995.87. Even when these Doppler factors are applied to boosting factor formulae, their respective differences are of order unity. However, if a constant Lorentz factor is taken around 5, the angle shows a very unacceptable decrease of 50 degrees from 70 degrees in 1982.75 to 20 degrees in 1995.87. The Doppler boosting factor also changes by more than a factor of 100. These drastic changes do not correspond to the observed flux values, and since the minimum value of the Lorentz factor for J1 in 1995.87 is about 4.5, we are unable to use a smaller number in the constant Lorentz factor case. Our only plausible explanation, then, is that the jet remains at a relatively constant angle and has been experiencing a true acceleration. As to the cause of this Lorentz factor change, we might speculate that the jet has been recollimated and, much as in a simple fluid model obeying Bernoulli's Principle, has thus been accelerated.

BEST COPY AVAILABLE

Position Angle

We presented evidence earlier that the position angle of the jet component J2 has changed depending on it distance from the core. This raises the question that there could possibly be some different position angle for each component within the inner half milliarcsecond. Although the evidence is not particularly strong, this change in position angle with distance could indicate something more about the innermost regions of the jet, such as nonradial component ejection or a curved path along which all components move.

Synchrotron Theory

After determining certain observable characteristics of 3C263, we can now proceed to derive physical conditions in the source, assuming that the non-thermal radiation we detect is synchrotron radiation. One of these involves the inverse Compton catastrophe. According to this theory, the brightness temperature of a component may not exceed 10^{12} Kelvin, or else inverse Compton scattering will cause it to dissipate its energy. By our calculations, none of the component temperatures came within that value by more than a factor of 100.

Another major concern is with the distribution of the magnetic field in the quasar. Since the majority of this radiation is synchrotron related, the magnetic field plays an important part in our calculations. Since we had spectral results, we were able to calculate the magnetic field in two ways. Using the self-absorbed spectrum of the core we were able to determine that the turnover frequency lies somewhere between 8 GHz and 15 GHz, so we calculated the magnetic field accordingly. It turned out higher than expected, ranging from 1 G to 75 G, but these are still within the range observed at other quasars. Using the equipartition of energy assumption, we obtained much smaller values which ranged from 0.05 G to 0.3 G. Thus, if the self-absorption calculation is reliable, the equipartition condition is not satisfied, and the magnetic field energy dominates. These applications of synchrotron theory to 3C263 help us to confirm some aspects of our models and learn about physical conditions close to the "central engine".

Unification Models

Current theories hold that both the lobe-dominated and the core-dominated quasars are the same astronomical object simply oriented differently in the sky. According to our observations and calculations, 3C263 holds true to this unified model. We have found 3C263's exhibited superluminal motion to be consistent with that of other lobe-dominated quasars and significantly less than other core-dominated ones, which is predicted by the model. The acceleration of the jet components in 3C263 is mild when compared to those of well studied core-dominated quasars, and its flux variations over time are similarly weaker than its core-dominated counterparts. The bend angles are also less than those commonly observed in core-dominated quasars, and the self-absorbed core with optically thin jet components stays consistent with previous observations. All of these characteristics support the unification models that have been proposed. There are also indications that our observations support some of the "grander" unification models which include radio galaxies. Since we have established that 3C263 is most probably oriented at about 20 degrees to our line of sight, it is possible to say that radio galaxies may be only oriented in the 50 to 90 degree range. These models are still being developed, and, with better observations, we might someday be able to come to a final unification conclusion.

J. D. Perez

ABSTRACT

The earth's magnetosphere is the region around the earth in which the solar wind interacts with the earth's magnetic field. Understanding the large scale dynamics of the magnetosphere is a difficult task. Current satellites are able to make in situ measurements which give us data only on a local scale. We are then forced to extrapolate or even guess at the relationship between various measurements. The IMAGE (Imager for Magnetopause-to-Aurora Global Exploration) satellite, to be launched in February, 2000, is the first attempt at global imaging of the magnetosphere. IMAGE will utilize several different methods for imaging the magnetosphere including energetic neutral atom (ENA), ultraviolet radiation, and radio sounding. My research deals with work to aid in designing the ENA instruments to be used on IMAGE and preparing to analyze the data that will be collected with these instruments. Using computer models of the cusp region of the magnetosphere we are simulating the ENA data that will be collected by the satellite. The satellite will see a two dimensional image which must be changed back to a three dimensional image by means of deconvoluting an integral along the line of sight of the ENA instrument. From this we can attain and analyze a large scale three dimensional picture of the magnetosphere which will give more insight into the behavior of the magnetosphere than was previously possible.

BACKGROUND

The earth's atmosphere is so named because the region is dominated by atoms, as the ionosphere is dominated by ions. So it follows that the region around the earth that is dominated by the earth's magnetic field is known as the magnetosphere. The atmosphere extends above the earth's surface about 100 kilometers. The next level is the ionosphere which extends to about 1000 kilometers. Above the ionosphere lies the magnetosphere. The earth's magnetic field is very similar to the magnetic field created by a simple bar magnet as shown in Figure 1. In fact, the source of the earth's magnetic field produces a field that is almost identical to that of a magnetic dipole including having two poles, what we call the north and south poles. However, this field is severely deformed by the solar wind from the sun.

The solar wind is composed of charged particles that are being blown off the surface of the sun along with the sun's magnetic field which extend into interplanetary space and forms the IMF (Interplanetary Magnetic Field). These charged particles are a plasma, which simply means that they are a group of charged particles which exhibit collective behavior. When these fast moving charged particles hit the earth they warp the earth's magnetic field and leave us with a magnetosphere that is shaped something like figure 2. This region extends above the surface of the earth toward the sun about 10 Earth Radii(R_e), or about 60,000 kilometers, and away from the sun several hundred R_e, well past the moon which lies at about 125 R_e.

There are several regions of the magnetosphere, but the studied here is known as the cusp region. The cusp is a funnel shaped region near the poles of the earth. This funnel shape allows charged particles from the solar wind to be 'funneled' into the aurora region near the surface of the earth. However, these solar wind particles are not the only charged particles in this region. Ions from the ionosphere move up the magnetic field

BEST COPY AVAILABLE

lines, away from the earth, into the magnetosphere. This region, near the earth, where these ions are rising out of the ionosphere is the region of interest in this study.

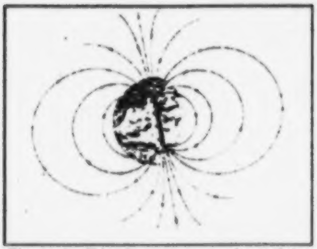

Figure1: Dipole representation of the earth's magnetic field.

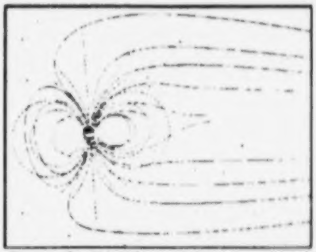

Figure 2: Warping of the magnetosphere by the solar wind (A dipole field is superimposed for comparison).

Current satellites are only capable of making in situ measurements. This means that these satellites can only detect what is touching the satellite. If some object or structure exists a few kilometers away the satellite can not see it. A good example of this problem comes from data that was taken by the satellite Dynamics Explorer 2 in the 1980's. When looking at this data one sees that in a typical pass over the polar regions, the satellite initially sees very few charged particles coming up the magnetic field lines. As the satellite moves through its orbit suddenly the satellite detects a large number of such charged particles. Then, as the satellite continues through its orbit these charged particles disappear. From this type of data it is not possible to be certain whether the satellite flew through some spatial structure in the magnetosphere or if the entire region became active for this period of time.

THE IMAGE MISSION

The IMAGE (Imager for Magnetopause-to-Aurora Global Exploration) mission is the first attempt at global imaging of the magnetosphere. There are four methods by which IMAGE will obtain these global images. The first method involves radio sounding. This method uses the same principle as a submarine's sonar. A radio pulse is sent from the satellite into different regions of the magnetosphere. When these waves hit a region with a high density of charged particles it will bounce back to the satellite allowing us to generate a picture of that region.

The next two methods use ultraviolet imaging. The first of these two images far ultraviolet light. This will provide images of activity in the auroral zones that will allow us to relate the data to previous studies. The second type of ultraviolet imaging uses extreme ultraviolet light. Extreme ultraviolet light is more energetic than far ultraviolet light. This allows the determination of the shape of the plasmasphere, which is a sphere of charged particles that is co-rotating with the earth.

The last type of imaging is energetic neutral atom (ENA) imaging. ENA imaging is the focus of this study. ENA imaging will allow the study of the ion upwelling from the ionosphere.

ENA IMAGING

It is very difficult to obtain an image from a charged particle in the magnetosphere. When a charged particle is in a region where a magnetic field exists, it will not travel in a straight line. This is demonstrated in Figure 3, which shows the behavior of a charged particle which is 'stuck' to a field line. When the particle is moving through a region where there is a magnetic field it will tend to follow the field lines. Since the particle does not travel in a straight line we cannot tell where the particle originated if we detect it with our satellite.

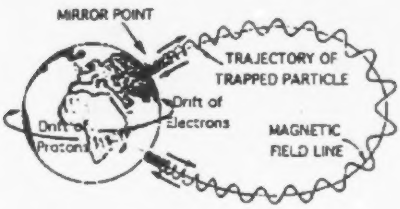

Figure 3: A charged particle moving through a magnetic field.

In order to obtain images from this region we will make use of the existence of the geocorona, a cloud of neutral atoms whose density exponentially decays with distance away from the earth. As the energetic ions rise out of the ionosphere along the magnetic field lines they will interact with these neutral atoms. When one of these ions flies close enough to one of the neutral atoms it will pick up an electron from the neutral atom. This produces an ion that is moving relatively slowly and a neutral particle moving with a high velocity in a straight line that can be detected by our satellite.

Our satellite's instrument is an array of pixels, each of which looks in a straight line from the satellite. Each pixel will detect any neutral particles that are coming towards the satellite along the line of sight of that pixel. By summing all of the particles that are coming toward the satellite along the line of sight for each pixel we can generate an image of the region toward which the satellite is looking. Using a model of the cusp region developed by Dr. Gordon Wilson at The University of Alabama in Huntsville and Marshall Space Flight Center these images can be simulated. A sample simulation is shown in Figure 4. In this image the satellite is located on the night side of the earth, away from the sun, looking down on the north pole from about 3 R_e above the surface.

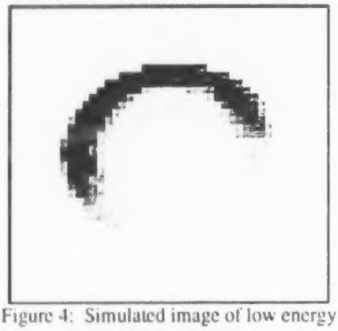

Figure 4: Simulated image of low energy neutral oxygen atoms.

In this image the ion upwelling in the auroral region around the north pole. These images show that sufficient counts can be obtained with our instrument to generate useful images.

CONCLUSION

The IMAGE mission is the first attempt at global imaging of the magnetosphere. It will give insight into the dynamics of this region which will aid in the understanding of the mechanisms that drive this system. IMAGE will go beyond any previous mission by yielding global images on an almost instantaneous time scale. This will allow understanding of how regions of the magnetosphere work as well as how different regions are related. We are working to simulate the images that will be obtained by the ENA instruments in order to help design the instruments as well as develop new techniques for analyzing the data that will be received from the satellite.

The advance of Magnetic Resonance Imaging (MRI) depends strongly on the behavior of radio frequency (RF) fields inside the human body Complete information of RF penetration is hard to obtain experimentally since it requires accessing a solid object in many points This would become a destructive technique and cannot be used for human subjects To circumvent this problem, we have designed a 3D cubic circuit such that between two nodes there is an impedance Z (resistor and capacitor) The impedances are adjusted in such a way as to correspond to the known permittivity and conductivity of the biomaterial that we wish to simulate We will show field profiles at the nodes of the network when suitable voltages are applied at the faces of the cube

INTRODUCTION

MRI is a technique used to obtain pictures of the inside of the human body It is particularly useful in imaging soft tissue In fact, what is imaged is not the tissue itself but the nuclei of a given chemical species contained in that tissue This chemical species could be hydrogen, sodium, potassium[1], phosphorus[2], fluorine[3], and others Due to the high content of water inside the human body, hydrogen is the most common element imaged Under the application of a strong external static uniform magnetic field (~ 1 T= 10,000 Gauss) along the z-axis, the spins of these nuclei will be aligned along z The spin orientation can be manipulated (rotated) and, in particular be taken away from the z-axis by means of radio-frequency (RF) electromagnetic fields in the x-y plane The maximum efficiency of this rotation happens when the frequency of the RF field and the magnitude of the static field are related through $\omega = g B$ where g is the gyromagnetic ratio of the proton (26000 1/Gauss) This is called the resonance condition Off resonance rotation can also exist but it is far less efficient A slice of human body to be imaged is obtained in the following way a "linear gradient" static magnetic field is superimposed on top of the uniform field This produces a static magnetic field which is different in different slices of the body, thus the resonance condition is met only at one slice (actually a small slab) The rest of the image appears black A gradient also exists inside the slice, in order to encode the various parts of the region[4,5] The angle by which those spins are rotated depends on the strength of the RF magnetic field and on the time it remains turned on Knowledge of these angles is crucial in obtaining the images (the closer the angle to 90°, the stronger the radiated signal from that point) The fact is, that the mere presence of the object being imaged (the human body in our case) modifies the RF field In other words, the RF field depends not only on the field-generating antenna that we have but also on the electromagnetic properties of the material into which these fields are penetrating Strictly speaking, then, it is not possible to build a "universal" antenna to create the wanted RF fields, since the fields inside the patient will depend on the patient herself (himself) Even though the RF fields may be spatially uniform under certain conditions, they may be distorted when a given patient is being imaged (this statement is more important as the RF frequency is increased) Many different systems have been studied and published in the literature[6,7,8,9,10,11,12] Among them, the most popular ones are spherical, cylindrical and planar models

BEST COPY AVAILABLE

The first one is well suited for studies of MRI of the head, the second for whole body imaging and the third in flat regions of the body, its strengths being in simplicity and possibility of accounting for multiple-layer systems. Also, many different coil geometries have been considered, from simple loops to more complicated shapes trying to mahe the RF fields inside the imaged bodies uniform.

This work is motivated by the need to understand electromagnetic radiofrequency (RF) field profiles inside biomaterials. RF fields are used in MRI but their exact behavior is difficult to obtain in situ, that is, inside the human body. There are complications, both experimentally and theoretically: experimentally because cutting the body is only done in extreme situations, and theoretically because the Maxwell Equations are cumbersome and the boundary conditions not well defined due to the fact that organ size depends on the patient. So we built a 3D impedance network that mimics the conductivity and resistivity of various organs[13]. In addition, this system has the advantage of being easily accessible.

For wavelengths long compared to the size of the system, Maxwell's equations may be approximated by the simpler electric circuit theory[14]. Quasi-static field theory also applies. An important feature of the field behavior in this range is that the electric and magnetic fields are only weakly coupled. In our study we developed a computer simulation of our model using the circuit simulation program Spice3f4 (electric circuit analysis and simulation program). We will present some results of the simulation.

BIOMEMBRANE MODEL

The objective of our model (see Figure 1) is to represent a body organ (electrically characterized by a conductivity σ_1 and permitivittty ε_1) surrounded by body tissue with different electrical properties, (σ_2, ε_2) an electrical circuit. The tissue elements are represented by an impedances (Z), specifically by the parallel combination of a resistor (R) and a capacitor (C). The values of the impedances are adjusted so that they correspond to the values of σ and ε for human tissues.

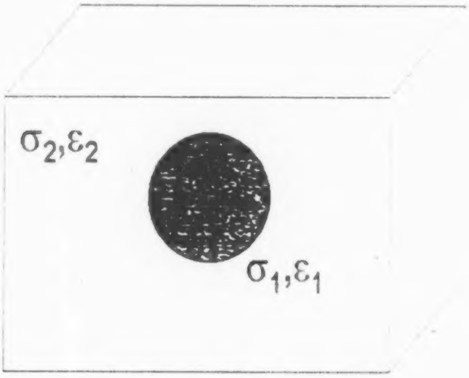

Figure 1. Model of human body organ electrically characterized by σ_1, ε_1 surrounded by body tissue characterized by σ_2, ε_2

Using the basic definitions of resistance and capacitance we can obtain the values of R and C. The different body parts are then represented by three dimensional networks of impedances, as shown in Figure 2.

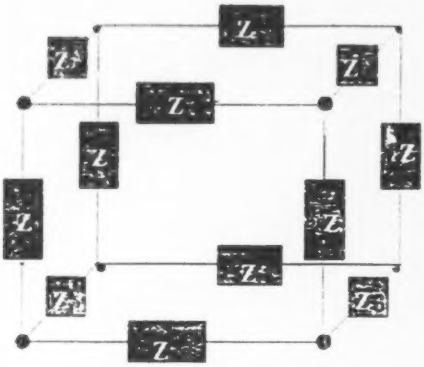

Figure 2 Element of 3D Impedance Network

For our simulation we used values corresponding to muscle and fat The values of Z have been calculated previously as 49 7 - j23 8Ω for muscle and as 510 - j544Ω for fat at a frequency of 1 92 MHZ [15]

To obtain the values of the resistance and capacitance we used the definition for the impedance of an RC parallel circuit

$$Z = \frac{R - jR\omega C}{1 + \omega^2 C^2} . \qquad (1)$$

where ω = 2pf and f is the frequency of the source

The power source used was a sinusoidal ac source and the simulations were performed at frequencies of 64 MHZ, 128 MHZ and 192 MHZ The power was applied between two faces of the cube that were parallel to each other The simulations were performed using the circuit analysis program Spice3f4 in a PC Computer

RESULTS

Using equation 1, we obtained the values of the resistances and capacitances as R=61 kΩ C= 39 nF for muscle and R= 1 09 kΩ and C=0 96 pF for fat For the first simulations we built a 6x6x8 network of impedances representing only one type of tissue (muscle or fat) at a time

We recorded the voltages at the nodes of the network and plotted the equipotential surfaces across it The equipotential lines obtained were parallel to the faces of the cube where the voltage source was applied

Then we repeated the simulation but using a 2x2x2 cube made of a different tissue in the center of the cube A 2D plot of the equipotential lines for a cube of muscle tissue surrounded by fat performed at 192 MHZ are shown in Figure 3 The map shows the presence and shape of the muscle tissue cube No significant changes were found when performing the simulation at 64 MHZ and 128 MHZ

Our results are limited because of the reduced number of nodes With a higher number of nodes we will be able to model organs with different shapes

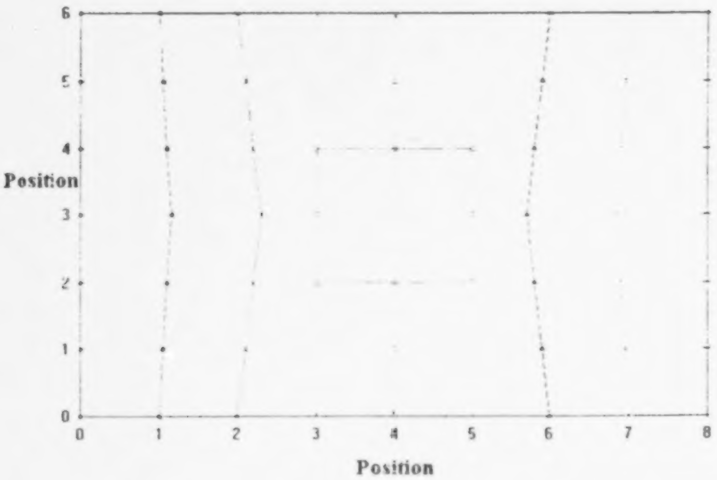

Figure 3 Electric Field Profile for Muscle Tissue Inside Fat Tissue at a Frequency of 192 MHZ

CONCLUSIONS AND FUTURE DIRECTION OF THE PROJECT

We modeled a section of the human body using a 3D cubic circuit where the values of the impedances are adjusted to those corresponding to the impedances of human tissues The interaction with an electromagnetic field was simulated using the program Spice3f4 Our results show that mapping the field profiles at the nodes of the network we obtain information about the object (organ) of study

We plan to extend our model to include a higher number of nodes to represent more tissues and organs with different shapes

A Two-year Climatology of Radiation Budget and Cloud Properties for the ARM SGP Site

Stephen G. Strum

Department of Meteorology
The Pennsylvania State University
503 Walker Building
University Park, PA 16802

Faculty Advisor:

Dr. Thomas P. Ackerman

The Atmospheric Radiation Measurement (ARM) Southern Great Plains (SGP) data set has been analyzed for the period from April, 1994, through April, 1996, to obtain a two-year climatology of surface radiation and cloud properties. Monthly means of both observed and clear-sky solar radiation for the two-year period were calculated, as well as the difference between the two values: the observed cloud forcing. A climatology of cloud base using a combination of micropulse-lidar and ceiliometer data was then created. Using this climatology, the relationship between cloud liquid water path (LWP) as measured with a microwave radiometer and cloud forcing was examined. A significant relationship exists, although a large amount of scatter is present in the data.

INTRODUCTION

Amid a sea of wheat crops in north-central Oklahoma rises a collection of tall antennas and instrument towers. This is the site of the Southern Great Plains (SGP) Cloud and Radiation Test Bed (CART). As part of the Atmospheric Radiation Measurement Program (ARM) of the Department of Energy, the ARM SGP site collects data on numerous atmospheric properties including downwelling and upwelling radiation, cloud base altitude, liquid water path (the amount of liquid water in a column through a cloud), and a host of other local conditions. The program's goals are to improve the understanding of atmospheric processes that affect atmospheric radiation and the description of the same processes in climate models (Stokes and Schwartz, 1994).

Clouds have a tremendous impact on the Earth's radiation budget. Many scientists believe that an increase in cloud cover will be a response of the climate system to increasing greenhouse gases. An increase in certain cloud types could potentially offset some warming that may take place while other cloud types will actually serve to increase warming. As a result, understanding this cloud-radiation interaction becomes important.

One of many projects involved with the ARM program, this research focused on the creation of a two-year cloud and radiation climatology. The period analyzed extended from April, 1994 through April, 1996. Such a climatology allows for various cloud-radiation relationships to be analyzed and parameterizations of the reduction of radiation from cloud properties to be created. These parameterizations can then be implemented in climate models to represent atmospheric processes.

A RADIATION CLIMATOLOGY

An empirical curve fitting technique was developed by Long (1996). This technique involves finding periods of clear sky each day, then fitting a cosine curve to those values. With as few as 110 minutes of clear sky each day, accurate functions describing clear-sky radiation can be generated which have the form

$$\text{Clear Sky Radiation} = a\,(\cos Z)^b \qquad (1)$$

where a and b are coefficients determined by the fitting technique and Z is the solar zenith angle. Coefficients can be interpolated to days that have fewer than 110 minutes of clear sky. Interestingly, the technique determines whether clear sky is present without examining data from cloud measuring instruments.

Liquid water efficiently scatters and absorbs radiation. The sharp reduction in visible light on cloudy days testifies to that fact. Fortunately, the radiation instruments located at the SGP site measure both direct and diffuse radiation. Even on cloudy days, some amount of radiation passes through the cloud cover without being scattered or absorbed; this is direct radiation. Similarly, some of the radiation reflected by clouds is directed towards the ground; this is diffuse radiation. When no clouds are present, the amount of diffuse radiation is minimal. So, by simply examining the magnitude of the diffuse radiation, the presence of cloud cover can effectively be determined. With the implementation of the Long technique over the entire two-year period, the desired radiation climatology became a reality.

Merely examining the raw radiation data, in the form of one minute averages, would not reveal much useful information, so averages needed to be found. By summing the radiation values, then dividing by 1440, the number of minutes in one day, daily averages of radiation were created. This method allowed for day-to-day variations to be examined. For comparisons of seasonal variations, monthly means were created. The monthly means of cloud forcing needed to be normalized in some way as the available solar energy varies by season. The best way to do this is to represent the mean cloud forcing as a fraction of the clear-sky radiation value. Figure 1 shows the mean fractional cloud forcing for each month during the two-year period. Average values of fractional cloud forcing are greatest in spring and winter. The average fractional cloud forcing for spring (March, April, and May) is 0.293 compared to an average fractional cloud forcing of 0.301 in winter (December, January, and February).

The frequency of cloud forcing values was calculated for each season. Figure 2 presents these values. Summer tends to favor low values of cloud forcing, as might be expected, while winter tends to experience the greatest percentage of high fractional cloud forcing events; the frequency of fractional cloud forcing values between 0.6 and 0.85 is twice as high in winter as in summer. A distinct bimodial distribution is also present in winter with the first peak occurring near a fractional cloud forcing value of zero and the other near 0.75. The low sun angle in the winter probably accounts for this distribution. At lower sun angles, a greater amount of shortwave radiation will be reflected by clouds than at a high sun angle, so a given cloud type will produce a greater fractional forcing in winter than in summer. Low stratus cloud events, which often produce large cloud forcing values, also occur more frequently in winter than in summer.

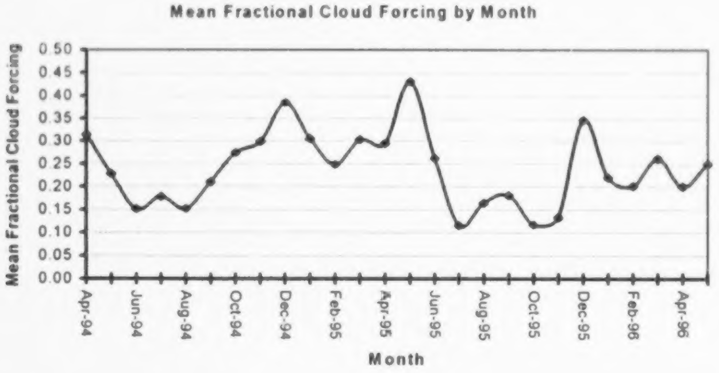

Figure 1. Plot of mean fractional cloud forcing by month for the April 1994 to May 1996 period. Fractional cloud forcing being the cloud forcing value divided by the clear-sky value.

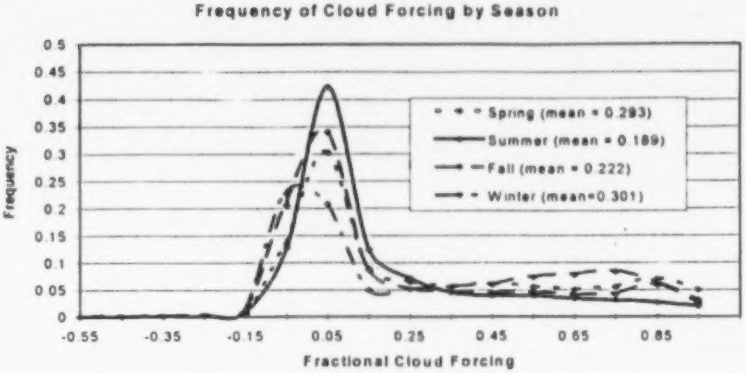

Figure 2. Frequency of cloud forcing by season. The number of occurrences of fractional cloud forcing were tabulated for bins of width 0.10, then normalized by season. Each value on the x-axis denotes a bin center.

A CLOUD CLIMATOLOGY FOR THE SGP SITE

Radiation data by itself can produce useful information relating to cloud forcing, but the type and structure of cloud present for any given cloud forcing event can not be determined. This resulted in the need to create a cloud climatology for the same period as the radiation climatology -- April, 1994 to April, 1996. Then comparisons between clouds and associated radiative forcing could be made.

One cloud characteristic desired was cloud base height. Instruments such as the micropulse-lidar and the ceiliometer measure cloud base quite accurately. The primary drawback is that the instruments have a very small field of view. The conditions present overhead may not be representative of what is occurring in the majority of the sky. Satellite data gives a better spatial representation of cloud cover, but cloud base can not be determined and the exact conditions over the observation site are often difficult to assess.

The primary cloud type of interest in the study were low stratus. The data obtained from the lidar and ceiliometer were used to determine periods with low cloud bases, in this case, less than 2000 meters. Cloud tops could not be determined, so while many stratus cloud cases were probably found, many cases could have been thunderstorm events, or multi-layered cloud deck events.

CLOUD LIQUID WATER PATH

For a given cloud base, almost any cloud forcing can occur because cloud geometry and optical depth vary widely. Cloud characteristics other than cloud base are needed to obtain a better relationship to cloud forcing. One such characteristic is cloud liquid water path (LWP). This is the integrated amount of liquid water in a vertical column through a cloud. Presumably, a cloud with a higher liquid water path will be denser and thicker than one with a low liquid water path. So, high liquid water paths would be expected to correspond to high values of cloud forcing. For the entire two year period examined, 15 minute averages were taken of cloud forcing and liquid water path during periods of continuous cloud cover. Periods with 45 minutes of continuous cloud base measurements as determined from micro-pulse lidar and ceiliometer data were considered to be continuous cloud events. Figure 3 shows the resulting distribution when these two values are plotted against each other. While a good deal of scatter is present, a definite logarithmic relationship exists. Much of the scatter can be attributed to the presence of mixed phased clouds. Ice water will contribute to cloud forcing, yet will not be represented by liquid water measurements. Nonetheless, high fractional cloud forcing values coinciding with high liquid water path values as expected. For very small values of liquid water path though, a very large range of cloud forcing exists. Part of this large range of forcing values may be attributed to errors in cloud coverage measurements. Cloud cover often is not contiguous across the sky, and variations in density and thickness can be present. A cumulonimbus cloud, for example, can reduce the amount of radiation reaching the instruments even though the cloud may not be in the field of view of the instruments.

Figure 4 presents the same data in the form of averages and standard deviations. The logarithmic relationship between cloud forcing and liquid water path is much more apparent. As shown by the standard deviation lines on the plot, the range of fractional cloud forcing values is much less for liquid water paths greater than 0.01 cm than for values less than 0.01 cm.

Above a liquid water path of 0.01 cm, fractional cloud forcing can be estimated quite accurately from liquid water path. Once liquid water path values exceed 0.04 cm, little additional gain in cloud forcing is observed. Changes in solar zenith angle can contribute more to the cloud forcing than an increase in liquid water content of the cloud.

The solar zenith angle, the angle with respect to vertical at which the sun is located in the sky, will influence cloud forcing. More shortwave radiation will be reflected by a given cloud when the sun is low in the sky than when it is directly overhead. This can also contribute to the wide variation in cloud forcing for very low liquid water path values. For the majority of the day though, cloud forcing will not vary significantly as a result of solar zenith angle.

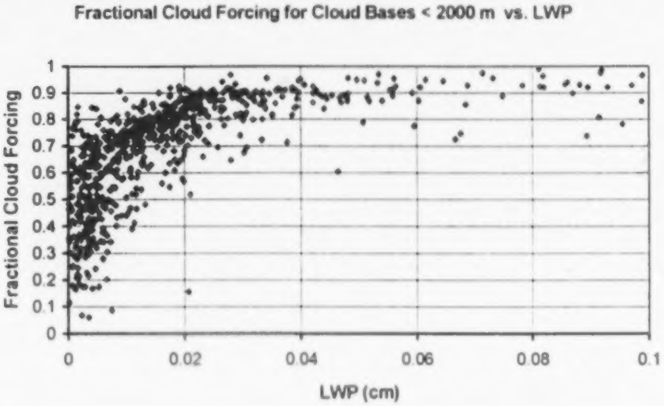

Figure 3. Plot of fractional cloud forcing against liquid water path (LWP). Only cases in which the cloud base, determined from ceiliometer data, was less than 2000 meters were accepted.

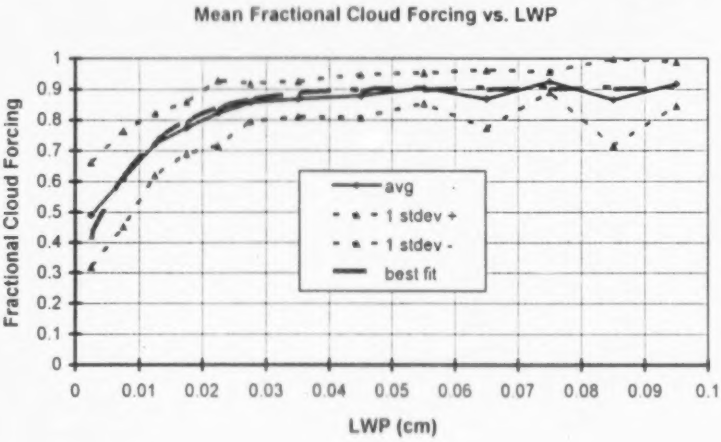

Figure 4. Plot of mean fractional cloud forcing against LWP for cloud bases less than 2000 meters. The dashed curve represents the best fit to the data and has the form: $FCF = 0.9 [1 - e^{(-100 (LWP) - 0.35)}]$ where FCF is the fractional cloud forcing and LWP is the liquid water path in centimeters.

CONCLUSIONS

From the comparison of monthly and seasonal cloud forcing, a definite trend for increased values of cloud forcing during the winter and spring can be observed. Values of fractional cloud forcing greater than 0.35 most frequently occur in the winter and spring seasons and December and May have the greatest mean values of fractional cloud forcing.

The comparison of liquid water path to cloud forcing revealed a significant relationship, however only when liquid water path values exceed 0.01 cm. When examining low-based clouds, liquid water path does provide a reasonable estimation of cloud forcing. The relationship is less useful for mid and high level clouds. Ice reflects and absorbs radiation differently than liquid water and ice crystals are more likely to be present in mid and high level clouds.

In the near future, a cloud radar will be installed at the SGP site. This radar will allow for both cloud base and cloud top to be detected. By comparing the cloud base and top to an atmospheric temperature sounding, the phase of the cloud can be deduced. The result will be more accurate parameterizations of cloud forcing since mixed phase cloud events can be eliminated.

Some evidence has shown that cloud properties can change as climate changes (Lindzen, 1990). If models are to accurately depict cloud-radiation interactions, and resulting surface temperature changes, then the relationships between various cloud properties and cloud forcing need to be understood.

ACKNOWLEDGMENTS

Dr. Thomas P. Ackerman is greatly appreciated for all of his guidance throughout the study. Thanks is also extended to Drs. Gerald Mace, Eugene Clothiaux, and Charles N. Long for all of their helpful conversations and providing needed insight.

This computational investigation explores the effects that halogenated phenyl groups and halogenated methyl groups have on the nonlinear optical properties of the highly conjugated and two-dimensional molecule, porphyrin. Theoretical results are compared with experimental values. Second and third-order polarizabilities are calculated for a series of halogenated porphyrins, tetramethylporphyrins and tetraphenylporphyrins. These computations utilize a modified finite field formalism which include calculations of polarization values versus static electric fields. All calculations are performed on optimized molecular geometry based on semiempirical quantum chemical results using the AM1 Hamiltonian.

INTRODUCTION

Porphyrins are an important class of cyclic conjugated tetrapyrrole molecules which are essential constituents of a number of biological systems. The porphyrin nucleus can combine with metal ions, such as magnesium (e.g., in chlorophyll) and iron (e.g., in hemoglobin). Water-soluble porphyrins have functioned favorably in a variety of novel chemical and medicinal procedures and, most recently as photochemical sensitizers and magnetic imaging contrast agents. Because of their electronic properties, polymers with porphyrin derivatives are promising compounds for possible application as nonlinear optical materials.

As light travels through a material, a variety of nonlinear effects may occur, such as second or third order harmonic generation. The interaction of light with matter can cause the original optical beam to have its frequency, phase, polarization or path changed significantly. These materials provide the means to tailor the nature of light to make suitable applications in optical signal processing, laser technology, optical computing and telecommunications.[1-2] In order to control light, materials scientists must design and synthesize an ideal medium in which a combination of photons can take place and the generated beam can have an appropriate magnitude and response time. These materials are called nonlinear optical (NLO) materials.

In recent years much attention has been given to organic compounds, in view of their unusual large nonlinear response. This characteristic feature is attributed to the large polarization of the delocalized electron cloud. Because of its conjugation and abundance in nature, porphyrin is an ideal candidate.

An understanding of the relation between molecular structure and polarizabilities is emerging which may lead to the discovery of materials with yet improved nonlinear optical characteristics. The polarizability of a molecule can be approximated with the following equation:

$$P = \mu + \alpha F + \beta F^2 + \gamma F^3 \ldots \qquad (1)$$

where μ is the dipole moment, α is the linear polarizability, β is the second order polarizability, and γ is the third order polarizability. Both β and γ are nonlinear polarizabilities.

The efficiency of a molecule to generate second and third harmonics is related to the magnitude of β and γ, respectively. A common procedure for measuring these properties is the DC-induced second harmonics generator (EFISH). The measurement depends on the projection of the β vector on the dipole moment of the molecule. Consequently, the larger the angle ($\mu\beta$) between these vectors, the smaller the measurement. Theoretical computations can be used to estimate the dipole moment, linear polarizability, second and third order polarizability. These computations have the potential to assist greatly in facilitating the design of new NLO molecules.

Method

This computational investigation explored the effect that halogenated methyl groups and halogenated phenyl groups have on the nonlinear optical properties of porphyrin, and focused on the second and third order polarizabilities of these porphyrin compounds, as well as their potential use in polymer matrices. For comparison purposes both halogenated and nonhalogenated compounds were analyzed.

Theoretical calculations have been performed as follows: [3-4]

1. Optimized structures were calculated using the AM1 [5] Hamiltonian implemented within the MOPAC [6] program.
2. Data on polarization versus static electric fields were obtained by including values of fields into the AM1 Hamiltonian.
3. The data was analyzed using the HYPER program within the finite-field approach.
4. Values of dipole moment, linear polarizability, second and third order polarizability were obtained with their associated uncertainties.

Results

Please refer to figure 1 for the designation of the molecules studied. The results are summarized in table 1. The headings of this table are as follows: μ corresponds to the permanent dipole moment, in Debye units; α is the linear polarizability, in $Å^3$; Ave β and +/- are the magnitude of the second order polarizability vector with its uncertainty, in 10^{-51} C m^3 V^{-2}; angle μβ corresponds to the angle (in degrees) between μ and β; γ and +/- are the value of the scalar third order polarizability and its uncertainty, in 10^{-61} C m^4 V^{-3}.

The results are depicted in figures 2 and 3. The vertical columns in figure 2 display the values of β for the molecules studies, and the squares indicate the values of the angles between μ and β. Figure 3 shows the values of γ and the corresponding uncertainties.

The values of β and γ for non-halogenated porphyrin are 23.6 x $10^{-51}Cm^3V^{-2}$ and 20 x $10^{-61}Cm^4V^3$ respectively. When halogens were placed in positions 2, 3, 5, 6, 8, 9, 11, 12 (on the pyrrole) the γ value was increased by only 10% and the β value was reduced by 54% . However when the halogens were placed on the pyrroll bridge (positions 1, 4, 7, 10), the β and γ values were increased by 260% and 175 % respectively.

Both the β and γ values for non-halogenated tetramethylporphyrin were significantly decreased when compared to non-halogenated porphyrin. Even though placing halogens on the pyrrole increased the second and third order polarizabilities, the best β and γ values occurred when halogens were placed on the pyrrole bridge, in positions B and D. The β value dramatically increased 17-fold (when compared to the non-halogenated tetramethylporphyrin). The γ value for this molecule (VIII) was also increased by 60%.

The β value for non-halogenated tetraphenylporphyrin was 34% lower than non-halogenated porphyrin. However, the γ value was increased by 170%. Even though the γ values for all the tetraphenylporphyrin molecules were fairly high (>41 x $10^{-61}Cm^4V^3$), only one tetraphenylporhyrin compound (molecule XIX) showed a promising β value of 65.3 x $10^{-51}Cm^3V^{-2}$.

Conclusion

Although halogens have the capability of greatly enhancing the second and third order polarizabilities, their positions is crucial. For the porphyrin and tetramethylporhyrin molecules, the best β and γ values occur when the halogens are located on the pyrrole bridge. Please refer to figure 1, for the molecule designations. Molecules II and VIII have the best β and γ values among the molecules studied. Molecule II is a F substituted porphyrin and molecule VIII is a F substituted tetramethylporphyrin molecule.

Both of these molecules may be capable of generating large second and third harmonics. However, VIII may be problematic due to its large angle for the projection of β onto μ. On the other hand, XV through XXXI result in very good γ values. The γ value of these tetraphenylporphyrin molecules were barely affected by the halogen location.

A Novel Method for Investigating Phase Disturbances

Rex L. Blair Jr.

Photonics Research Center
U. S. Military Academy
West Point, NY 10996

Faculty Advisor:

Thomas R. Moore

We report on a new, simple method for examining phase disturbances. In our method, we use the finite time response of two beam coupling in a photorefractor to obtain images of rapidly varying phase disturbances. We show both theoretically and experimentally that, when using our technique, there is a simple relationship between the intensity distribution of the image and the phase disturbance. We use this relationship to interpret images of phase phenomena, and we demonstrate the usefulness of this technique by analyzing the flow of butane from a small nozzle.

INTRODUCTION

There are many methods available to analyze phase disturbances such as fluid flow, gas flow, and other atmospheric disturbances.[1] We have developed a new, optical method for examining such phase disturbances. Our method has several advantages over other phase-contrast methods, such as Schlieren photography, in that our method is robust, can be used to analyze large phase changes, and provides for simple analytic interpretation of the image. In our method, we use the finite time response of two beam coupling in a photorefractor to obtain images of rapidly changing phase disturbances.[2] So that we may analyze these phase disturbances, we derive a relationship between recorded intensity and the phase disturbance. We show both theoretically and experimentally that, when using our method, there is a simple relationship between the recorded intensity and the phase disturbance. We also demonstrate the usefulness of this method by analyzing gas flow through the small nozzle of a butane lighter.

Our apparatus for investigating phase disturbances is a variation of that previously used by others in visualizing phase disturbances.[3] It produces images that clearly depict phase changes as intensity variations. As illustrated in Figure 1, we direct the beam from an Ar^+ laser ($\lambda = 514.5$ nm) through a spatial filter and collimate the beam with a diameter of approximately two inches. After propagating through a sample region, the beam is then focused through a photorefractor (a SBN:Ce crystal) where the process of two beam coupling depletes the sample beam. The sample region is then imaged on to a CCD array.

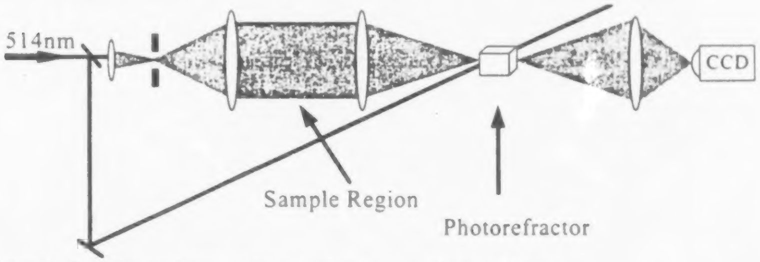

Figure 1. Experimental setup used to capture images of phase changes.

Using this arrangement, we can capture real-time images of phase changes in the sample region. An example is shown in Figure 2, which is the image of gas flow from an ordinary

Figure 2. The image of gas flow from a butane lighter.

hand-held butane lighter viewed through the experimental arrangement shown in Figure 1. This method has been previously reported,[4] however the interpretation of images such as that shown in Figure 2 has to our knowledge never before been possible.

THEORY

To interpret such images as that shown in Figure 2, we must develop a relationship between the recorded intensity distribution and the phase change occurring inside the sample region. The process of two beam coupling in photorefractors is well understood. It begins with the interference between the two beams within the crystal.[2] The intensity distribution inside the photorefractor causes electric charges inside the crystal to move from regions of higher intensity to regions of lower intensity. Because the regions of charge are separated within the photorefractor, an electric field is formed. This spatially varying electric field produces an index grating within the photorefractor via the Pockels effect. As a result of this index grating, light is scattered from the signal beam into the pump beam. In Figure 3 we graphically depict how the intensity affects the electric charges, electric field, and the index of refraction inside the photorefractor. Note that the electric field and the index of refraction are out of phase with the intensity and the charge distribution by a quarter of a wavelength. This phase difference is responsible for the process of two beam coupling.

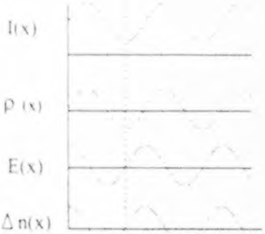

Figure 3. Plot of the intensity (I), charge distribution (ρ), electric field (E), and index variation (Δn). (after reference 2)

It is important to note that photorefractive two beam coupling is a dynamic process, and that the index grating is continuously changing and adapting to changes in the two beams. Whenever the phase of intensity of either beam is altered, the photorefractor changes as well. However, at the intensity typically used in the laboratory, the photorefractor requires a few seconds to respond to any changes. When a phase change in the signal beam occurs faster than the crystal can adapt, we can consider the grating inside the photorefractor to be static. Since we are interested in analyzing rapidly varying phase changes, from this point forward, we will consider the index grating in the photorefractor to be static.

It can be shown that the following equations apply to a static, thick grating:[4]

$$\frac{\partial A_p}{\partial z} = i\kappa A_s \exp(i\varphi) \qquad (1a)$$

and

$$\frac{\partial A_s}{\partial z} = i\kappa A_p \exp(-i\varphi), \qquad (1b)$$

where A_p is the amplitude of the pump beam, A_s is the amplitude of the signal beam, κ is a constant dependent upon the specific photorefractor and the geometry, and φ is the grating phase shift in the photorefractor (i.e. the phase shift between the intensity modulation and the phase grating). Assuming that the phase of the pump beam and the index grating is zero at $x = y = 0$, the boundary conditions are given by:

$$A_p(0) = |A_p(0)| \qquad (2a)$$

and

$$A_s(0) = |A_s(0)| \exp[i(\varphi + \Delta\varphi)], \qquad (2b)$$

where $\Delta\varphi$ is the unknown phase change imposed on the signal beam within the sample region. Using equations (1) and (2), it can be shown that the intensities of the beams upon exiting the crystal are given by:

$$\frac{I_s(L)}{I_p(0)} = \left(\frac{1+\beta}{2}\right) - \left(\frac{1-\beta}{2}\right)\cos(2\kappa L) - \sqrt{\beta}\,\sin(2\kappa L)\sin(\varphi + \Delta\varphi) \qquad (3a)$$

and

$$\frac{I_p(L)}{I_p(0)} = \left(\frac{1+\beta}{2}\right) + \left(\frac{1-\beta}{2}\right)\cos(2\kappa L) + \sqrt{\beta}\,\sin(2\kappa L)\sin(\varphi + \Delta\varphi) \qquad (3b)$$

where

$$\beta = \frac{I_s(0)}{I_p(0)}, \qquad (4)$$

and L is the length of the grating inside the photorefractor.

When only changes in phase occur within the sample region (i.e., β is a constant) then, except for the argument of the sine function, all of the terms in equations (3) are constants. Also, by setting $\varphi = \pi / 2$, as is commonly the case for most photorefractors, the sine function becomes a cosine function. Assuming maximum two beam coupling, we then have the following equation, relating the observed intensity to the phase change in the sample region:

$$\frac{I_s(L)}{I_p(0)} = \left(\frac{2\beta}{1+\beta}\right)[1 - \cos\Delta\varphi]. \qquad (5)$$

Equation (5) explicitly describes the relationship between the change in phase or amplitude of the signal beam and the recorded intensity for the case of optimal two-beam coupling. For non-optimal coupling equation (3a) must be used, however, the functional form remains cosinusoidal in $\Delta\varphi$.

Equations (3) also indicate a nonlinear dependence on a change in the intensity of the input beam. That is, if β is not constant, but Δφ is, a change in intensity will be recorded at the output of the apparatus. This relationship between $I_s(L)$ and β cannot be reduced to a simple formula, as can be done with Δφ.

EXPERIMENT

We have experimentally verified equation (4) using a modified version of the experimental arrangement shown in Figure 1. As shown in Figure 4, we modified the configuration from that shown in Figure 1 by placing a Pockels cell into our sample region, and replacing the CCD with a photo-diode.

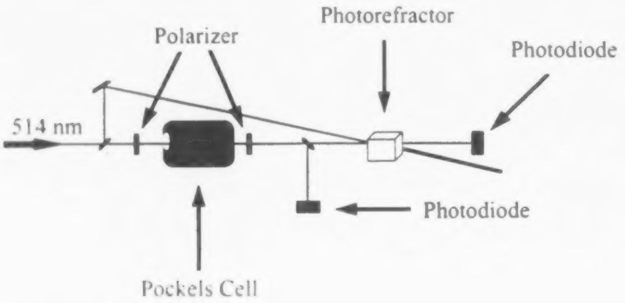

Figure 4. Experimental Setup

To investigate the relationship between Δφ and $I_s(L)$ we do not use the Pockels cell in the traditional manner. Rather, we orient the crystalline axes of the cell parallel to the polarization of the light, thus allowing the introduction of a pure, known shift in phase into the signal beam. To investigate the dependence of $I_s(L)$ on β, we orient the Pockels cell in the usual manner, allowing the introduction of a pure, known intensity variation of the signal beam.

RESULTS AND DISCUSSION

Results of experiments demonstrating the relationship between the intensity and Δφ are shown in Figure 5, where we plot the intensity of the signal transmitted through the photorefractor as a function of the applied phase shift. Also plotted in Figure 5 is the fit to equation (5). Note the excellent agreement between theory and data.

The dependence of $I_s(L)$ on β is shown in Figure 6 using the experimental setup shown in Figure 4 (with the Pockels cell oriented in the traditional manner). The line is a fit to the data we obtained in the experiment using equation (3a). Again, note the excellent agreement between theory and data.

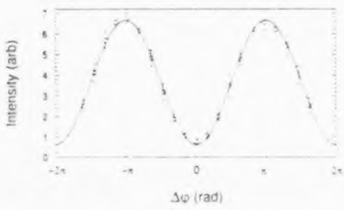

Figure 5. Sample beam intensity of the photorefractor plotted against Phase shift.

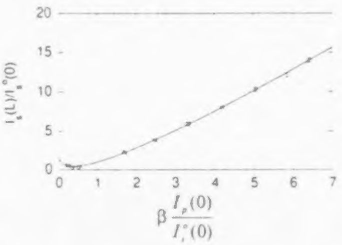

Figure 6. Intensity of the transmitted beam plotted against the intensity of the incident beam.

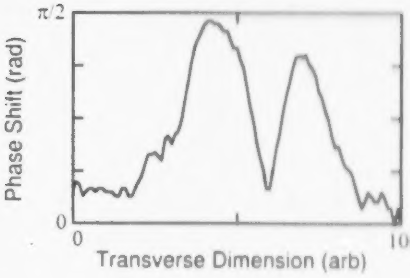

Figure 7. Phase shift versus the transverse dimensions using intensity data derived from Figure 2.

Using equation (3a) and the fit obtained from the data shown in Figure 5, we can deconvolve the intensity data from the picture in Figure 2 to a graph that depicts the phase shift versus the transverse dimensions of the beam. This is shown in Figure 7. Thus, we have determined the phase aberration induced by the flowing gas *in situ*, without affecting the flow in any way.

CONCLUSION

In conclusion, we have developed a new, simplified method for analyzing phase disturbances. We have shown that when using our technique, the observed intensity and the phase change have a cosinusoidal relationship. Unlike most phase-contrast methods, our method requires no expansion of the phase change to relate the recorded intensity to the actual phase change in the sample region. Therefore, our method can be used to analyze large phase changes. Finally, we have demonstrated the utility of this new technique by measuring the phase delay due to a gas jet.

An X-ray and Optical Study of Galaxies in Pairs

Sarah Cousineau and Mark Henriksen

Department of Physics
University of North Dakota
Grand Forks, ND 58202

We have obtained X-ray (L_x) and blue luminositities (L_b) for a sample of 57 pairs of galaxies of mixed morphology, including spiral galaxy pairs, elliptical galaxy pairs, and pairs consisting of one elliptical and one spiral galaxy (mixed pairs). We find a strong relationship between L_x and L_b for the spiral and elliptical pairs, with L_x dependent on L_b. We also find clear evidence for increased levels of star formation for galaxies in pairs compared to isolated galaxies. Furthermore, data from the elliptical pairs as well as some of the mixed pairs suggest that elliptical galaxies are the products of mergers within small groups of galaxies.

INTRODUCTION

Galaxies are enormous, gravitationally bound ensembles of gas, dust, and stars. They are the residence of almost all stellar objects, including black holes and dark matter, and are spread throughout the universe in various shapes and sizes. Galaxies rarely travel solo and are often members of small groups of galaxies or larger structures called clusters. These local groups are said to be "virialized", or existing in an equilibrium state with respect to gravitational potential. The combined mass of the group, including both the visible and non-visible matter, exerts control over the intergalactic medium in the galaxies; thus, the dust and gas in a galaxy is bound to the group as much as it is to the individual galaxy.

Two distinctly different classes of galaxies exist, namely elliptical and spiral galaxies. Elliptical galaxies are spherically shaped objects dominated by old stars and are essentially devoid of interstellar medium. The interstellar medium, i.e., the gas and dust found in galaxies is the fuel for stellar birth, without which a galaxy cannot produce new stars. Therefore, elliptical galaxies are not thought to be very active in their star formation roles. Quite in contrast to the ellipticals, spiral galaxies are highly structured, disked-shaped galaxies with central bulges and outward spiraling arms. Spirals are identified with high concentrations of interstellar medium and are consequently the breeding grounds of new stars. Stellar birth serves to heat the nearby interstellar medium, resulting in large portions of hot gas throughout the galaxy.

Although elliptical and spiral galaxies have identifying properties of composition and stellar activity, these properties are subject to alteration due to galactic environment and history. We investigate these two parameters, i.e., stellar activity and abundance of hot, interstellar gas, to evaluate the effect of pairing on galaxies of various morphology class. Since young, new stars emit blue light, stellar activity is measurable through a galaxy's luminosity in the blue part of the electromagnetic spectrum (L_b). The heated, interstellar component gas in galaxies is a major contributor to the X-ray luminosity (L_x), along with X-ray binaries and supernovea remnants, all indicators of star formation.

We have surveyed and analyzed these parameters for over 50 pairs of galaxies using previously collected optical data and sensitive X-ray observations of the galaxies. Albeit that X-ray satellites have focused their attention on a few pairs of galaxies, there are not nearly enough targeted pairs to constitute a statistical sample. Our sample was achieved by hunting through the X-ray image field of the ROSAT PSPC satellite for chance observations of galaxy pairs. With a gold mine of findings, this study presents the first X-ray analysis of galaxies in pairs.

DATA ANALYSIS

X-ray Luminosity

Our sample of 57 galaxy pairs were located in X-ray images taken by the PSPC detector on board the ROSAT satellite. The PSPC spent approximately four years in orbit capturing X-ray pictures of the universe through a one degree viewing lens. The satellite was programmed to target large, visible objects in the nearby universe, as well as an all-sky snapshot survey. Images collected from the detector during its lifetime have been placed in NASA data archives and made available to the public. It was from these archives that we obtained our data.

Data analysis began by locating the galaxy pairs in the ROSAT image fields. This location was our source region and we captured it with a circle of radius > 100 Kpc (300, 000 light years), chosen to include the X-ray emission from both galaxies. Four sourceless regions were similarly captured and defined as background regions. X-ray counts were found for each of the regions and the error taken as the square root of the counts (Eq. 1). The net counts for the source region was found by subtracting the area-normalized average background counts from the total counts in the source region (Eq. 2). The error for the net counts was calculated via Equation 3

$$\sigma_t=(C_t)^{1/2},\ \sigma_b=(C_b)^{1/2},\ \text{where } C_s = \text{total counts},\ C_b = \text{background counts} \qquad (1)$$

$$\text{net counts} = (C_t) - (C_b)\,(A_1/A_2) \qquad (2)$$

$$\sigma^2_{net} = \sigma^2_{total} + \sigma^2_{back} \qquad (3)$$

Positive net counts resulted in a source detection, while negative counts were converted to upper limits. Upper limits were calculated as 3σ + total source counts. This ensures with 99% confidence that the source is below this level.

Positive net counts were used to derive a best-fit spectrum for the source which included as parameters the temperature, absorption coefficient, and abundance of elements. X-ray fluxes were calculated from this spectrum and converted to luminosity using the distances to the galaxies (Eq. 4). Distances are given inversely as Hubble's constant (H_0), a constant which measures the expansion of the universe and is currently known within a factor of two. For this study, we assumed the value H_0=50 Km s^{-1} Mpc^{-1}. Any comparisons made to other studies also utilize this value.

$$L_x=4\pi D^2 \times \mathit{flux},\ D\sim(1/H_0) \qquad (4)$$

X-ray analysis included accounting for several complications due to the lack of a "flat field" in the image screen. To correct for these problems, NASA has available an exposure map image which displays the X-ray collection pattern for each image. Corrections for locations of the regions on the image field were made using this file.

Optical Luminosities

Optical luminosity in the blue part of the electromagnetic spectrum were calculated using the apparent magnitudes and redshifted velocities of the galaxies listed in the Catalog of Isolated Galaxy Pairs in the Northern Hemisphere (Karachentsev,1972) in conjunction with Solar luminosity and magnitude (Eq. 5-7).

$$D = V/H_0,\ H_0 = 50 \text{ Km s}^{-1} \text{ Mpc}^{-1} \qquad (5)$$

$$M_g = 5 - 5\text{Log}[D] + m_a \qquad (6)$$

$$M_g - M_s = 2.5\text{Log}[L_s/L_b],\ M_s = 4.5,\ L_s = 3e39 \text{ (ergs/sec)} \qquad (7)$$

RESULTS AND DISCUSSION

Our final sample of data included X-ray and blue luminosities for 24 pairs of spiral galaxies, 15 pairs of elliptical galaxies, and 18 mixed pairs of galaxies. The data was analyzed using Survival Analysis (ASURV), a statistical package adopted from the insurance agency for use in astronomical research. The variables in each subset of pairs were tested for correlations, and linear regression models were run to obtain mathematical fits to the data. Moreover, comparisons were made between each subset and a corresponding set of isolated galaxies.

Spiral/Spiral Pairs

Correlation test between L_x and L_b for the spiral galaxy pairs show a 99% probability that the variables are linearly related, with L_x dependent on L_b. This indicates that the amount of hot gas in a galaxy is indeed dependent on the rate of star birth. This conclusion is further confirmed for isolated spirals, where L_x and L_b are again found to be linearly related (Fabbiano et. al, 1987). It is found, however, that the range of values of blue luminosities for spirals in pairs is smaller than that of isolated spirals, and resides at the upper end of the spread. The small relative number of dim spirals in pairs suggests that, whereas some isolated spirals may not be very active in stellar formation, spirals in pairs are generally swarming with stellar birth. Following a similar trend, X-ray luminosities are found to be higher in pairs than in isolated spirals. The relationship between X-ray and blue luminosity for the pairs is similar to that of isolated spirals, indicating that the increase seen in X-ray luminosity is due to high levels of stellar activity which heats the surrounding medium, causing it to shine in the X-ray. Gravitational interactions in the pairs are the likely source of this stellar phenomenon.

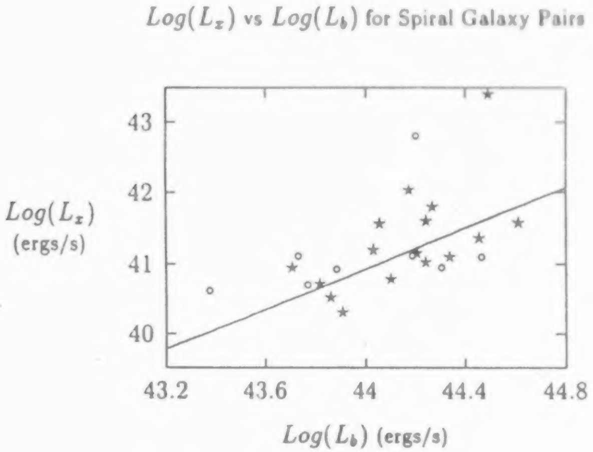

Fig. 1. X-ray vs. blue luminosity for spiral galaxy pairs. Stars represent detections, and open circles represent upper limits.

Elliptical/Elliptical Pairs

Similar to the spiral pairs, L_x and L_b for elliptical pairs of galaxies are shown to be linearly related with a correlation probability of 99%. X-ray and optical luminosities for isolated ellipticals are well correlated (Eskridge et al, 1994), again verifying that the amount of hot gas is determined by the level of star formation. Blue luminosities are shown to be higher for ellipticals in pairs than isolated ellipticals, once more suggesting higher levels of star formation for galaxies in pairs than isolated galaxies. X-ray luminosities were found to be several orders of magnitude higher for pairs than for isolated galaxies. Moreover, the relationship between blue luminosity and X-ray luminosity for the pairs was not consistent with that of the isolated set of galaxies. The fit to the data for L_x vs L_b for the pairs follows a much steeper slope than that of isolated galaxies, showing that X-ray luminosities for pairs increases much more quickly with increasing blue luminosity than isolated ellipticals. Thus, there is an extra component of X-ray, seen most prominently in optically luminous pairs, which suggests that many of the elliptical pairs are the product of mergers of small groups of galaxies. Mergers would trigger new star formation, accounting for the high levels of blue luminosity. The intergalactic medium, separated from the halo of early-type galaxies would remain after merger, producing X-ray emission around the newly formed pair characteristic of a group of galaxies. It has been shown that the velocity dispersion of a group is related to its corresponding level of X-ray luminosity (Ponman et.al, 1997). However, correlation tests between X-ray luminosity and velocity dispersion for pairs of ellipticals do not show a relationship between the two parameters. We deduce that the mergered galaxies have not had sufficient time to achieve an equilibrium state.

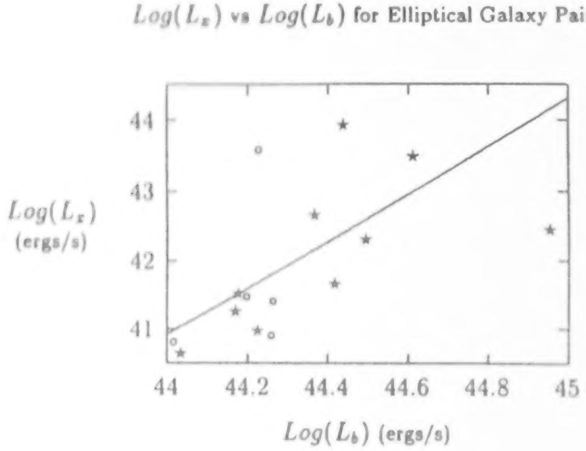

Fig. 2. X-ray vs. blue luminosity for elliptical galaxy pairs. Stars represent detections, and open circles represent upper limits.

Elliptical/Spiral Pairs

Mixed pairs of galaxies comprise the only set of pairs that do not show a clear correlation between X-ray and blue luminosity. The correlation breaks down due to a few pairs of galaxies with high X-ray luminosities but low relative blue luminosities. These appear very much like the elliptical set of pairs, but with low blue luminosities. The remainder of the sample corresponds well with the spiral set of pairs. The possibility exists that the mixed pairs with low L_b and high L_x are systems which have had a merger some time in the past, so that star formation has faded but group X-ray emission remains.

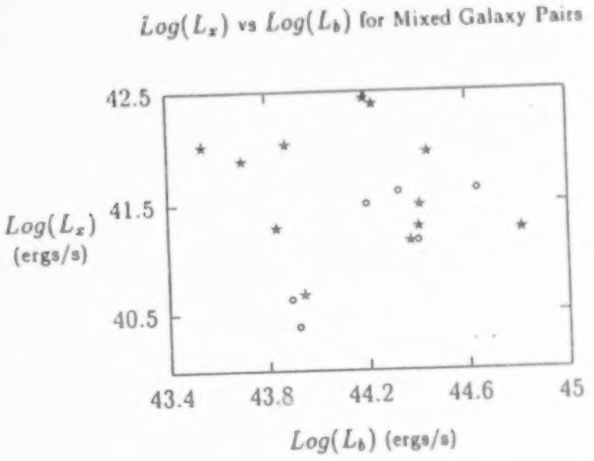

Fig. 3. X-ray vs. blue luminosity for mixed galaxy pairs. Stars represent detections, and open circles represent upper limits.

CONCLUSIONS

A survey of X-ray and blue luminosities of 57 pairs of galaxies has resulted in the first complete set of X-ray data on galaxies in pairs. Comparisons to isolated galaxies, along with statistical analysis of the data, have enabled us to single out unusual behavior among pairs of galaxies and gain insight into the history and current on going of the pairs. It is found, in general, that the amount of diffuse, hot gas in a galaxy is predicted by the level of star formation. Galaxies in pairs are shown to have higher rates of star formation than isolated galaxies, and correspondingly high levels of hot gas. These results are predicted by the increase seen in L_b and L_x for the galaxies in pairs compared with isolated galaxies. Gravitational interactions account for the increase in star formation observed in the spiral pairs. The elliptical pairs, however, exhibit an additional component of X-ray which makes gravitational interactions alone an unlikely candidate for their unusually high levels of X-ray luminosity. We theorize, instead, that the ellipticals pairs, as well as some of the mixed pairs, are the descendants of three or more galaxies which have merged together to leave only a pair. We further conclude that the there has not been an adequate amount of time since the mergers for the pairs to reach virial equilibrium.

Optically Driven Pendulum

Dr. Randall Peters and LTC Thomas Moore

A physical pendulum with adjustable period has been studied in free decay, and also when excited at very low levels with a laser. Using a novel capacitive sensor to measure displacement, it was found that the motion of the pendulum depends significantly on the material properties of strategically placed samples, that are load bearing members of the pendulum structure. Placed in pairs, on opposite sides and near the center of mass; the samples, under compression, are exposed sequentially to the laser. Differential thermal expansion causes periodic lateral shifts in the center of mass, which is the driving mechanism. The frequency of the laser drive is adjustable, by means of an electronic timer connected to shutters. For samples of single crystalline lithium fluoride, the motion involves complicated hysteresis. Moreover, the damping constant can be negative, meaning that the pendulum oscillates as a result of stimulated processes involving defect structures of the LiF.

BACKGROUND

The pendulum is probably the most studied and among the best understood mechanical systems. For centuries it has been the basis for a variety of physical phenomena investigations. Most of the early work with pendula involved observations using a simple timepiece. Since about 1990, new measurement technology has permitted the study of physical pendula with very low amplitudes and long periods of oscillation. These new sensors enable the physical pendulum to be an instrument for the study of internal friction involving defect structures.

This paper seeks to demonstrate the relevance of physical pendula to the study of internal structures and how internal friction can affect the behavior of a pendulum. It will be shown that the popular equation of motion, that of the simple harmonic oscillator in free decay with damping, does not apply to all physical pendula. Although the classical equation for a simple harmonic oscillator with damping predicts that the log decrement of the amplitude of oscillation (L.D.) of a physical pendulum is proportional to the period (T) to the first power, we have found, for the pendulum studied, that the L.D. is more nearly proportional to T squared. Additionally, we have found that activity internal to samples placed in the pendulum structure is responsible for much of the unexpected behavior of the system.

THEORY

Traditionally, the solution to the equation of motion of a damped pendulum is

$$\theta(t) = \theta_o e^{-\beta t} \cos(\omega t + \phi), \qquad (1)$$

where $\theta(t)$ is the displacement at time t, θ_o is the maximum amplitude, β is the viscous damping term, $\omega = (\omega_0{}^2 - \beta^2)^{1/2}$, and $\omega_0 = (mgd / I)^{1/2}$, in which d is the distance from the axis to the center of mass, m is the mass, g is the gravitational constant and I is the moment of inertia about the axis. Using θ at two different turning points, one period apart, we obtain

$$\theta(t = 0) = \theta_o e^{-\beta(0)} = \theta_o \qquad (2)$$

$$\theta(t = T) = \theta_o e^{-\beta T} \qquad (3)$$

from which the log decrement is found to be proportional to T:

$$L.D. = \ln(\frac{\theta_o}{\theta_T}) = \beta T. \qquad (4)$$

Contrary to the above prediction, our experimental results show that the traditional viscous damping term is not adequate. So, we resort to a phenomenological treatment in which (1) is rewritten as:

$$\ddot{\theta} + \gamma\dot{\theta} + \omega_o^2\theta = 0, \qquad (5)$$

Were γ is not a constant, but rather $\gamma = c / \omega_0$. Although sometimes nearly constant, c can vary with changes in molecular structure of the pendulum samples. With c constant, L.D. is proportional to T^2, rather than the commonly accepted T. Some of our data, as well as that of others, are nearly consistent with a quadratic dependence on T of L.D. [1]. However, as contrasted with earlier studies, our research is concerned with low level oscillations which are sometimes discontinuous.

The damping most important to our investigation is due to anelasticity. When a crystalline material is cycled in stress and strain, some molecular bonds can break and internal grains can rearrange, a type of molecular "musical chairs." These irreversible processes generate heat internal to the system. Because the strain in the material normally lags in phase behind the stress, there is a mechanism for damping. It is also possible, under some circumstances, to have the strain lead in phase. This negative damping case results in "self-oscillation," meaning that the pendulum will oscillate without an external driving force. Understanding the damping mechanism from first principles for anelastic damping is not as simple as with viscous damping. It is dependent on many variables, not the least of which is the geometry of the structure being used and how the material was prepared. Therefore, each case is unique.

Another consideration of our study was the relative significance of driving frequency versus natural frequency for the pendulum when driven. Classically, when an oscillator is driven, the equation of motion becomes non homogeneous:

$$\ddot{\theta} + \gamma\dot{\theta} + \omega_o^2\theta = \alpha(t) \qquad (6)$$

and its steady state response as a function of the periodic drive is:

$$\theta \propto \frac{1}{\sqrt{(\omega_D{}^2 - \omega_o^2)^2 + (\gamma\omega_D)^2}} \cos(\omega_D t + \phi) \qquad (7)$$

where ω_D is the drive frequency and ω_0 is the natural frequency of the undamped oscillator. As the drive frequency approaches the natural frequency, ω_0, the amplitude approaches a maximum. Additionally, an oscillator driven at a frequency other than its natural frequency will experience "beating" as it tries to oscillate at both frequencies. Classically, this transient beating will eventually die out and the drive frequency will dominate.

EXPERIMENTAL SYSTEM

The research presented in this paper focuses on pendulum motion at very low levels and lower frequencies than are usually studied. These pendulum motions are larger than atomic scale motions and smaller than macro-scale motions; they are sometimes said to be in the meso-realm and are invisible to the human eye. Because the motions are on such a small scale, the sensors used to measure them are very important.

In conducting this research, the authors used a new measuring device, the symmetric differential capacitance (SDC) transducer [2]. A small metallic plate is fixed to the pendulum arm, and as the pendulum swings, the metal plate travels back and forth between static electrodes. As the plate moves, a signal proportional to the pendulum displacement is sent through an analog-to-digital converter to an IBM computer, which can display and store the wave forms. The SDC sensor can resolve motions of the pendulum on the order of 1 μ radian. This is sufficient to observe interesting phenomena in the meso-realm. Additionally, the computer can store permanent records of the pendulum motion, which is essential for data analysis.

The period of the pendulum is adjustable from 1s to 10s. Figure 1 shows the pendulum design. Although the illustration shows LiF samples placed between the masses, other materials were also studied, including aluminum, rubber, and brass. The position of the top mass along the support tube is variable, which allows one to change the natural period of the pendulum. The pendulum and sensors were placed under a bell jar to reduce the effect of air currents on the system. The pendulum rests on a standard pneumatic optical bench to isolate the system from seismic events. Finally, a Faraday shield, consisting of a grounded mesh wire surrounds the bell jar and pendulum, to stabilize the electronics. This minimizes false readings caused by stray capacitance changes and electromagnetic disturbances external to the system.

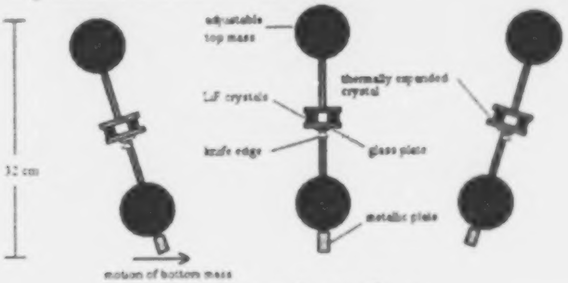

Figure 1: Pendulum Design

A 10 Watt Argon ion laser, operating at a wavelength of 514 nm, provided the drive. The laser and optical elements were fixed to a separate optical bench so as not to disturb the pendulum. A timing circuit controlled two shutters and allowed the laser to heat the lithium fluoride, alternating from one crystal to the other, at an adjustable frequency.

RESULTS

Expecting the damping of this system to be of particular interest, we began our studies by measuring free decay log decrements with LiF samples. Using the laser, we built up oscillations to about 200 μ radians peak to peak. We then measured amplitudes as a function of time. We found that the log decrement at a given pendulum frequency varied by 30% or more in some cases. Some examples are shown in Figure 2.

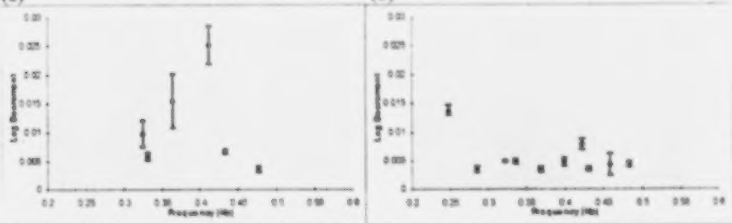

Figure 2: Log Decrement plot for the pendulum with LiF samples (a) and irradiated LiF samples (b)

Figure 2 shows log decrement plots for the pendulum with two different sets of LiF crystals. One set of crystals had been irradiated with 10^8 rad (water) of gamma radiation, while the other had not. As can be seen from each of the two cases, the log decrement of the pendulum using LiF samples shows a peak around 0.40 Hz to 0.45 Hz. However, the peak is better defined in the case of non-irradiated crystals. This observation is consistent with Frankl and Read [3]. Similar data taken with samples of brass, aluminum, and rubber exhibit less variability than that of LiF. Figure 3 provides a

1441

comparison with Al. In all of these measurements (LiF, Al, brass, and rubber) the log decrement was found to be more closely proportional to T^2 than to T.

Several long records of the pendulum motion were taken in which free decay was preceded by laser driving of the LiF. For those records, the pendulum was driven to an amplitude of approximately 200 μ radian peak to peak, then allowed to decay. Although the mean position of the pendulum sometimes shifted during a record, the peak to peak features of free decay appeared normal for several minutes after the driving had ceased. However, some records showed negative damping, beginning five to fifteen minutes after the drive had stopped.

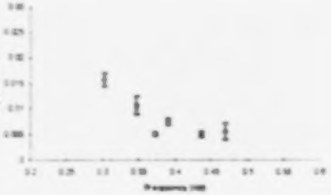

Figure 3 Damping of Pendulum with Al Samples

Figure 4 shows an example of negative damping. For most cases in which negative damping developed, the increase in amplitude began to first appear after the amplitude of oscillation had decayed to the order of 10 μ radian, which is just above the noise level for the measuring device. Analysis of the power spectrum confirms that this oscillation is at the natural frequency of the pendulum, and is not simply random motion or electronic malfunction.

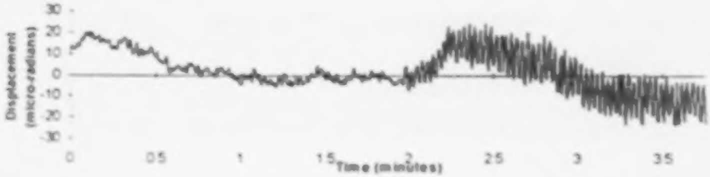

Figure 4: Free decay record of the pendulum showing a smooth rise in amplitude, signifying a negative damping process.

Other records show discrete jumps in the pendulum motion. Again, these were cases in which the free decay was preceded by laser drive. The jumps usually occur with a sudden anti symmetric shift in the mean position, as illustrated in Figure 5, where three such jumps are readily seen.

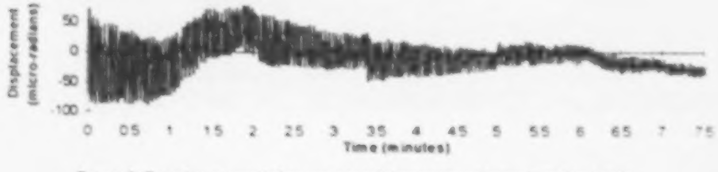

Figure 5: Free decay record showing several discontinuous "jumps" in amplitude

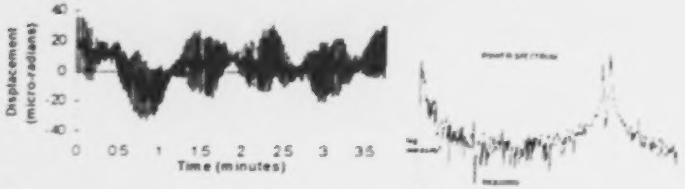
Measurements while the laser drive was still active also led to unusual cases. By comparing these to the classically expected steady-state response of a driven pendulum, we attempted to discover effects of the samples on the response of the pendulum. Classical theory predicts that beating will occur when the drive frequency does not equal the pendulum's natural frequency. The beat amplitude should decrease exponentially with time, and eventually disappear. In this final steady-state, the pendulum should oscillate at the frequency of the drive mechanism, as opposed to its natural frequency. We found this not to be the case in all situations.

Several interesting cases emerged from our data involving the driven pendulum with LiF samples. In one case, we drove the pendulum at a frequency of 0.565 Hz, where the pendulum had a natural frequency of 0.535 Hz. Figure 6 shows a $7\frac{1}{2}$ minute record of the oscillation of the pendulum and the corresponding power spectrum. This record was taken after the laser had been driving the pendulum for 30 minutes. One can easily see the beating as predicted by classical theory. The surprise, however, is that the beating remains long after it should have died out.

Using a log decrement of 0.004, one can readily estimate the time required classically for the beat amplitude to decay to $^1/_{10}$ of its initial amplitude. For a period of 1.87 seconds this should happen after 18 minutes of driving. In the case shown, the beating after over 30 minutes is nearly the same as it was initially.



(a) (b)

Figure 6: Record of a driven pendulum (a) and its accompanying power spectrum (b)

In an effort to explain the unusual oscillations of our pendulum, we theorized that the LiF crystals must somehow store and then release energy. As a starting point, we attempted to detect any fast photomechanical effects in the crystal at the time of laser turn-on. Because thermal expansion alone cannot explain the anomalous behavior, it is possible that an immediate restructuring of the crystal might take place when bombarded by photons from the laser.

To detect the postulated photomechanical effect, we built a Michelson interferometer using a Helium Neon laser and placed a LiF crystal in the beam path. We monitored the output of the interferometer with a fast photo diode. The diode was connected to an oscilloscope with sufficient bandwidth to observe any fast transients. Since none were seen, some other mechanism must be responsible for the erratic and unpredicted behavior that we have observed.

CONCLUSIONS

One explanation for the pendulum's anomalous behavior is that the defect structures involving pinned dislocations of the LiF crystals store energy, and then release that energy in response to stress that the pendulum imposes on the crystals. This seems to explain the cases where negative damping occurred several minutes after the drive was turned off. This explanation does not seem unlikely since gamma irradiated LiF is known to exhibit thermoluminescence. Samples of LiF bombarded with radiation can be placed in an oven and heated until they give off photons [4]. In the present case, it is postulated that the pendulum provides periodic low-level stress that eventually triggers the release of energy stored in the defect structures of the LiF crystals. The specific mechanisms whereby triggering occurs is not presently known. An attempt will be made in future experiments to understand the postulated defect dynamics.

Cadmium zinc telluride single crystals were grown by physical vapor transport method with a 970 °C growth temperature and a 8 mm/day growth rate. Atomic force microscopy was employed to reveal the surface morphology of crystal along growth direction. The crystal revealed smooth surfaces, in sub-nano-meter range, and lack of structural defect and second phase features along growth direction indicating that its overall high quality in terms of defect and chemical homogeneity. Some precipitates have been observed at the beginning of crystal growth, and they might induced from the initial unstable growth conditions by higher Cd vapor pressure.

INTRODUCTION

Cadmium zinc telluride (CdZnTe) was first developed as a substrate material for epitaxial growth of HgCdTe film, which is infrared detector material, due to its lattice match. In the past few years, CdZnTe has also been investigated extensively for its potential usage as radiation detector operated at room and elevated temperature (Egarievwe, Chen, Burger, James, Lisse, 1996; Chen, Shi, Morgan, Collins, Burger, 1997). Commercially available bulk CdZnTe crystals are usually grew by Bridgman or high pressure Bidgman (growth from melt phase) (Triboulet, Neu and Fotouhi, 1983; Bruder, Schwartz, Schmitt, Maier and Möller, 1990; Cheuvart, El-Hanani, Schneider and Triboulet, 1990) which often induced structure defect (strain, stress) and deviation from stoichiometry due to the high growth temperature and higher partial pressure of Cd compared to Zn and Te. Improved growth conditions with lower growth temperature to limit defect formation and composition variation may be achieved by employing physical vapor transport method. Physical vapor transport (PVT) growth method is accomplished by first vaporization of material, and then re-solidification back to solid in a single crystalline form. The growth temperature employed by PVT method is lower than the melting temperature of the material. Therefore the chemical variation and defect formation on the growth interface and post-growth cooling is expected to be lower than Bridgman method. Atomic force microscopy is a real-time imaging technique that can produce topographic images of a surface with atomic resolution in three-dimension. The information that derives form AFM image can be correlated to material processing conditions. In CdZnTe system, defect formation and stoichiometry variation may be present as precipitation or inclusion. A typical example for CdZnTe system is the cleavage surface exhibiting inhomogeneities in the form of Te-rich inclusions. These Te-rich inclusions originate from the higher vapor pressure of Cd during crystal growth leading to a Te-rich composition in the final stage of crystal growth. These inclusions has been observed by atomic force microscopy (AFM) to be in the order of nm size depending on various growth conditions (Palosz, George, Collins, Chen, Zhang, Hu and Burger, 1996). In this study, PVT crystal growth method was employed to grow high quality, in terms of purity and stoichiometry, $Cd_{0.8}Zn_{0.2}Te$ single crystal. Atomic force microscopy was also employed to reveal the surface morphology of as-grown crystals and its correlation with crystal growth conditions.

EXPERIMENTAL

High purity quartz tubing was used as ampoules for material processing and crystal growth. The ampoules were pre-cleaned with aqua regia and rinsed with distilled water. The ampoules were then outgassed under 10^{-7} Torr vacuum at 1000 °C. The CdTe and ZnTe source materials were purchased from Alfa, Co. with 5N (99.999%) purity. The ternary compound, $Cd_{0.8}Zn_{0.2}Te$ was synthesized from stoichiometric amount of CdTe and ZnTe at 1000 °C for 2 weeks. The ternary compound was then ground into powder and loaded into crystal growth ampoule and sealed under 10^{-7} Torr vacuum. The crystal growth process was performed in a three-zone furnace and the temperature gradient were controlled by three separate temperature controller. Figure 1. shows the configuration of crystal growth apparatus employed in this study. The left side of Figure 1 shows the configuration of the crystal growth system, and the right side shows the temperature profile inside the growth furnace. The growth temperature was 970 °C with a temperature difference of 10 °C than the temperature of source material. The crystal growth

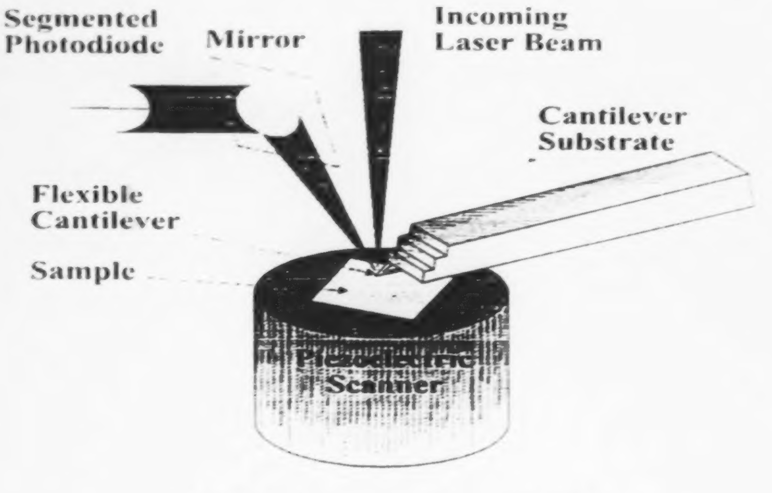
ampoule was hang in a fixed position while the furnace was traveling upward at a speed of 8 mm/day (crystal growth rate).

Atomic force microscopy (AFM) was employed to reveal the surface morphology of wafers. The AFM is a Digital Instruments Nanoscope III consisted of a piezoelectric scanner with an effective scan range between 0.5 - 13 µm and a silicon nitride cantilever made of silicon nitride. The samples were imaged immediately after cleavage to avoid any contamination and reaction from ambient. The force constant of the cantilever was 0.12 N/m, and there were no apparent tip-induced deformation occurred on the scanning surfaces. CdZnTe is very hydrophobic since the effects of humidity on AFM image were not observed although the humidity level was typically above 50%. Figure 2. shows the schematic presentation of AFM.



Atomic Force Microscope (AFM)

RESULTS AND DISCUSSION

A single crystal of $Cd_{0.8}Zn_{0.2}Te$ was successfully grown and was 3 cm in length with 1.2 cm in diameter. The as-grown crystal was then cut into three sections along growth direction which are at the beginning of growth, middle of growth and

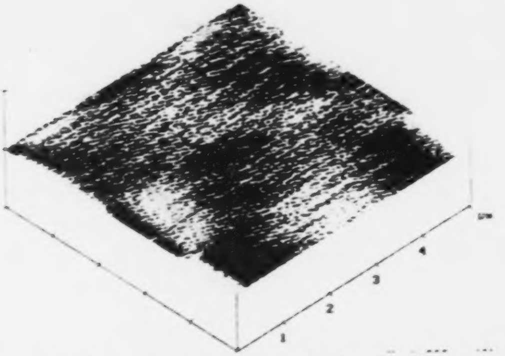

Figure 5. The Surface Morphology of $Cd_{0.8}Zn_{0.2}Te$ Crystal at the End of Growth Process.

end of the growth. For each sample, AFM images were taken on different areas, and only the typical image is shown. The Z range of all AFM images is 30 nm. Figure 3 shows the surface morphology of crystal grew at the beginning stage of growth in 5 × 5 μm area. The surface roughness is 0.3 nm and some precipitates have been observed as small white features on the right edge of Figure 3 with size ranging from nm to µm and 1 - 4 nm in height. Figure 4 and 5 show the surface morphology of $Cd_{0.8}Zn_{0.2}Te$ crystal at the middle and end of growth in 5 × 5 μm area, and the surface roughness are 0.032 and 0.044 nm respectively. No precipitates have been observed on this magnification scale. Similar studies have been performed on CdZnTe crystals grew by seeded physical vapor transport (SPVT) method under various Cd over pressures (Palosz, George, Collins, Chen, Zhang, Hu and Burger, 1996). Good compositional uniformity was achived as indicated by the 0.1 - 0.3 nm surface roughness from AFM images, and precipitates and void with sizes ranging from nano-meter to sub-micron have also been observed in their studies. They contributed this observation to the possible insufficient temperature gradient on the crystal growth interface which resulted in morphological instabilities. In our study, the surface roughness ranging from 0.03 - 0.3 nm and no present of void indicate a good crystal quality in terms structure defect and compositional homogeneity. The precipitates observed in Figure 1 may be contributed to the high vapor pressure of Cd compared to Zn and Te vapor pressures at the beginning stage of crystal growth. This phenomenon has been observed in the studies by Palosz et al. that large size precipitates (> 100 nm) were observed in crystals grew under excess Cd over pressure. After the first stage of crystal growth, the vapor pressures of Cd, Zn and Te might reached equilibrium and stoichiometric conditions in the vapor phase and on the crystal growth interface. Therefore no precipitate have been observed on crystal sections taken from the middle and the end stages of growth.

CONCLUSION

A $Cd_{0.8}Zn_{0.2}Te$ single crystal was successfully grown from physical vapor transport method using 970 °C and 8 mm/day as growth temperature and growth rate respectively. The surface morphology of crystal was revealed by atomic force microscopy along the growth direction. Some precipitates were observed in the crystal during the first stage of growth, and might be caused by the higher Cd vapor pressure. Equilibrium growth conditions have been achieved after the first stage of growth. The results show that the overall quality of the as-grown crystal is superior in terms of structural and compositional uniformity as indicated by the surface roughness and lack of precipitate and void.

James Kakalios

When a mixture of fine sand and crystalline sugar is poured against the closed edge of a quasi-two-dimensional Hele-Shaw cell (two vertical, transparent plates held a short distance apart) the mixture forms alternating stripes of pure sand and pure sugar. The stratification patterns that emerge due to the avalanches are studied with a CCD camera and the resulting digital images are Fourier transformed to produce the structure function of the banding pattern. The segregation can then be quantitatively studied as a function of plate separation and flow rate. We have designed a computer simulation of the process that reproduces the stratification effect based on properties of the granular media.

INTRODUCTION

There has recently been growing interest in the dynamics of granular media such as sand or powders. An interesting property of mixtures of granular particles is their tendency to separate under conditions such as vertical shaking (Olsen and Rippie, 1964) and horizontal rotation (Oyama, 1939; Donald and Roseman, 1962; Bridgwater, 1976; Savage, 1993; Hill and Kakalios, 1994). Another variety of self segregating behavior has been observed by Makse and co-workers (1996), where a binary mixture of sand and sugar will form alternating layers when poured near the closed edge of a "quasi-two-dimensional" Hele-Shaw cell. A theoretical model for this effect has been proposed by deGennes and Boutreux (1996), extending the work of Bouchaud, Cates, Prakash, and Edwards (1994, 1995). Makse and co-workers (1997) have also reproduced the stratification effect with a numerical, computer simulation based on local height differences between rectangular particles. Current models describing avalanche segregation are explicitly for two-dimensional sand piles. The experimental studies are extended to three dimensions by systematically varying the plate width of the Hele-Shaw cell. The segregation process is also studied as a function of the flow rate of arriving particles. Furthermore, a computer simulation based on physical properties of particles has been implemented to reproduce the stratification effect.

EXPERIMENTAL TECHNIQUES

The Hele-Shaw cell (Hele-Shaw, 1898) consists of two vertical Plexiglas sheets 20 cm high and 30 cm long, mounted parallel to each other onto a Plexiglas base. One of the vertical sheets is bolted to the base. The distance between the vertical sheets is controlled by a 20 cm long strip-like spacer that closes one edge of the cell and two small block spacers at the opposite edge. By bolting the vertical plates together with various sized spacers, the plate separation is varied from 3 mm to 24 mm. A 50/50 mixture by mass of sand and sugar is poured near the closed edge of this cell, using a titration bulb with a rotating stopcock to control flow rate. The sand has been dyed blue/black for contrast in the photos without affecting the segregation process. Digital photos of experimental runs are taken with a monochrome CCD camera (Cohu 4910) in conjunction with a Scion LG-3 frame grabber and a Power Macintosh 7100/80. Data image analysis is performed with the public domain program Image from the NIH.

EXPERIMENTAL RESULTS

Figure 1 shows a digital image of the resulting sand pile formed by pouring a 50/50 sand/sugar mixture at 0.78 ± 0.08 gm/sec near the closed edge of the Hele-Shaw cell with a plate separation of 4 ± 0.5 mm. The first feature of note is the "dead-zone" of mixed sand and sugar at the lower right hand corner in figure 1. The size of this zone depends on both the plate separation and flow rate. In addition, the stratification is most apparent in the middle of the sand pile, with single species of sand and sugar collecting at the top and bottom of the pile respectively. Makse and co-workers (1996) also noted this "downhill segregation" with the larger, less dense sugar particles flowing further down the pile. Identical patterns have been observed when the mixture is poured in the center of the cell, indicating that segregation is not an edgewall effect.

Increased Sugar Concentration

Figure 1: Digital image of the resulting sand pile formed by pouring a 50/50 sand/sugar mixture at 0.8 gm/sec near the closed, right edge of the Hele-Shaw cell (not shown) with a plate separation of 4 mm.

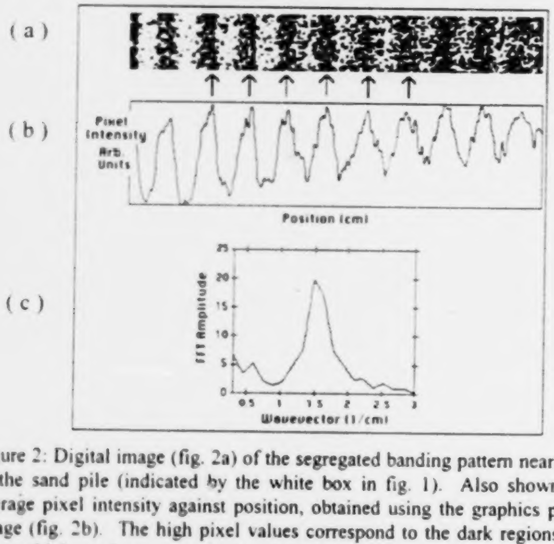

Figure 2: Digital image (fig. 2a) of the segregated banding pattern near the top of the sand pile (indicated by the white box in fig. 1). Also shown is the average pixel intensity against position, obtained using the graphics program Image (fig. 2b). The high pixel values correspond to the dark regions of the image (high sand concentration) and the low pixel values indicate regions of high sugar (white) concentration. This data is then Fourier transformed to yield the structure function of the banding pattern (fig. 2c).

Previous theories on avalanche segregation have not discussed the influence of plate separation on the segregation process. Therefore, a systematic study of varying vertical plate separation in the Hele-Shaw cell has been completed. Two trends are observed as the plate separation is increased at a constant flow rate: the degree of segregation decreases as does the spacing between segregated bands. These trends are quantified through measurement of the structure function. Figure 2a shows a digital image of the banding pattern near the top of the sand pile, as indicated by the white box in figure 1. The program Image can plot the pixel intensity against the horizontal position. Using white sugar and black sand lets us correlate the pixel intensity to the concentration of sand near the transparent vertical plate of the Hele-Shaw cell. The resulting pixel intensity graph (fig. 2b) is fast Fourier transformed to yield the structure function for the banding pattern (fig. 2c).

The location of the peak in the plot of FFT amplitude against wave vector in figure 2c gives the average wavelength of the segregated bands, while the amplitude of the peak provides a quantitative measure of the degree of segregation. Both the degree of segregation and the average wavelength of the bands decrease in a nonlinear manner as the plate separation is increased. The FFT amplitude as a function of plate width is accurately described by either an exponential or power law relationship (fig. 3a and b).

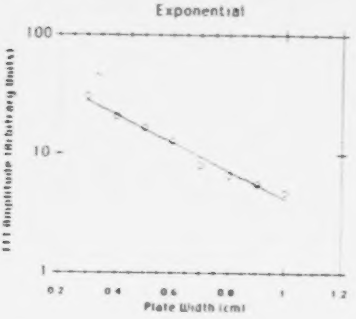

Figure 3a: Log-linear plot of the peak amplitude in the structure function for the avalanche segregation banding pattern against plate separation of the Hele-Shaw cell for a mixture of sand and sugar. The solid line is a fit to the data with an exponential dependence on plate separation.

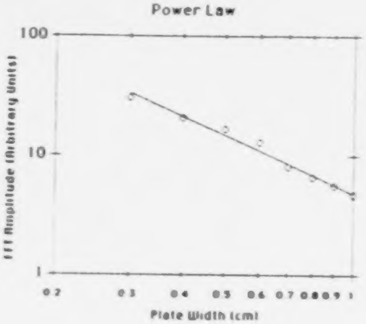

Figure 3b: A Log-log plot of the data in fig. 3a, indicating the equally good power law fit, where the power law exponent is ~ 1.6.

Ideally one would like to extend the horizontal scale for figures 3a and 3b in order to determine which functional form accurately describes the data. However, at smaller plate separations one can not force enough of the granular mixture into the Hele-Shaw cell at a uniform flow rate, while at larger plate separations the segregation effect disappears. Further experiments using alternate granular mixtures, for which the segregation effect persists at larger plate separations, are presently underway and should enable a determination of the functional form of the plate width dependence.

The width of the bands (wavelength) depends on the time interval between avalanches, which, in turn, depends on properties of the granular material (that determine the maximum angle of repose), the plate separation, and the flow rate. For a given plate separation, there is a maximum flow rate at which segregation occurs. For rates above this sharply defined maximum flow rate, a completely mixed sand pile results, due to a continuous flow regime.

A peculiar feature of the experiment that is unaccounted for in current theories is the phenomena of pairing between segregated bands of pure species at plate separations of 5 - 8 mm and flow rates of 0.75 - 1.00 g/s.

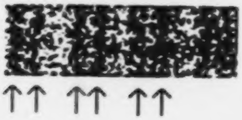

Figure 4: Example of pure species band pairing at a plate width of 6.5 mm and a flow rate of 0.832 g/s.

The observed behavior of the avalanching system described, indicates conditions at which segregation will occur. When plotting the factors governing avalanche segregation (flow rate and plate width) against each other, we find upper and lower nonlinear boundaries at which segregation ceases. This pseudo phase diagram involving plate width and flow rate quantifies the constraints needed in a system to produce segregation in disordered binary mixtures. Work is currently underway toward further understanding of the conditions governing avalanche segregation and completion of the previously mentioned phase diagram.

COMPUTER SIMULATION

Previous numerical simulations of granular media stratification have used a lattice grid of rectangular particles, where each particle must reside in a specific column. Movement of individual particles is determined by the height difference between adjacent columns, with the criteria dependent on the sizes of the moving particle and the stationary particle on which it rests. A physical simulation that incorporates material properties of the granular media, such as size, shape, momentum, and center coordinates has been developed in correlation with the experiment.

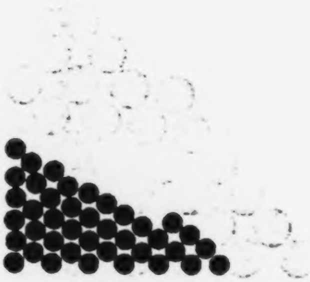

Figure 5a: Overlapping piles of pure species indicate a higher angle of repose for the larger particles, which is a necessary condition for stratification.

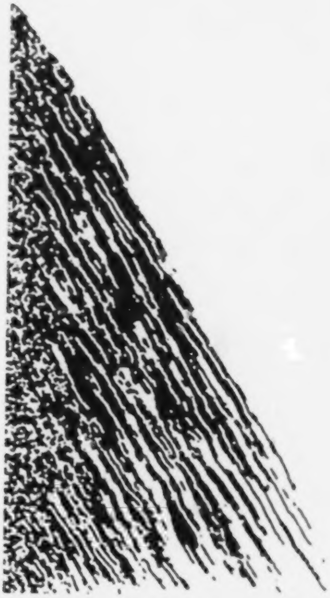

Figure 5b: Resulting stratification pattern from a simulation of 10,000 particles with a 50/50 volume ratio of the large, gray particles to the small black particles.

In the simulation, circular particles arrive near the closed edge of a two-dimensional, "virtual" Hele-Shaw cell with an initial momentum. Each particle bounces according to kinematic equations, losing a fixed percentage of momentum at each collision. When its momentum is below a critical value, its rolls until its momentum approaches zero. During the rolling phase, the particle loses a fixed percentage of its momentum each time it passes a stable position. (A stable position occurs when a particle's horizontal, center of mass coordinate lies between two, simultaneous contact points.) Preliminary results yield a stratification pattern dependent upon a larger angle of repose for the pure species of large particles (fig. 5a). This corresponds to the local height difference criteria that Makse and coworkers used in previous simulations (1997). However, the slope variation is caused by differing initial momentum values for large and small particles. Stratification results when larger particles move down the hill and build a layer up from the bottom, while smaller particles stack up at the top of the pile and eventually avalanche over the large particle band. While these initial results are encouraging, the simulations do not reproduce the sharp nearly periodic segregated layers as in figure 1. Work is continuing in order to refine the simulation algorithm to include the effects of local variations in the critical angle of repose of the pile and improve the match between simulations and experiment.

Paleoclimate analysis from caves in Albania and Portugal, show correlation with known archaeological and climate data in these areas, using MS and VIS measurements. MS data allow determination of warm versus cold climates. The Dry–Wet index, a method combining MS and VIS data for the mineral goethite, can be used to determine variations in rainfall driving soil formation (pedogenesis). MS and VIS methods are applied here to samples from archaeological excavations at Fontéchevade and La Chaise caves, France, and allow estimates of climate during the time of the Neanderthals. Paleoclimate variations are useful in understanding site evolution by correlating MS from samples to the excavations where macro- and micro-faunal data are available. Paleoclimatic sequences are preserved in caves, sheltered from weathering effects associated with exposure. These effects produce, during times of cooler climate, soils outside the cave that have lower MS magnitudes than those produced during warmer climates. Soils, eroded and redeposited in caves undergo limited post–depositional pedogenesis and biological disturbance. Paleoclimatic estimates fro such samples can then be made for all archaeological levels.

BACKGROUND

Fontéchevade Cave is located outside the village of Fontéchevade, in the Charente district of SW France (fig. 1). Two areas are currently being excavated: the main excavation (main coupe), located toward the front of the cave and a secondary "sondage" or test excavation located well in the back of the cave. Both areas have been excavated previously by French workers and are now being re-excavated by a team of French and American workers led by Prof. André Debénath at the University of Perpignan in France and by Dr. Harold Dibble and Dr. Phil Chase at the University of Pennsylvania.

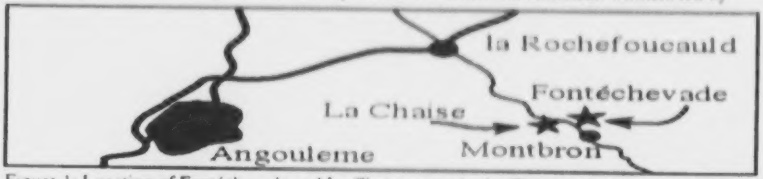

Figure 1: Location of Fontéchevade and La Chaise caves in the Charente district of SW France (not to scale). Fontéchevade and La Chaise caves are about 5 kilometers apart.

Located just a few kilometers from Fontéchevade Cave is the La Chaise Cave excavation (fig. 1). At both Fontéchevade and La Chaise, the caves evolved along a N–S trending system of fractures in a Jurassic limestone that is exposed in the area. La Chaise Cave consists of several rooms including the one, Bourgeois– Delaunay, for which data are reported here.

PREVIOUS WORK

There are many uses of magnetic geophysical data. These include the commonly known methods like magnetic prospecting where magnetometers are used to locate buried objects in environmental exploration and in archaeology as well as locating other unusual zones in the subsurface, such as geological anomalies including faults and other features. Magnetic surveys have been used to locate buried cultural features since the 1950's, but only by a few individuals (Martin et. al., 1991). The recognition and measurement of unusual magnetic anomalies in the subsurface, caused by changes in the concentration, orientation and type of iron oxides, mainly maghemite and magnetite in the soil, is the key to locating buried archaeological sites and features. Other magnetic anomalies are often found associated with storage pits, due to higher humus content, or buried, high–iron–content objects and hearths (Weymouth, 1986).

In archaeology, research in archaeomagnetism is also important, where Earth's magnetic field signature, acquired by objects such as hearths built by ancient peoples, can be used as an important relative dating tool (Ellwood, 1971; Wynn, 1986). Archaeomagnetic samples come mainly from hearths, kilns or associated sediments, but they can also include those materials that accumulated at the site during long periods of slow sediment deposition.

Magnetic susceptibility (MS) is another, but very different type of magnetic measurement. Simply stated, MS is a measure of how susceptible a material is to becoming magnetized when placed in a small magnetic field. All materials exhibit MS, but many iron–containing minerals are very easily magnetized and therefore show a strong MS signature. Quartz or calcite, on the other hand, very common minerals in sediments, show an MS response only when measured using the most sensitive instruments. MS measurements of loess and other sediments have been used recently in paleoclimate studies and as a proxy for the much slower, costly and time–intensive oxygen isotope ($\delta^{18}O$) measurements that are most often used in the analysis of deep–sea sediments (Imbrie et.al, 1984). The alteration of magnetic minerals that occurs with a changing climate allows MS to be effective as a proxy. These changes come about primarily through the process of pedogenesis (soil formation). Recently, MS measurements have been employed in the study of archaeological materials taken from caves in an effort to characterize ancient climates (Ellwood et al., 1997). This work is based on the premise that during pedogenesis, magnetic minerals such as maghemite are formed. When climate is warm, more maghemite is formed than when climate is cold. The soil formed outside of caves is washed into caves, thus filling these caves over time with sediment containing varying amounts of maghemite, depending on the climate at the time of deposition. Living in these caves were ancient people, so that the material artifacts they left behind are buried by the sediments accumulating in the cave. By analyzing the MS of sediments at different levels in the cave, the paleoclimate can be reconstructed for the time during which people were living there. In turn, the effect of climate on these ancient peoples can be studied.

It has also been shown that MS variations can be used to correlate between excavations (Ellwood et al., 1994; 1995; 1997). This is important to archaeologists because they have no easy way of correlating archaeological levels and because the sediment layers containing artifacts are often difficult to interpret. MS profiles show trends and magnitude variations (discussed below) that allow correlation when the trends and magnitudes are similar and the ages of excavations overlap. This report presents preliminary results from the Fontéchevade Cave excavations in the Charente district of SW France. Also included here are MS results from an additional excavation performed several years ago in the cave of La Chaise by Prof. Debénath.

Spectral reflectance (VIS) measurements in the visible light range have been used for the purpose of characterizing the iron mineralogy in sediments and have been shown to be very useful in archaeological studies (Ellwood, et al., 1995). This early work helped delineate paleosols within studied sections as well as helping with intra–site correlation.

METHODS

Sediment samples were collected in 8cc plastic sample boxes along continuous vertical profiles at each site studied. Continuous samples are used to reduce the chance of omission of a stratum from the data set. Each sample was given a sequential number in the profile set and the depth to the sample location was measured. This was accomplished using an electronic surveying device and a grid laid out with an arbitrary zero from which to gather the vertical, horizontal and lateral position of the top and bottom sample in each profile. Individual sample position was then calculated by extrapolation.

MS was determined using a balanced induction coil instrument commonly called a susceptibility bridge. In the susceptibility bridge each sample is exposed to a small magnetic field and a digital readout is recorded. This process is repeated 3 times, the mass of each sample is measured and then these data are fed into a computer and the MS calculated relative to a set of standards. (The bridge at UTA is calibrated to results from the National Bureau of Standards [Schwartzendruber, 1992]). The resulting MS data are then used to estimate the temperature (warm or cold climate) at the time of deposition, higher MS values indicate warmer climate while lower MS means colder climate.

VIS data were determined using the Perkin–Elmer Lambda 6 Spectrophotometer at. This process used a powdered sample, mixed to a thin slurry with deionized water and spread evenly on a standard glass microscope slide. After allowing to dry thoroughly, it was analyzed in the spectrophotometer. The first derivative of the resulting spectral peak at 435nm wavelength was used to estimate the percentage of goethite in each sample. A dry/wet (DW) index was developed for the normalized MS and VIS data sets from the expression:

$$\text{DW Index} = (\text{Norm MS})/(\text{Norm VIS}). \qquad (1)$$

RESULTS AND DISCUSSION

At Fontéchevade Cave the main coupe and sondage are stratigraphically the same at approximately 2m below the main datum. While the MS data trends at this point are similar between the two profiles, the point of overlap was not chosen based on this correlation but on the stratigraphic similarity. Figure 2 shows the profile of the two data sets with the overlapping points. The similarity between the two is evident at depths of 2m and greater. Given the horizontal separation of the two profiles, ~14m, and the high agreement between the MS data

BEST COPY AVAILABLE

sets, a strong correlation can be confirmed.

MS data for Fontéchevade Cave indicate that the deposition started during glacial times (low MS magnitudes) while increasing MS values at the site indicate that climate was warming as time progressed. Within the major cycle (general trend) indicated in the data set there are many more subtle cycles that allow for correlation to other sites as well as estimates of short–term climatic variations. These cycles indicate brief periods of warming and cooling that quickly dissipate.

Three areas were sampled at La Chaise Cave and these are located within 15m of each other. Stratigraphically LC–1 and LC–2 are similar at >1.5m depth (fig. 3). As with Fontéchevade Cave, the correlation of the MS data between units is very good although the point of overlap at

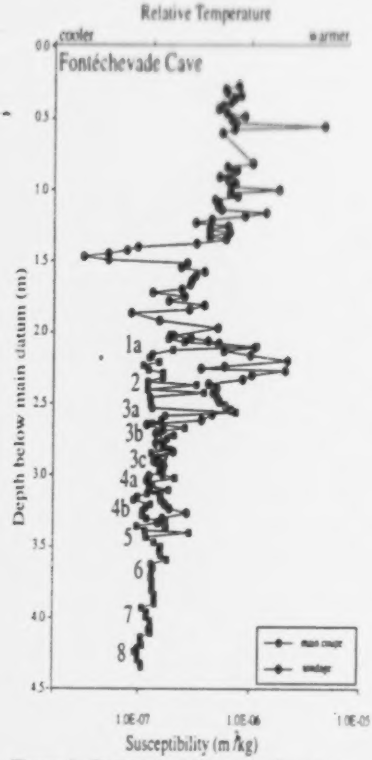

Figure 2: Composite MS profile from two excavation units within Fontéchevade Cave. There is about 14 meters separation between the main coupe and the sondage. The archaeological levels shown are for the main coupe.

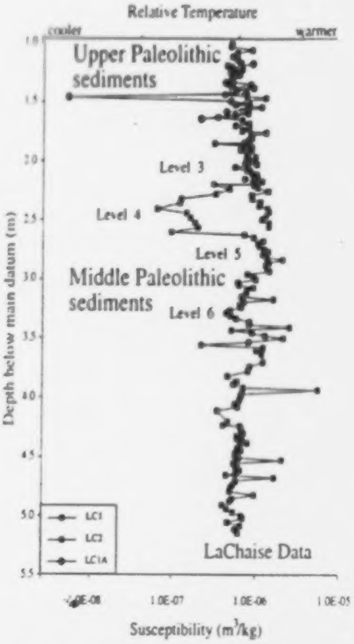

Figure 3: A composite MS profile from three excavation units, LC–1, LC–1A, LC–2, within La Chaise Cave. The single low MS value near 1.5 meters depth represents a limestone layer and is an indicator of an unconformity or missing sediments in the record. Sediments below are Middle Paleolithic while the sediments above are much younger Upper Paleolithic. The archaeological levels from LC–2 are given.

La Chaise Cave was chosen based on the MS data and not on the stratigraphy. Figure 3 shows the MS data for two areas, LC–1 and LC–2. There is a set of anomalous MS values associated with samples that were collected from loose soils filling voids between limestone blocks that fell as a single break–down event. This zone is represented as archaeological Level 4 and when the data from this level are removed, a clear correlation between the two profiles is apparent. Also plotted in Figure 3 is an additional profile from the back of the cave, LC-1A. Combining multiple profiles in this way results in a single composite profile that represents all the MS variations recovered from within the cave. These data can then be interpreted in terms of climatic variations or be used to correlate to other archaeological sites in the area.

At Fontéchevade Cave the composite MS data show a general warming trend in overall climate with times of greatest warmth evident in the shallowest sediments. There are several short–term climate variations within the overall warming trend and one period that is indicative of much colder climate (fig. 2). While the large–scale climate trend can be attributed to a Milankovitch climate cycle, the minor fluctuations may be the result of local short–term climate anomalies or they may be Neo–glacial cycles.

BEST COPY AVAILABLE

The La Chaise site has MS data showing the final stages of a warming trend giving way to the beginning of a cooling trend (fig. 3). This change marks the beginning of the next glacial cycle and has been dated to ca. 120,000 years (Blackwell et al., 1983). Smaller fluctuations are again present representing minor changes in the overall climate. These minor changes have been used to correlate between the Fontéchevade and La Chaise composite profiles (fig. 4). Note the excellent agreement between the lower portions of the La Chaise MS data set and the upper portions of the Fontéchevade data set. While magnitudes and trends are similar, in particular there are three short–term climate peaks that are represented in both composites. The time separating these peaks, as well as the relative magnitudes are essentially identical between the two caves. The composite profile in Figure 4 is the result of inter–site correlation.

Examination of the MS composite profile for Fontéchevade and La Chaise caves (fig. 4) shows a cold beginning (glacial time) with warming through most of the sequence. Then late in the history represented in these sediments, climate reached a maximum (interglacial time) and began to cool once again. This long–term trend is punctuated with 3 very short–term warming events as well as one longer, but short–term very cold event that may have been similar in magnitude to the Younger Dryas, Neo–glacial cycle, ca. 12,500 to 11,500 B.P. (O'Brien et al. 1995).

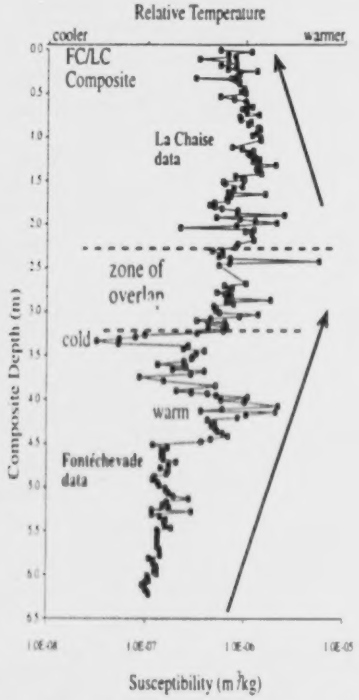

Figure 4: Composite MS profile for Fontéchevade and La Chaise caves with interpretations of warm/cool climatic conditions. The zone of overlap represents the area of the correlation between the two sites.

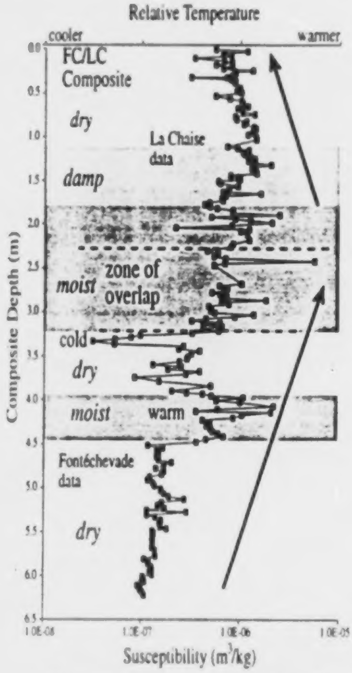

Figure 5: The composite MS profile for Fontéchevade and La Chaise caves (fig. 4) with the DW index data included indicating wet/dry climatic conditions. Overall wet/dry is shown in shaded bars is in agreement with the general trends seen in figure 4.

Using the VIS data for Fontéchevade and La Chaise caves to determine the D/W index, wet versus dry climatic periods were identified. These periods, in conjunction with the MS data give an estimate of total climate. Most of the sediment recovered from the cold climate represented at Fontéchevade Cave indicates relatively dry times. As the interglacial was approached, however (upper part of Fontéchevade and into La Chaise sediments), climate became more moist. Then, as climate once again began to cool, drier conditions reappeared (fig. 5).

CONCLUSIONS

Research from Upper Paleolithic caves elsewhere in Europe has demonstrated that MS data can yield estimates of paleoclimate and can be used to correlate between archaeological excavations if the excavations overlap in time. These earlier studies demonstrate that higher MS values indicate times of warmer climate, while lower MS magnitudes represent times of cooler climate.

Research from the middle Paleolithic caves at Fontéchevade and La Chaise in the Charente district of SW France demonstrates that MS data allow both intra– and inter–site correlation of these caves. Using this result it was then possible to develop a composite profile, using MS data, that covers the time of deposition represented by sediments deposited in the cave. This composite profile proxies for the climate in the region at the time these sediments were deposited. A preliminary paleoclimate curve for the middle Paleolithic is presented and represents deposition starting during a glacial period, extending into interglacial time, and finally beginning to return to glacial climates.

It is clear from these results that use of these methods at multiple sites can provide links to otherwise seemingly unrelated sites. This is useful in gathering the broad spectrum picture of the region and the associated climate. The sites at Fontéchevade and La Chaise, while in close proximity to each other, show little archaeological evidence to link them chronologically. Use of MS shows that the two sites to have an overlapping history. DW index data, developed from VIS measurements in these caves show that moisture changed very slightly during deposition of these sediments, with higher moisture present during warmer climates.

Caves can provide ideal environments for sediment deposition that are unaffected by in–situ pedogenesis, and from such sediments paleoclimatic trends can be extracted. Because paleoclimate analyses of this type are performed on the entire data set from which archaeological materials are extracted, we believe that MS-VIS data provide a unique opportunity to evaluate the effect of climate on the behavior of ancient peoples.

ACKNOWLEDGEMENTS

Funding for the La Chaise–Fontéchevade project has been provided by the NSF, University of Pennsylvania, the College of Science and Department of Geology at the University of Texas at Arlington, and the UTA Ronald E. McNair Scholars Program. Diamond film coatings have been grown on a Titanium (Ti) alloy using a microwave plasma chemical vapor deposition (MPCVD) technique. Such films were found to consistently detach from the substrate during the cooling period. This detachment is attributed to the large difference in thermal expansion coefficient between the diamond film and the metal substrate. In an effort to minimize these thermal effects, diamond films were grown on Ti-alloy at relatively low substrate temperatures. Two 10 mm diameter Ti-alloy disks were left in the MPCVD chamber for six hours with a 1% methane concentration. Temperatures across the face of these disks ranged from 700-750 °C for the first disk and from 650-700 °C for the second disk. Although film quality remained high, as determined from micro-Raman spectroscopy, the films still exhibited significant detachment. Further attempts to lower the temperature required an elevation to a 3% methane concentration. Diamond was grown on a third Ti-alloy disk at a temperature range of 600-675 °C. This sample exhibited better film adherence, but there was still significant detachment.

INTRODUCTION

Diamond has many properties that make it unique and useful in technology. It is the hardest material known to man, an electric insulator, and a thermal conductor (Martin, 1992). Diamond also has a low thermal expansion coefficient and from the infrared to the ultraviolet it is optically transparent (Ashfold et al., 1994). These qualities make growing diamond in laboratories advantageous to those in industry.

It has been possible to grow synthetic diamond since 1953. In recent years, however, diamond has been able to be grown as films at low pressures relatively cheaply. There are many uses for synthetic diamonds in the fields of optics and electronics (Field, 1991). Since the advent of low pressure diamond growth, synthetic diamonds have found uses as abrasives, coatings for cutting tools, as well as heat sinks (Ashfold et al., 1994).

An important area of research in diamond film growth is the study of growth on metals. A large problem that appears in this area is the ill-adhesion of the diamond to the metal. The large difference in thermal expansion coefficients causes residual stress at the film/sample interface. This stress can cause delamination of the film (Perry et al., 1993).

The method of diamond film growth used in this study was Microwave-Plasma-Chemical-Vapor-Deposition (MPCVD), and the gases used were hydrogen and methane. The film growth rate in this technique is a complicated function depending on pressure, temperature, methane concentration, and sample geometry. Ti-6Al-4V (Ti-alloy) was the metal used in this study. It is used in the aerospace industry and also in dental and medical implant applications (Perry et al., 1993). To prevent delamination, diamond was deposited on Ti-alloy at relatively low substrate temperatures.

EXPERIMENT

Diamond film was grown on three 10 mm diameter Ti-alloy samples. The samples were separately placed in the MPCVD system as shown in Figure 1. Deposition occurred at a pressure of 90 Torr, and each sample remained in the system for 6 hours. The samples were prepared for deposition by being polished with a polishing wheel and 1 micron alumina. The samples were then placed in a beaker with methanol and diamond powder and were agitated in an ultrasonic cleaner for 35 to 40 minutes to enhance diamond nucleation.

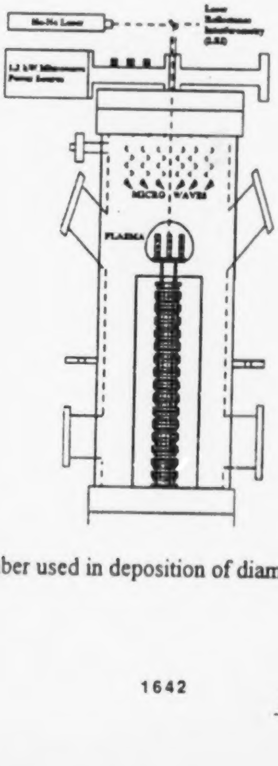

Figure 1: MPCVD chamber used in deposition of diamond films

The samples were placed in the MPCVD system and pumped down to a pressure of about 0.1 Torr. The sample was left in the chamber over night to stabilize. In the MPCVD system, microwaves from a 1.2 kW microwave power supply and hydrogen were used to form a plasma above the substrate. When the plasma appeared to be stable, the pressure and power were slowly raised until the appropriate values of each were achieved. The methane was then turned on and deposition began.

Each sample was watched closely during the 6 hours of diamond deposition, and the temperature was checked often. During the course of the 6 hours the temperature of each sample was seen to increase. It was also noted that although the plasma did cover the entire sample, the plasma sphere was leaning to one side of the sample. This may have been because the chamber is not symmetric. This plasma shift caused a non-uniform temperature across the substrate. The temperature on the side of the sample where the plasma was leaning was, at times, almost 100 degrees higher than the temperature in the middle of the substrate.

The differences in each run were in the temperature of diamond deposition and the methane concentration. The specific conditions for each of the three samples can be seen in Table 1. The temperatures reported are those that were measured in the middle of the substrate over the course of the 6 hour deposition period.

Table 1: Temperature, Power, and Methane Concentration used in deposition of alloy samples

	Temperature (°C)	Power (W)	Methane Concentration
Sample 1	700-750	605	1%
Sample 2	650-700	421	1%
Sample 3	600-675	430	3%

After 6 hours had elapsed, the methane was turned off. The sample was then left in the hydrogen plasma for about 5 minutes. After this the power was turned down slowly over 30 minutes in hopes that a slower temperature change would prevent the diamond film from separating from the Ti-alloy. When the plasma disappeared, the hydrogen and microwave power supply were turned off and the chamber was backfilled with argon.

After deposition, the diamond quality was tested using micro-Raman methods. The spectra was taken using the 514.5 nm line of an argon laser with an output power of around 100 mW. Because crystalline diamond has a sharp Raman peak at 1332 cm^{-1} it is easy to recognize (Knight and White, 1989). The spectra were taken for 60 seconds. The microscope used gave 100x magnification so many points on the sample could be examined.

As previously mentioned, a concern with Ti-alloy samples is that the diamond will not stay adhered to the sample. On Sample 1 diamond pieces were seen to pop off of the substrate as the power was being turned down. This delamination is typical and is shown in Figure 2. The dark spots in the figure are diamond deposits and the lighter spots are the Ti-alloy sample. Despite delamination, the micro-Raman results showed good diamond quality on Sample 1. In addition to the removed diamond pieces, the diamond remaining on the sample was not well adhered and could easily be removed using only finger pressure.

Sample 2 was tested at a lower temperature in an attempt to avoid delamination. The plasma was not uniform and the diamond completely came off on the side of the sample that was at a higher temperature. The diamond on the remaining side of the sample did stay adhered. It also had a high diamond quality as shown by micro-Raman spectroscopy.

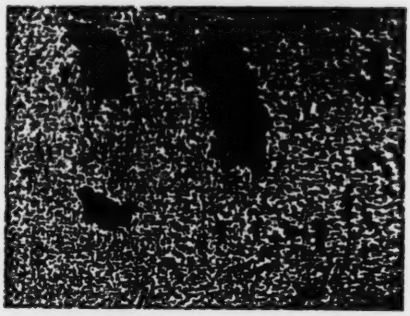

Figure 2: Photomicrograph of Ti-alloy surface after diamond deposition. Image width is 5mm.

Because the power used on Sample 2 was so low, a lower temperature at the same pressure would have been difficult to achieve. Instead, Sample 3 was put in the MPCVD chamber at a temperature close to that of Sample 2. It, however, had a higher methane concentration (3%). The visual results of Sample 3 were close to those of Sample 2 with total delamination on the high temperature side of the sample and diamond on the other parts. The micro-Raman spectra of Sample 3, however, did not show as high of a diamond quality as that found on the previous two samples. A typical micro-Raman graph is shown in Figure 3. The spike at 1332 cm^{-1} on the sloped background is the diamond peak. The broad peak at 1550 cm^{-1} is indicative of an amorphous diamond-like phase coexisting with the diamond crystal.

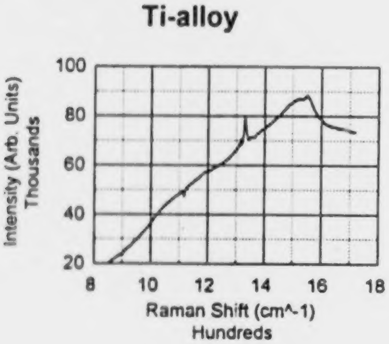

Figure 3: Raman spectrum of diamond coated Ti-alloy taken by 514.5 nm laser

CONCLUSIONS

The experiment resulted in fairly high quality diamond deposits on the Ti-alloy. Despite lower deposition temperatures the stress caused by the difference in thermal expansion coefficients of the diamond and the Ti-alloy was great enough that the diamond did not stay well adhered to the sample. The present MPCVD chamber does not enable a uniform temperature across the sample so complete diamond coverage and adhesion is not easily achieved. The temperature cannot easily be lowered because of the amount of power required to form a stable plasma. Perhaps a layer between the diamond and Ti-alloy is required. The substance making this layer should have a thermal coefficient closer to that of diamond than Ti-alloy has. Research in this area continues, and hopes are high that a method for adequately coating Ti-alloy will soon be found.

Lead iodide source material has been purified using zone-refining process. The zone-refined ingot shows a darker region in the last-to-freeze zone compared to middle and first-to-freeze zone indicating the accumulation of impurities at the last-to-freeze region. A single crystal of lead iodide was grown by the Bridgman method using the middle region of zone-refined ingot as source material. The as-grown crystal shows a bright yellow color revealing the high purity and stoichiometry. Low temperature Photoluminescence technique has been employed to investigate the defect, composition and impurity distribution of as-grown crystal as well as regions along zone-refined ingot. The results shows that purest material can be obtained from the middle section of zone-refined ingot. The as-grown PbI_2 reveal a improved crystalline structure compared to the starting material.

INTRODUCTION

Lead Iodide, PbI_2, was first introduced in 1971 (Roth and Willing, 1971) as potential material as a radiation detector with high efficiency for gamma ray. The wide bandgap of PbI_2, 2.55 eV, along with its high resistivity, 10^8 - 10^9, promise the room temperature operation and low background noise. The high atomic number (Pb = 82, I = 53) and high density (6.2 g/cm3) of PbI_2 also provide a high stopping power for radiation. The structure of lead iodide consists of molecular layers of Pb-I-Pb where the Pb ions are octaherally coordinated (Palosz, 1983). The bonding between layers is of the type of weak van der Waals forces. The weak bonding makes PbI_2 easy to cleave between layers, and is also been categorized as layer compound semiconductor. Various polytypic phases exist in lead iodide solid solution and have been studied extensively (Palosz, 1983, Rao and Srivastava, 1978, Chaudhary and Trigunayat, 1983). It has been established that the high purity and stoichiometry is the 2H phase (Rao and Strivastava, 1978; Chand and Trigunayat, 1977) with a melting temperature of 408 °C. Among layer compound semiconductor, mercury iodide (HgI_2), has similar optical and electrical properties to lead iodide, and has been extensively for its use as room temperature radiation detector. Currently HgI_2 has been implanted in industry and commercial application. Because of the solid phase transition between the orthorhombic and tetragonal phases at 130 °C, detector grade HgI_2 can only be grown from vapor phase which limits the growth rate compared to PbI_2. The lack of any solid phase transition in PbI_2 solid solution up to its meting temperature allows single crystal of PbI_2 to be grow from melt phase (Bridgman method).

Impurities incorporated from source material during crystal growth is a common problem exists and as a consequent result of decreasing the structural, optical and electrical properties of as-grown crystals. Therefore the purification process employed to decrease the impurity concentration in source material is vital to grow high quality single crystal. Among all the purification process, the zone-refining process has been developed for purification of source materials since 1951 (Pfann, 1951). This process has become one of the important technique to produce large quantity of elemental and compound semiconductors. Zone-refining process has been successfully employed to purify HgI_2 recently (Chen, Salary, Burger, Soria, Antolak, James, 1996), and the results show that the impurities with distribution coefficient less than 1, $k < 1$ such as Ag, Cu, Cr, Fe, Mg, Ca, Zn and Al, were accumulated at one end of zone-refined ingot leaving the rest of the material with high purity. Therefore zone-refining process has been employed in

BEST COPY AVAILABLE

this study to purify the PbI_2 source materials to decrease the impurity level for crystal growth. The crystal growth method used in this study is Bridgman method which is a melt growth method. The source materials were enclosed in a pre-cleaned, evacuated and sealed quartz ampoule and placed in a furnace. The materials were first completely melt at a temperature which higher than the melting temperature. Then the ampoule was subjected through a temperature gradient with a temperature lower than its melting temperature and the molten source materials solidified into single crystal. The material characterization technique employed in this study is low temperature Photoluminescence (PL). The results from this spectroscopic technique is to reveal information of quality (defect and impurity), stoichiometry and structure (vacancy, Interstitial) of as-grown crystal and zone-refining ingot. The objectives of this research are to purify the PbI_2 source materials, crystal growth by Bridgman method and investigation of effectness of zone-refining process and quality of as-grown crystal by low temperature Photoluminescence. The final results will be analyzed and correlations will be made to optimize the purification and crystal growth conditions.

EXPERIMENTAL

The PbI_2 source materials are purchased from Alfa, Co., with 4N (99.99%) purity. The ampoule was made from high purity quartz tubing and pre-cleaned by two steps. First the ampoule were soaked in a aqua regia solution (25 Nitric acid + 75 % Hydrochloric acid) and then rinsed with distilled water to clean possible contamination on the surfaces of ampoule. Second step was to baked out ampoule at 500 °C under vacuum (~ 10^{6} Torr) to drive out any residual gases inside quartz wall. A zone-refiner has been constructed and employed to purify the source materials. The heaters traveled from right to left with a speed of 8.5 cm/hour and a temperature of 500 °C. The heaters only melt part of the PbI_2 materials but all other materials along ampoule are still in solid form. After the heater reached the left end of the ampoule, they will traveled back to the right end of the ampoule with a much faster speed which did not melt materials again in reverse direction. Therefore for those impurities with distribution coefficient, k, less than 1, they were swept (in the molten zone) from right (first-to-freeze) to the left size (last-to-freeze) during each circle. The distribution coefficient is defined as k = (solubility in solid /solubility in liquid). The experimental arrangement of Bridgman crystal growth system and the as grown PbI_2 crystal are shown in Figure 1. The starting material for crystal growth was taken from the middle section of zone-refined ingot. These material was then loaded into growth ampoule and sealed under 10^{-6} Torr vacuum. The growth ampoule was then inserted in crystal growth furnace, shown in figure 1, at 420 °C temperature to melt the starting material. The furnace was then translated upward at a speed of 10 mm/day leading the growth ampoule through a temperature gradient which has a temperature zone lower than the melting temperature of PbI_2 (408 °C). Figure 2 show the schematic experimental arrangement for Photoluminescence (PL) measurement. The samples were cooled down to about 10K using an APD Cryogenics Inc. system equipped with a dual HC-4 MK1 helium compressors. An ILT 5500A air-cooled argon laser was employed as excitation source and the wavelength of the laser line is 514.5 nm. A cylindrical lens was used to focus the

After each measurement, the emission lines from a mercury lamp were used for calibration purposes. The photoluminescence spectra were recorded and analyzed by a personal computer using the SPEX DM3000 program mode.

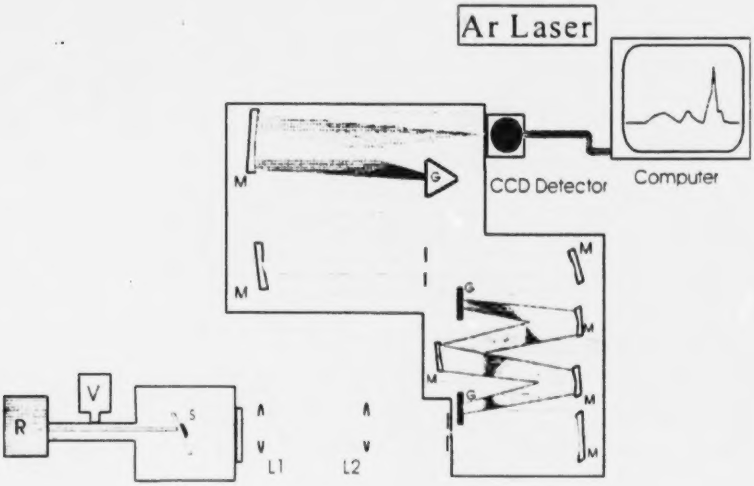

Figure 2 Experimental Apparatus of Low Temperature Photoluminescence

RESULTS AND DISCUSSION

The zone-refined ingot show a darkest color in the last-to-freeze zone and a slightly dark yellow color in the first-to-freeze zone. The material at middle of the zone-refined ingot reveal a bright yellow color. These results from visual inspection show that most of impurities with *k*⟨1 accumulated in the last-to-freeze region, and some other impurities with *k*⟩1 may accumulated in the first-to-freeze section by the reverse zone-refining effect leaving the purest material in the middle region. The as-grown crystal show a more bright and shiny yellow color compared to the starting material because of its better crystallinity. Figure 3 show the PL spectra of as-grown PbI_2 single crystal, first-to-freeze, middle and last-to-freeze sections along zone-refined ingot. The peaks in the region of 2.3 - 2.4 eV are the characteristic emissions of PbI_2, and can serve as a qualitative measurement of the quality of PbI_2 in terms of purity and crystallinity. The last-to-freeze material show no characteristic emission , while the materials from first-to-freeze and middle sections reveals the characteristic peaks centered around 2.36 eV with increasing PL intensity. These results indicates that the last-to-freeze section accumulated more impurity with

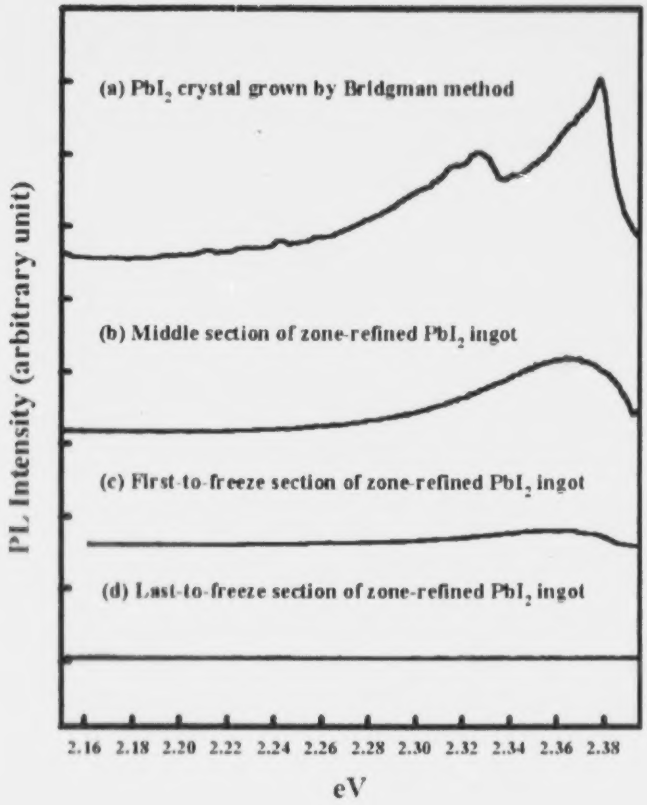

Figure 3. PL spectra of as-grown PbI$_2$ single crystal and materials from zone refined ingot

$k<1$ than other region along zone-refined ingot. Figure 3 also show that the intensity of the first-to-freeze material is much lower than the intensity of the middle material. This result indicate that the first-to-freeze region also contained some level of impurity ($k>1$) leaving the middle region to be the purest material. The well-resolved doublet peaks at 2.33 and 2.37 eV from as-grown crystal shows the superior crystallinity compared to the material from the middle region of zone-refined ingot which the PL spectrum can not resolve the doublet due to its polycrystalline structure. The results from PL measurements are in agreement with the results from visual inspection.

CONCLUSION

Zone-refining process has been applied to purify lead iodide starting material. Bright yellow high purity, compared to original material, PbI$_2$ material was obtained from zone-refined ingot for single crystal growth by Bridgman method. A single crystal of PbI$_2$ was successfully grown. The results from low temperature photoluminescence measurements revealed that the last-to-freeze zone did accumulated more impurities. The first-to-freeze zone also contained some other impurities leaving the material at the middle zone to be the purest along zone-refined ingot. The as-grown crystal also show a improved and superior crystalline structure compared to the purest material from zone-refining process

Recalibration of the Wilson-Bappu Effect Using the Singlely Ionized Magnesium k and h Lines

Frederick Scoville

Physics Deparment
University of Nebraska at Kearney
Bruner Hall of Science
Kearney, NE 68849

Faculty Advisor:

Jose Mena-Werth

This study presents a new calibration of the Wilson-Bappu effect using the data from a survey of the the Mg II h and k lines (centered at about 280 nm) taken from the archives of the International Ultraviolet Explorer satellite. It was found that only well exposed spectra were allowed to observe the full base width of the Mg II h and k lines. An additional selection criterion is the elimination of spectra with missing or contaminated data bins. This study derives a calibration using a sample of approximately 70 stars. Absolute magnitudes are derived either from angular parallaxes greater than 0.040" or from their Ca II K line width measurements and application of the Wilson-Bappu effect.

BACKGROUND

This study incorporates the Wilson-Bappu effect for singlely ionized magnesium (Weiler and Oegerle, 1979; Mena-Werth, 1990). The Wilson-Bappu effect was first documented in 1957 using singlely ionzied calcium (Ca II). This effect relates the absolute magnitude of a star, M_V, with the corresponding width of the Ca II K line emission from the star's chromosphere (Wilson and Bappu, 1957). It was shown that the absolute magnitude of a star correlates linearly in response to the logarithm (base 10) of the full line base width of the Ca II K line . A similar approach has been developed with the chromospheric Mg II k and h lines. These lines are centered in the ultraviolet portion of the spectrum at 279.55 nanometers and 280.27 nanometers, respectively. The reasons for using the Mg k an h II lines include a greater abundance of the element as compared to calcium within most stars, their corresponding greater emission strength, and the availability of measuring devices for the lines Mg II k and h lines.

The data for the Mg II k and h lines comes from International Ultraviolet Explorer (IUE) satellite. This satellite was a joint American and European venture deployed by NASA in 1978 to measure the ultraviolet portion of the spectrum. The reason for its deployment is because most of the ultraviolet portion of the spectrum is cut off by the atmosphere. Thus, direct ground-based observations of stellar UV radiation is not possible. The IUE uses an 18-inch reflecting telescope that is used in conjunction with other equipment to detect ultraviolet radiation, which is in turn connected to a television camera (Heavens, 1991). The data is then sent and stored into archives at NASA's Goddard Space Flight Center, and this data can be accessed remotely as needed.

DATA

The data from the IUE was reported in a flux versus wavelength format. The emissions for the Mg II k and h line widths, at the base, were then measured using the standard IUE data reduction package at NASA's Goddard Space Flight Center. The working data for this study came in three stages. A graph of the region containing both the k and h lines was one stage and isolation of the k and h lines, reported separately, were the other two stages. The star identification and the line width were taken from this set-up. Other relevant information, such as apparent magnitude and spectral class, were then taken from the Bright Star Catalogue (BSC).

When working with the Wilson-Bappu effect, the width of the k and h lines is reported in a (km/s) format, which can be obtained by the following formula:

(delta wavelength/lab wavelength)=((width in km/s)/c), (1)

where the lab wavelength is the same as the centered wavelength reported previously, delta wavelengths are measured across the base of the emission for the k and h lines, and c is the speed of light (Bohm-Vitense, 1989).

The absolute magnitude of the corresponding star was then determined in one or more the the following ways: (1) by the trigonometric parallax as reported by the BSC, (2) by the trigonometric parallax as reported by the General Catalogue of Trigonometric Parallaxes (GCTSP) (van Altena, et al., 1991), (3) from Wilson, 1976 and the absolute magnitude values as determined by using Ca II K line.

When using parallax, the absolute magnitude of the star can be formulated as follows:

$$M_V = m_V + 5 + 5 \log_{10} (pi), \qquad (2)$$

where m_V is the apparent magnitude and pi is the parallax in arc seconds (Bohm-Vitense, 1989).

The absolute magnitudes as reported by (Wilson, 1957) have a dependence upon the Hyades modulus. This modulus was found to be 3.40 based upon the 156 light-year distance as reported in by Torres, et al., (1997) as compared to the 3.03 modulus as used by Wilson, 1976. The linear correction for the absolute magnitudes was then corrected as proposed by Wilson (Wilson, 1976).

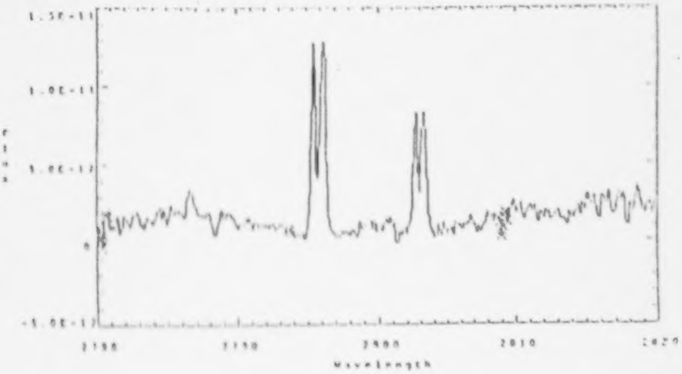

Figure 1: Data from HD161096 as reported from the IUE satellite archives. The k line is centered at 279.55 nm while the h line is centered at 280.27 nm.

ANALYSIS

The first step in the analysis involved a determination of usable data. The factors for selection of the k and h line widths for a star were determined by the following criteria: (1) an absolute magnitude either reported by another study (Wilson, 1976) and/or having a parallax of more than 0.0400 arc seconds, (2) a significant signal-to-noise ratio, and (3) k and h lines devoid or nearly devoid of Reseaux marks, or places where data was lost during the exposure. By using these criteria, the study was able to involve approximately 70 stars into the selection for each section of comparison.

Once the stars and data were determined fit for use, the width of the k and h lines and absolute magnitudes for a selected star were determined as stated previously. Then a comparison of the absolute magnitude versus the logarithm (base 10) of the width of the lines (in km/s) was constructed. The k and h lines were handled as separate and independent entities. This allowed for the two emissions to obtain separate and independent relationship with respect to absolute magnitude. This was a slightly different approach that in previous studies with Mg II which found a relationship using the k line only (Weiler and Oegerle, 1979; Mena-Werth, 1990).

The possible avenues for comparison involved the lines widths in correlation with the absolute magnitude sources as given earlier. Two more comparisons were made using combined sources of Wilson and the parallax sources. These final sections allowed for a large range of stars to be included into a comparison that was not achievable by the other three sections separately.

Each exposure was handled as a separate data point in comparison to the absolute magnitude of the star. In other words, no attempts to average the line widths for multiple exposures of the same star were taken. Some stars in this study only contributed one exposure while some stars had contributions of three or more exposures.

After the scatter plots were constructed, then a linear fit of the following form was performed:

$$M_V = A + B \log_{10} W_{((k \text{ or } h)\ \mathrm{km/s})}, \qquad (3)$$

where A and B are constant coefficients determined by a least squares fitting of the data. The following table gives the results of the forementioned sources for absolute magnitude versus the logarithm of the k and h line widths.

Table 1: Results of various absolute magnitude sources versus associated line widths.

Source of M_V	Equation	r_p	Data pts.
BSC	$27.554 - 11.096 \log W_k$ km/s	0.75713	120
BSC	$21.844 - 8.5946 \log W_h$ km/s	0.6949	120
GCTSP	$28.006 - 11.333 \log W_k$ km/s	0.7433	110
GCTSP	$22.772 - 9.0459 \log W_h$ km/s	0.6946	110
Wilson, 1976	$33.080 - 14.307 \log W_k$ km/s	0.85117	74
Wilson, 1976	$27.894 - 12.289 \log W_h$ km/s	0.76988	74
BSC and Wilson, 1976	$36.997 - 15.727 \log W_k$ km/s	0.89702	194
BSC and Wilson, 1976	$31.691 - 13.591 \log W_h$ km/s	0.85213	194
GCTSP and Wilson, 1976	$37.053 - 15.781 \log W_k$ km/s	0.89798	184
GCTSP and Wilson, 1976	$32.331 - 13.902 \log W_h$ km/s	0.85764	184

The best recalibration of this study was the result for the Mg II k line obtained by combining Wilson's 1976 data with combined with the absolute magnitudes as determined by the parallaxes reported by the GCTSP.

$$M_V = 37.053 - 15.781 \log W_k \ \mathrm{km/s} \qquad (4)$$

This result then compares favorably with the results as determined by Weiler and Oegerle (1979). Their results using the Mg II k line were as follows:

$$M_V = 34.93 - 15.15 \log W_k \ \mathrm{km/s} \qquad (5)$$

with a linear correlation coefficient of 0.91.

The error analysis was handled in a similar manner as with Weiler and Oegerle (1979). Stars with a parallax of 0.100" or greater were taken and the values of absolute magnitude were compared as obtained by parallax and by our main relation for k line width used to determine M_V. We then looked at the standard deviation to obtain a sense of range for M_V with errors. By using this method, we were able to incorporate 21 stars and forty-five data points. The error amount was then found to be 1.16 magnitudes.

DISCUSSION

The relations obtained by using the Mg II k and h lines and various sources for absolute magnitude follow a similar pattern as first one found

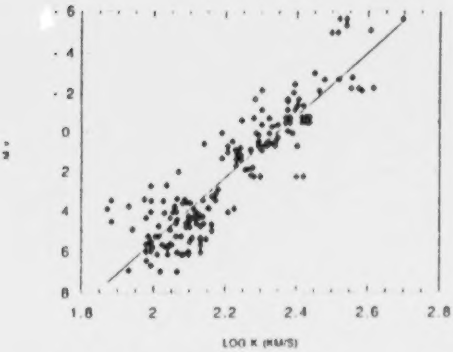

Figure 2: Correlation of the absolute magnitudes from GCTSP and Wilson, 1976 versus logarithm of the k line width with a least squares linear fit.

by Wilson and Bappu in 1957 and others thereafter. Both the k and h line widths correspond well with changing intrinsic brightness. Values for these relations are close to those determined in other studies, of which both Ca II and Mg II are used (Wilson, 1976; Weiler and Oegerle, 1978; Mena-Werth, (1990). The relations displayed a behavior that was intermediate for the absolute magnitudes, for a given line width, than in previous findings. While this study's values would exceed those as found by Weiler and Oegerle (1979), the would be exceeded by the values as determined by Wilson (1976) and Mena-Werth (1990).

The error range is slightly larger than one would like to see with this type of process. Having a range of greater than one magnitude could change things significantly in some situations. However, the error range is still small enough that the process is not rendered meaningless. Such as its use as a guide to checking other techniques to determine absolute magnitudes.

When comparing the absolute magnitudes as determined between the k and h lines, the k line generally more highly correlated. The Wilson-Bappu effect followed the h line, but with less of a correlation than that established by the k line on the same group of stars and M_V. This relation of lesser correlated h line widths with absolute magnitudes as compared to k line widths permeated all subsections of this study. The main reason for this distinction was the way the UV radiation is detected by IUE. The Mg II h line is near the edge of the viewing camera. Thus, distortions and errors are introduced into the h line width. Therefore, when possible, it would be advisable to use the k line width when incorporating the Wilson-Bappu effect with Mg II.

For certain stars, multiple exposures were used use in this study. When dealing with some of these multiple exposures, a spread in the k and/or h line widths existed. For some stars, such as HD222107, a possible relation of line width with exposure time may be supported as found by Mena-Werth (Mena-Werth, 1990). With other stars, the spread may only develop as a result of more noise in the signal than an another exposure.

CONCLUSION

This study's purpose was recalibrate the Wilson-Bappu effect by using various sources of absolute magnitude in correspondence with Mg II k and h line widths as determined by the International Ultraviolet Explorer satellite. The study was able to include several more stars into the study than in previous surveys, especially in the main sequence portion. It was found that the k line width correlation gave a better result than the same technique used with the h line width of Mg II. Also, the relations calculated in this paper were in good agreement with those found by other researchers, most notably Weiler and Oegerle, 1979.

ACKNOWLEDGEMENTS

Thanks goes out to Dr. Jose Mena-Werth for the guidance and insight needed for the completion of this study. Notice is given to the University of Nebraska at Kearney's Physics Department and Research Service Council for support, financially and otherwise throughout this process. Thanks also goes out to the NASA JOVE group for financial support to attend the National Conference on Undergraduate Research.

Analysis of X-ray Sources in Galaxy Clusters

Dean Smith

Department of Physics
University of North Dakota

Faculty Advisor:

Dr. Mark Henriksen

We studied X-ray images of galaxy clusters taken by the ROSAT satellite in an effort to detect, identify, and analyze sources. Galaxies are large systems of stars and gas held together by gravity. The vast majority of galaxies are found in clusters containing many galaxies gravitationally bound together. Most sources of visible light in galaxy clusters are stars. X-rays, being of much higher energy than visible light, are emitted by hot gas in these clusters. Sources could be galaxies in the cluster, clumps of hot gas stripped from galaxies by some process, or distant galaxy clusters. The purpose of our research is to identify and analyze these sources and their environments. Many sources could not be identified, meaning their positions did not correspond to any catalogued galaxy found in optical images. Some unidentified sources are yet to be discovered distant clusters of galaxies. By analyzing the environments of these sources, we hope to learn how they were formed. If gas removal was caused by ram pressure, we would expect more sources in areas of higher gas density. If the cause is tidal interactions with the cluster, we would expect more sources near the center of the cluster.

SOURCE DETECTION

Unlike images in visible light, X-ray images show the hot gas in between galaxies. This cluster emission acts to hide sources. To locate sources in the images, wavelet analysis was used to amplify small variations in the intensity. A function (equation 1) is used to calculate values for a grid representing the pixels in the image. This grid is centered on each pixel and the intensity of each pixel is multiplied by the corresponding grid value. We used the "Mexican Hat" wavelet, shown in figure 1. As you can see, it is sharply peaked and has negative values toward the edges. This works to enhance bright variations and dim small ones. The width of the base, denoted as 'a', is a rough measure of the size of the sources that are best revealed. We used wavelets of for a = 10, 20, 40, 80, and 160 arcseconds to reveal sources on different scales.

$$g\left(\frac{x}{a},\frac{y}{a}\right)=\left(2-\frac{x^2+y^2}{a^2}\right)e^{-(x^2+y^2)/2a^2} \qquad (1)$$

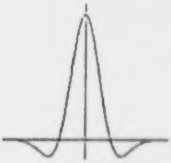

Figure 1: Mexican Hat Wavelet

Contour plots for each convolved image were made showing sources with signal to noise ratios above 3.5. This cutoff was chosen because it has been shown to include very few spurious sources (Grebenev, Jones, Forman 1995). Sources were compared on each plot to find which size wavelet yielded the highest signal to noise ratio. This gave us the approximate radius of the source.

$$size \approx a\sqrt{2} \tag{2}$$

For this project, we are only interested in extended sources since point sources such as stars and quasars are unlikely to be associated with the galaxy cluster. Sources were marked as extended if their approximate size was greater than the full width at half max for a point source. This is the width at a point where the intensity is ½ the maximum. For the ROSAT PSPC instrument, this depends on its distance, θ, from the center of the image.

$$FWHM = \sqrt{409.65/1.2 + 69.28 \cdot 1.2^{2.88} + 66.29 + (.29 \cdot \theta^{1.74})^2 + (2.355 \cdot 1.5)^2} \tag{3}$$

The positions for extended sources were found and compared with the NASA/IPAC Extragalactic Database. This allowed us to separate identified sources from unidentified sources so that we may study the environments of each separately and conclude whether unidentified sources prefer different conditions.

ANALYSIS

While analyzing sources, the goal is to determine the nature of the unidentified sources and the process by which they formed. We hope to do this by examining the environment around these sources to see if they prefer certain conditions. An overabundance of unidentified sources found close to the cluster center, where the gravity is strongest, would suggest tidal interactions as a mechanism. Alternatively a preference for areas of higher gas density would indicate hot gas stripped from galaxies by ram pressure. Gas density is proportional to the square root of the x-ray luminosity. Thus a graph showing both the location and luminosity of the surrounding cluster emission would be a useful tool.

The location can be found from the image and simple trigonometry. The angular separation between the source and the center can be found from the image. To convert this angle to an actual distance, one needs the distance to the cluster. This can be found from Hubble's Law, which describes the expansion of the universe.

$$d = v/H \tag{4}$$

H is the Hubble constant, for which I assumed a value of 65 km/s*Mpc. The velocity, v, can be found from the redshift, z.

$$v = \frac{(z+1)^2 - 1}{(z+1)^2 + 1} c ; c = speed\ of\ light = 3x10^8 m/s \qquad (5)$$

Simple trigonometry can then be used to convert angular measurements to parsecs.

$$r = d \tan(\theta) \qquad (6)$$

The flux for the cluster emission surrounding each source was found by fitting its spectrum with a theoretical model which took into consideration redshift, neutral hydrogen column density, and temperature. The flux is dependent on distance so it was converted to luminosity.

$$L = 4\pi d^2 F \qquad (7)$$

CONCLUSION

Figure 2 is a graph comparing identified and unidentified sources for the galaxy clusters Abell 1367 and Abell 514. As expected, the cluster emission, and therefore the gas density, decreases toward the edge of the clusters. However, unidentified sources do not seem to prefer a different environment than identified ones. At least three more clusters will be analyzed to search for a statistical difference between the two groups of sources.

Using FTIR-Reflection Absorbance Spectroscopy to Study the Structure of Thin Ice Films

Marin S. Robinson

Heterogeneous processing on ice particles plays an important role in the chemistry of the earth's atmosphere. To better understand this chemistry, grazing angle Fourier Transform-Infrared Reflection Absorbance Spectroscopy (FTIR-RAS) is used to study the structure and reactivity of vapor-deposited ice films in a high vacuum chamber. In particular, FTIR-RAS is used to examine the surface roughness of vapor-deposited ice films between 160-185 K. Above 165 K, absorbance spectra show the onset of scattering between 4000-7000 cm^{-1}, a region in which water-ice does not absorb light. Scattering is interpreted as evidence for increased surface roughness. The loss of light due to scattering increases with temperature and film thickness and decreases with deposition rate. Collectively, these data suggest that ice roughens between 165-185 K and that a "rough" surface is lower in energy than a "smooth" one.

BACKGROUND

In recent years there has been considerable interest in the chemistry of ice films. This interest has been stimulated, in part, by the discovery that polar stratospheric clouds (PSCs) play an important role in the ozone depletion leading to the event referred to as the "ozone hole." The water-ice clouds re-partition the large reservoir of unreactive chlorine species (HCl and $ClONO_2$) to more reactive forms (HOCl and Cl_2) that can go on to destroy ozone.[1] Type II PSCs, composed largely of water-ice, appear to be more efficient in this interconversion process than their Type I counterparts, composed of water-ice, nitric acid and sulfuric acid. While the reasons for this are still under investigation, this finding suggests that the pure water-ice surface is more chemically reactive than an ice surface that has been passivated with HCl or H_2SO_4.

What is it about the surface structure of ice clouds that make them so reactive? This question has prompted scientists to investigate both the chemistry[2-5] of water-ice as well as the structure and morphology[6-11] of the crystalline ice surface. Laboratory-based studies typically use ice films to simulate ice particles in clouds. While not a perfect match, it is reasonable to assume that ice films capture the significant reactive properties of their ice-cloud counterparts. Initial theories postulated that the reactivity may be due to "dangling bonds," or non-hydrogen bonded OH groups at the surface of water-ice films. Experimental evidence, however, suggests that the number of dangling bonds at the surface of ice films deposited at temperatures approaching those of the stratosphere (> 160 K) are few to none.[7,11] Indeed, the surface appears to be a dynamic and mobile one. Haynes et al.[12] have suggested that above 180 K, between 10-1000 monolayers of water are evaporated and condensed each second. Even studies done at much colder temperatures (90 K) indicate that the upper most layer of water molecules vibrate more rapidly than the underlayers, indicative of increased mobility.[13] Moreover, both experimental[14] and theoretical[6] data suggest that the surface structure of ice at temperatures above 180 K becomes rougher and more disordered. If surface roughness does increase, so does the amount of exposed surface area. Since surface area is a parameter needed to determine gas uptake coefficients of molecules on ice.[15] it is important to have a well-characterized film surface.

In this work, grazing-angle Fourier Transform Infrared-Reflection Absorbance Spectroscopy (FTIR-RAS)[16] is used to study the morphology of water-ice films at temperatures approaching those in the stratosphere. In accord with works by Keyser[14] and Devlin,[6] results indicate that ice becomes more disordered as deposition temperatures increase above 160 K. The infrared scattering signature of water-ice (between 7000-4000 cm^{-1}) is used to infer roughness, where increased scattering corresponds to a rougher surface. Specifically, the dependence of the scattering signature on temperature, film thickness, and deposition rate is analyzed. The implication of this work on the heterogeneous processing of ice films is discussed.

EXPERIMENTAL

All experiments were conducted in a newly constructed FTIR-RAS apparatus. Briefly, the high vacuum instrument (base pressure = 8×10^{-8} Torr) consists of two stainless steel chambers separated by a gate valve. The top chamber supports a vertically mounted, optically flat aluminum (Al) substrate (d = 6.4 cm) upon which water-ice is condensed, KBr windows for the passage of infrared light, a Bayard-Albert ionization gauge, and a Baratron capacitance manometer. The ionization gauge pressure (P_{IG}) was calibrated for water using the absolute pressure of the capacitance manometer (P_{CM}), resulting in $P_{CM} = 1.15 \times P_{IG}$. Errors in pressure are estimated to be ± 15%. The bottom chamber houses an Edward's diffusion pump (230 L/s) and two precision leak valves (Lesker). Water is introduced through a leak valve after undergoing at least three freeze/pump/thaw cycles on an attached vacuum glass line.

Infrared spectra were collected using a Nicolet 550 Magna II FTIR spectrometer with a silicon-carbide source and a liquid nitrogen cooled HgCdTe detector. Spectra represent the co-addition of 16 scans at 4 cm^{-1} resolution. At grazing-angle the infrared light reflects off the aluminum substrate at 83° from normal (Fig. 1). The substrate is cooled through thermal contact with a liquid nitrogen filled cryostat, then resistively heated to the desired temperature using a programmable temperature controller. The substrate temperature is measured using a T-type (copper-constantan) thermocouple. Radial gradients across the surface are ≤ 2 K, and absolute temperatures are within ± 2 K. The Al surface is vacuum-sealed into a differentially pumped stainless steel sleeve maintained at temperatures above the ice frost point. In this way, the Al substrate is the only surface in the chamber cold enough to condense ice. Ice deposition rates were determined according to the equation[17]

$$dx/dt = \alpha P/[\rho(T)(2\pi m k T_g)^{1/2}] - [v_0/\rho(T)]\exp[-E_d/RT_s] \qquad (1)$$

where α is the estimated sticking coefficient ($\alpha = 1$),[17] P is the partial pressure of water, $\rho(T)$ is the temperature dependent density of the ice ($\rho = 0.93$ g/cm^3),[12] v_0 is the zero-order desorption pre-exponential (2.8×10^{30} molecules/(cm^2 s)),[12] m is the molecular weight of H_2O (18.016), T_g is the impinging gas temperature (298 K), k is the Bolzmann constant, E_d is the desorption activation energy (48.12 kJ/mol),[12] and T_s is the substrate temperature. Thus, for example, for $P = 1.0 \times 10^{-5}$ Torr and $T_s = 165$ K, dx/dt = 1 nm/s.

Film thickness (d) was determined by comparison of the observed infrared absorption spectra with absorption spectra derived theoretically.[16] At grazing incidence, spectral peak shapes undergo characteristic changes with thickness that make the assignment of film thickness relatively straightforward. Errors in film thickness are estimated to be ± 20%.

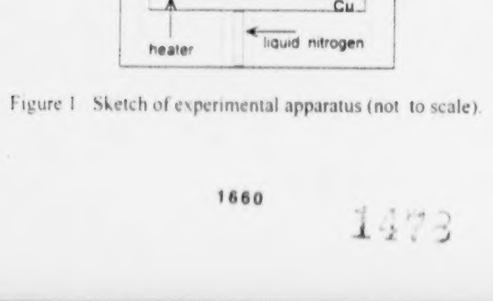

Figure 1 Sketch of experimental apparatus (not to scale).

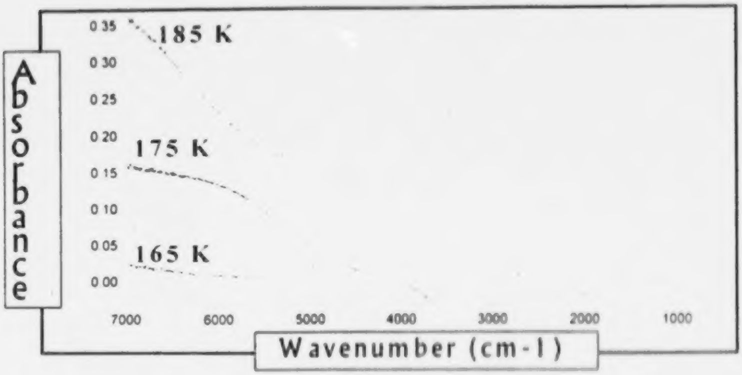

Fig. 2. Preliminary water-ice absorbance spectra which illustrate the changes in scattering (7000-4000 cm^{-1}) with temperature. Films are ~ 600 nm thick and were deposited at ~ 1 nm/s

RESULTS AND DISCUSSION

Changes in the absorbance spectra of water ice films as a function of temperature (Fig. 2), growth rate (Fig. 3), and film thickness (Fig. 4) were examined. Specifically, changes were examined in the scattering region of the spectra (7000-4000 cm^{-1}) where water-ice does not absorb infrared light. As shown in Fig. 2, the absorbance due to scattering increases as the substrate temperature at deposition is increased from 165 K to 185 K. Fig. 3 indicates that there is a slight increase in scattering when ice is vapor-deposited at 1 nm/s (slow) rather than at 10 nm/s (fast). This result is slightly more pronounced at 175 K than 185 K. Finally, in Fig. 4, more scattering is observed in thick films (600 nm) than in thin ones (100 nm).

Any increase in scattering is interpreted as evidence for ice film roughening. A rougher, more disordered and particle-like surface presumably scatters light more efficiently than a smooth and ordered one. Given this assumption, results indicate that ice films become increasingly rougher (more particle-like) at temperatures above 165 K. This observation suggests that a rough surface is lower in energy than a smooth one. Water molecules must overcome a barrier to rearrangement before the surface can "roughen," hence roughness is observed only at the warmer temperatures. This interpretation is further supported in the growth rate data. Under conditions of slow growth, water molecules with sufficient energy to diffuse have more time to sample the surface before they are buried by incoming adlayers, thereby increasing their probability of finding a more favorable (lower) energy site. The

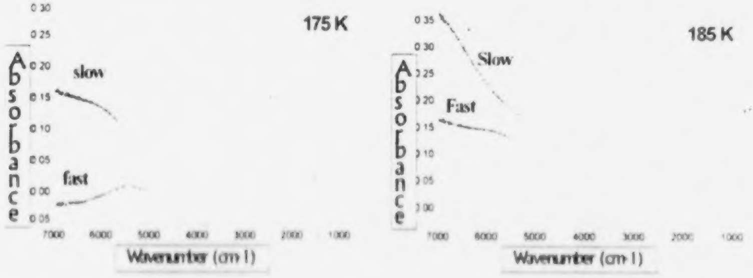

Fig. 3. Preliminary water-ice absorbance spectra which illustrate the changes in scattering (7000-4000 cm^{-1}) with growth rate at 175 K and 185 K. Films are ~ 600 nm thick.

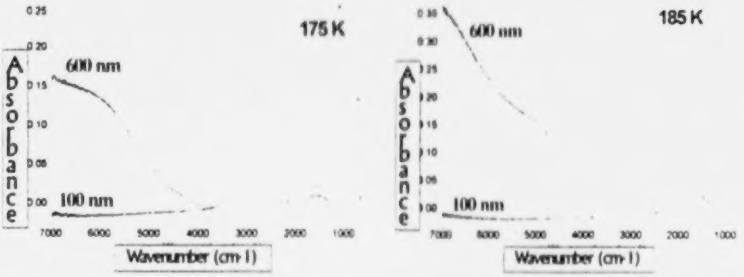

Figure 4. Preliminary water-ice absorbance spectra which illustrate the changes in scattering (7000-4000 cm^{-1}) with film thickness at 175 K and 185 K. Films were deposited at ~ 1 nm/s.

growth rate dependence is most pronounced at 175 K, where more time allows more molecules to make it over the diffusion barrier. At 185 K, most water molecules have sufficient energy to traverse the barrier, hence the growth rate dependence is less pronounced.

As shown in Fig. 4, scattering also increases with film thickness. This finding suggests that a rough surface retains its disordered character as it is buried by incoming adlayers. Thus, light entering the film encounters fissures, cracks, and irregularities within the bulk structure. Multiple encounters with such irregularities increase the probability of light scattering, since a thick film has more chances to scatter the incoming (or outgoing) light than a thin one.

CONCLUSIONS

Results suggest that ice films roughen at temperatures characteristic of the earth's stratosphere (> 188 K), in accord with recent experimental[14] and theoretical work.[6] This roughening is of interest both to physicists interested in the fundamental properties of ice, as well as to the atmospheric community. Roughness can influence the heterogeneous processing of ice films, both with respect to their ability to adsorb gases (sticking coefficients) as well as their chemical reactivity. In future work, the dependence of scattering on angle of incidence and light polarization will be examined. In addition, efforts will be made to quantify how increased scattering correlates to changes in the surface area of the ice film.

Large DNA Fragment Sizing by Flow Cytometry

Angela R. Cameron

Department of Chemistry
Furman University
Greenville, SC 29613

Faculty Advisor:
Dr. Jeffrey T. Petty

ABSTRACT

In previous research, sizing fragments using laser flow cytometry was successfully applied to small DNA fragments ranging from 1.5 to 150 kilobase pairs (kb) (Goodwin et al.). The focus of this research was the sizing of large DNA fragments ranging in size from 50 to 2000 kb. Cohesive termini of bacterial DNA and viral DNA were ligated in order to create large oligomers. These large DNA fragments were analyzed using the following techniques: agarose gel electrophoresis, pulsed field gel electrophoresis, and laser flow cytometry. The goal of this research was to demonstrate that the size of ligated DNA fragments could be measured more accurately, consistently, and with greater ease using the laser flow cytometry method than by other methods.

INTRODUCTION

Laser flow cytometry and PFGE have the ability to bridge the resolution gap between cytogenetic methods (>5Mb) and DNA analysis (<50-100kb). These methods could prove to be a powerful tool in diagnosis of chromosomal rearrangement. There are two main areas of practical applications to medical genetics: (1) detection of affected chromosomes in genetic disease, and (2) detection of chromosomal malignancies due to deletions and translocations involving oncogenes (Van Ommen et al.)

Pulsed Field Gel Electrophoresis

Agarose gel electrophoresis uses a three dimensional polymer network to separate charged biological macromolecules based on the magnitude of the electric field, the net charge of the molecule, and the size and shape of the molecule as characterized by its frictional coefficient (Tinoco). DNA molecules greater than 50kb have gel electrophoresis mobilities independent of their length due to reptation. The solution to this problem was to make DNA molecules change direction during electrophoresis by using a pulsed field that alternates in direction. The problem with this method is that it takes from 16 - 24 hours to run one gel experiment.

Laser Flow Cytometry

To circumvent this problem flow cytometric DNA sizing was developed which is based on measurement of fluorescence intensity from single fragments stained with noncovatlently bond dye (Petty). Individually TOTO-1 stained DNA fragments passed through a low power, focused, continuous laser beam. Fluorescence bursts were recorded and the collected data was used to create a histogram that allows sizing of DNA fragments (Figure 1). The DNA-dye interaction is probably noncovalent. There are two contributions to the interaction: electrostatic attraction and intercalataion.

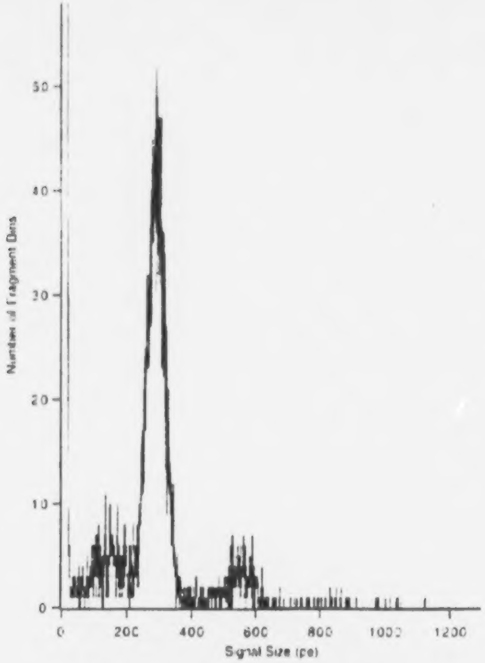

Figure 1: Histogram of λ DNA

Ligation of Cohesive Termini

Ligation involves formation of new bonds between phosphate residues located at the 5'-terminal of double stranded DNA and adjacent 3'-hydroxyl moieties. The formation of the phosphodiester bonds between adjacent 5'-phospate and 3'-hydroxyl residues was catalyzed by bacteriophage T4 DNA ligase. Ligation is a biomolecular reaction whose velocity under standard conditions is determined solely by the concentration of compatible DNA termini (Maniatis). At low concentrations of DNA, recircularization of the plasmid DNA will occur with high efficiency. At higher concentrations the initial products of ligation will be dimers and larger oligomers of the plasmid because a given end of DNA is more likely to encounter a terminus located on another molecule before intramolecular ligation occurs. j/i ratios were used to calculate the appropriate DNA concentrations where $j/i = (51)/([DNA](MW)^{1/2})$ (Dugaiczyk). When $i>j$, linear oligomers are favored. When $i<j$, recircularization should occur.

MATERIALS AND METHODS

There were two types of ligation reactions: ligation of λ DNA and ligation of SV40 DNA. There were three types of analyses: agarose gel electrophoresis, PFGE, and laser flow cytometry. The ligation of λ DNA was analyzed using PFGE and laser flow cytometry. Ligation of SV40 was analyzed using gel electrophoresis and laser flow cytometry.

Ligations using T4 Ligase

The following materials were added to five cuvettes: 8μL sterilized water and 2μL 5X T4 ligase buffer. Next, 2μL λ DNA of varying concentrations was added to the cuvettes (Table 2).

Table 2: Concentration of λ DNA used during ligation reactions.

Cuvette Number	Concentration of DNA (μg/μl)
1	0.5
2	0.25
3	0.005
4	0.0005
5	1.0

The cuvettes were gently spun in a centrifuge. They were then heated in a 65°C water bath for 20 minutes. 1.0-2.0mg of DTT was then added to each cuvette. 2μL T4 DNA ligase was added to each cuvette. The cuvettes were centrifuged gently and then placed in a 4°C refrigerator overnight. These samples were then analyzed using PFGE and flow cytometry.

For the PFGE, a 0.6% agarose gel was made. 2μL from each ligation reaction were loaded in adjacent lanes. In the three remaining lanes, 2μL of each of the following size markers were loaded: coliphage T4 DNA, coliphage T5 DNA, and the λ pulse marker® DNA. The gels was run at 145 volts for 13 hours with a 3 second positive pulse and a 1 second negative pulse. A pump was used to circulate the buffer through plastic tubing which was immersed in a 15°C water bath. The gel was stained in a 0.5μg/μL ethidium bromide bath for 30 minutes and then photographed.

The DNA was analyzed with laser flow cytometry. The fragments were first reacted with TOTO. The contents of each cuvette, were stained, diluted, and run through the laser separately. To stain the DNA, 180μL TE and 0.2μL TOTO was added to the cuvette. It was allowed to sit for 30 minutes to allow the dye to interact with the DNA. It was then loaded into the syringe for injection. Five base pairs of DNA to one TOTO dye is the protocol for staining. For analysis with the laser the optimal concentration is 1 X 10^{-13}moles of fragments per liter. Once optimal flow was achieved, data, in the form of bursts (Figure 2), was collected and then converted into a histogram.

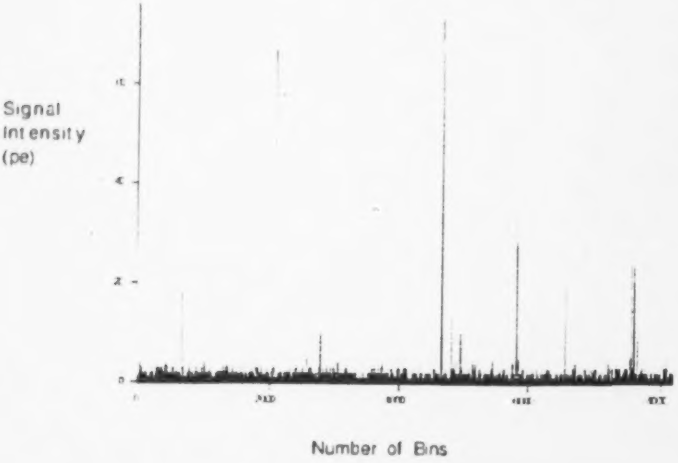

Figure 2: Observed Fluorescence from large λ oligomers: fluorescence was reduced by 1000x, and very large fluorescence bursts were still observed.

Ligation of SV40 DNA

A similar approach was used in the ligation of SV40 DNA. However, before the ligation was performed, the DNA was cut with EcoRI restriction enzyme. It was necessary to cut the SV40 DNA with the restriction enzyme in order to create the "sticky ends" necessary for the creation oligomers. After ligation, the DNA was analyzed using agarose gel electrophoresis and laser flow cytometry.

RESULTS AND DISCUSSION

Lambda DNA

Simple gel electrophoresis did not separate the λ DNA into the ladder of fragments. However, it was not expected to work because the oligomers were greater that 50kb. This separation problem should have been corrected with the use of the field inversion, but it was not. There are two possible reasons why this could have occurred: (1) The PFGE apparatus was not working properly, and/or, (2) the ladder of fragments were not produced. Computer modeling of the reptation motion of DNA during PFGE allows for the calculation of the optimum pulse length to separate a given size range (Smith et al.) In this model, the molecule was represented by a chain of charged beads connected by entropic springs, and the gel was represented by a segmented tube surrounding the beads. This model predicted that for a 20V/cm electric field, a migration in the positive direction of 3 seconds and a migration in the opposite direction for 1 second should give a good separation in the size range of 50kb to 2000kb, the target range for this research. In order to check if the field inversion pulse times or the temperature of the buffer contributed to the problem of separation, these parameters were changed systematically. Changing these parameters had little effect on the separation. In most of the gels either one or two discrete bands were observed in the lanes containing the lambda concatomers. The gel size markers used during the PFGE experiment indicated that the size the DNA was greater that 170kb. This means that λ concatomers were formed. It can be concluded from this that something was occurring in the reaction tube that resulted in the favorable production of one or two specific concatomer lengths. This leads to the possibility that, do to the statistical nature of the reaction, concatomers of a specific length are somehow favored over the formation of concatomers of random length which produce the ladder. This theory was substantiated be data from the laser. The histograms of all of the lambda concatomers generally detect two distinct sizes of concatomers. At first, the DNA was so fragmented after delivery to the laser beam, that initial experiments proved unsuccessful. More dilute samples were used and the problem of fragmentation was not as pronounced.

SV40 DNA

The same problems that were experienced using the lambda DNA were experienced with the SV40 DNA. Gel electrophoresis generally produced two bands. The histogram showed that there were concatomers there, but no distinct sharp peaks were seen. The purpose of using SV40 was to cut down on the problems associated with fragmentation because SV40 is much smaller than lambda.

CONCLUSION

Even though gel electrophoresis and PFGE did not successfully produce a lambda ladder, there was evidence that concatomerization did take place. Based upon this it was reasonable to conclude that the experimental problems resulted from an imperfect apparatus set-up. The laser experiments proved promising. In changing the delivery system to electroosmotic flow, the problem of fragmentation upon delivery to the system should be alleviated. The electroosmostic injection system works by using an electric current to move the DNA into the laser beam. This is a more gentle was to deliver the DNA. This research clearly demonstrates that there are inherent problems with the use of PFGE for this specific experiment

1485

as well as in general. Although past PFGE research shows adequate separation of large DNA fragments, there are too many questions left unanswered. Disadvantages to PFGE include: 16 hours to run, cannot size supercoiled or open circular DNA, and reproducibility and accuracy from gel to gel was difficult to replicate. Advantages to laser flow cytometry include: rapid acquisition of data (less that three minutes), sensitivity (0.4pg compared to 0.2μg), measures both linear and supercoiled DNA, and can measure fragment length as well as the number of fragments.

β-Cyclodextrin has been shown to significantly improve the *endo* diastereofacial selectivity in the aqueous Diels-Alder reaction of (*l*)-menthyl acrylate with cyclopentadiene.

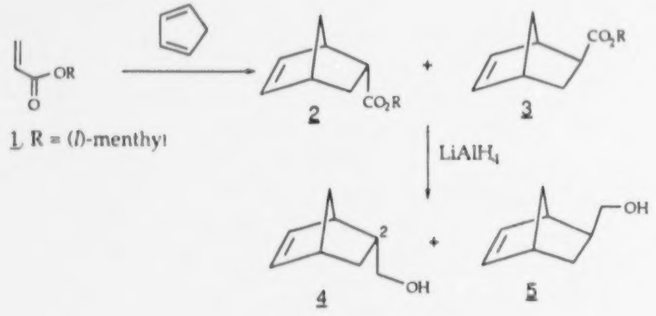
BACKGROUND

Because of increasing efforts in environmental conservation, there has been an interest to develop organic reactions that can be performed in environmentally friendly solvents, such as water (Li, 1993; Lubineau et al., 1994). Through the work of Rideout and Breslow (1980), Breslow et al. (1983; 1984), Grieco et al. (1986), Lubineau et al. (1985; 1986), Schneider and Sangwan (1986; 1987), and Sternbach and Rassana (1982), it has become apparent that the course of Diels-Alder reactions can be markedly influenced by the use of aqueous solvents, including the use of various modifiers such as salts (Breslow et al., 1984), acids (Otto and Engberts, 1995; Kobayashi et al., 1993), and inclusion complexes such as β-cyclodextrin (Breslow and Maitra, 1984). Due to a combination of solvophobic forces and/or intracavity inclusion in the cyclodextrin, aqueous Diels-Alder reactions have been shown to have an increase in the rates of reaction and *endo* selectivity (Schneider and Sangwan, 1982; 1985; Sternbach and Rassana, 1982). Breslow and coworkers (1980; 1983; 1984) and Schneider and Sangwan (1982; 1985) have further demonstrated that the products from reactions of simple dienophiles with cyclopentadiene in the presence of β-cyclodextrin show some enantioselectivity. For example, in the reaction of methyl vinyl ketone and acrylonitrile with cyclopentadiene, the *endo* adducts of both reactions were reported to have a few percent enantiomeric excess (e.e.) (Breslow and coworkers (1980; 1983; 1984).

As part of our interest in developing methods to enhance the diastereofacial selectivity in aqueous Diels-Alder reactions, we have studied the reaction of (*l*)-menthyl acrylate with cyclopentadiene under various aqueous conditions. These reactions were done in the presence of either a salt (lithium chloride), or a Bronstead-Lowry acid (hydrochloric acid) (Otto and Engberts, 1995) or a Lewis acid (scandium triflate) (Kobayashi et al., 1993), or β-cyclodextrin (Breslow and coworkers, 1980; 1983; 1984). For comparison, the reactions were also performed under "neat" conditions, and in methylene chloride solutions, either in the presence or absence of titanium (IV) chloride. The reaction of (*l*)-menthyl acrylate 1 with cyclopentadiene was chosen as our model for this investigation because it has been widely studied (Lee et al., 1995; Farmer and Hamer, 1966; Oppolzer et al., 1981) even under aqueous conditions (Cativiela et al., 1992). Specifically, using a 60% methanol:water mixture the ratio of *endo*:*exo* products was reported to be 9:1, and the diastereomeric excess (d.e.) of the *endo* product was 13.7% (Cativiela et al., 1992).

RESULTS AND DISCUSSION

In our studies, as depicted in Scheme 1, all reactions were performed using an excess of 2.5 mole equivalents of freshly cracked cyclopentadiene to each mole of acrylate 1. The relative amounts of the *endo* 2 and *exo* product 3 were determined by GC analyses (see Figure 1). The retention times for these *endo* and *exo* isomers were 27.5 min and 28.5 min, respectively. For the "neat" reaction (entry 1 in Table 1), the ratio of the *endo:exo* products was verified by reduction of the products with lithium aluminum hydride to yield the diastereomeric alcohols 4 and 5. The ratio of these *endo:exo* alcohols was found by a ^{1}H-NMR analysis to be 3:1, respectively. In our studies, the *endo* product was produced preferentially, and in the case of the titanium (IV) chloride and hydrochloric acid catalyzed reactions (entries 3 and 6), virtually no *exo* product was observed. This observation is not surprising because both these reagents have been shown to significantly enhance the *endo* selectivity in Diels-Alder reactions (Otto and Engberts, 1995; Lee et al., 1995; Farmer and Hamer, 1996; Oppolzer et al., 1981). For all of the other aqueous reaction conditions, the effects on *endo* selectivity was small.



Scheme 1. Synthesis of Alcohols 4 and 5

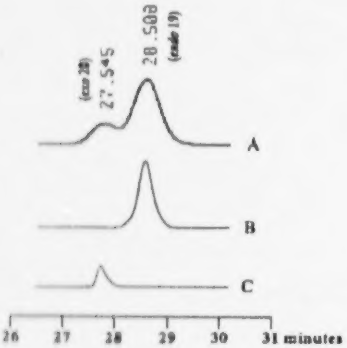


Figure 1. GC Chromatograms of Adducts 2 and 3

The isomeric adducts 2 and 3 were separated by silica gel column chromatography, and their structures were unambiguously characterized by IR and ^{1}H-NMR spectroscopic studies (Otto and Engberts, 1995; Lee et al., 1995; Farmer and Hamer, 1996; Oppolzer et al., 1981). The *endo* adduct 2 from the titanium (IV) chloride catalyzed reation was reduced with $LiAlH_4$ to alcohol 4, and its specific optical rotation was determined to be *plus*, indicating that the absolute configuration of the major enantiomer was 2R (Lee et al., 1995; Oppolzer et al., 1981).

[a] The major diastereomer has the 2R configuration in all cases.

The diastereomeric excess (d.e.) values for the reactions in Table 1 were determined by ^1H-NMR analyses of the purified *endo* product 2 (see Figure 2) using integration of the signals of the diastereomeric olefinic protons at 5.87 ppm (for the major 2R-(*l*)-menthyl diastereomer) and 5.92 ppm (for the minor 2S-(*l*)-menthyl diastereomer).

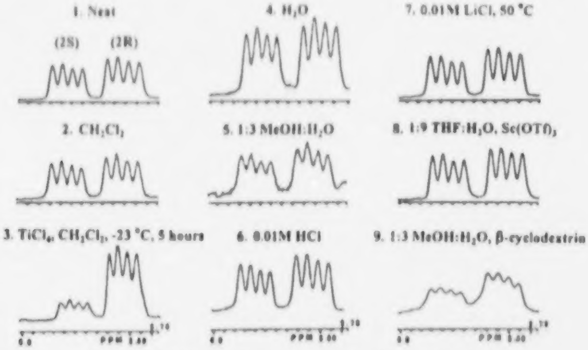

Figure 2. 300 MHz ^1H-NMR analysis of adducts 2 and 3

As expected, the titanium (IV) chloride catalyzed reaction gave the highest d.e., and this could be attributed to stabilization of the *s-trans* conformation of acrylate 1 by the Lewis acid (Lee et al., 1995; Farmer and Hamer, 1966; Oppolzer et al., 1981). The aqueous reactions (entries 4 and 5) did not show significant increase in diastereofacial selecitivitiy over the neat (entry 1) and methylene chloride (entry 2) reactions, although in the presence of methanol a slight increase in *endo* selectivity was observed. The lithium chloride promoted reaction (entry 7) also did not improve either the d.e. value or the *endo* selectivity. The use of scandium (III) triflate (entry 8), a water stable Lewis acid (Kobayashi et al., 1993), also did not produce any enhancement in the d.e value. However, the percent chemical yield of 2 was increased. Hydrochloric acid (entry 6) had a dramatic effect in raising the chemical yield of 2, *endo* selectivity, as well as a small increment on the d.e. value. These effects could be due to protonation of the acrylate (Otto and Engberts, 1995). The highest diastereofacial selectivity in the aqueous reactions studied was the β-cyclodextrin promoted reaction (entry 9), which gave a 27 percent d.e. This reaction also produced an enhanced *endo* selectivity over the water reaction (entry 4). The low chemical yield for this reaction was due to the large volume of solvent used, and some of the products being trapped in the sugar cavity. In a separate β-cyclodextrin promoted reaction (entry 10), when the volume of solvent was reduced, and the percent recovery of product improved; but, with the use of a 1:1 water:methanol solution, the value of d.e. was slightly reduced to 19 percent.

The above results on the aqueous reactions indicate that the course of the stereo and diastereofacial selectivities of Diels-Alder reactions performed in aqueous conditions can be influenced by the type of solvents and modifiers used. With these encouraging results, our efforts are now turned towards investigating aqueous Diels-Alder reactions using dienophiles that are devoid of the *s-cis* and *s-trans* isomerization problem, and also at reactions wherein the rates can be accelerated by the presence of water and cyclodextrins.

EXPERIMENTAL

General Procedure for the reactions given in entries 1,2,4-8, 10.

A solution of acrylate 1 (76 mg, 0.36 mmol) was made up in the appropriate solvent (5 mL), except no solvent was used for the "neat" reaction, and for entry 10, 14 mLs of solvent was used. Also in entry 10, β-cyclodextrin (331 mg, 0.29 mmol) was added. The reaction vial was sealed and the solution was vigorously stirred. Freshly cracked cyclopentadiene (75 μL, 0.55 mmol) was added. After stirring at room temperature for 24 hrs, the reaction was extracted with chloroform (3 times, 25 mL each). In the β-cyclodextrin reaction, the reaction was first filtered and then the filtrate was extracted. The combined organic extracts were dried (sodium sulfate) and concentrated. The crude product was analyzed by GC with FID detection; crosslinked methyl silicone gum column (25m x 0.53 mm i.d.); nitrogen carrier gas at 15 psi, injector temperature 230°C; detector temperature 250°C; oven temperature was programmed from 190°C (held for one min) at 2°C min^{-1} to 180°C, and then 1°C min^{-1} to 170°C (held for 24 min). Retention time for the *endo* product 2 was 28.5 min, and for the *exo* compound 3 the retention time was 27.5 min.

The products were purifired on a silica gel column using a 0-2% ethyl acetate:hexanes solvent with the *exo* product eluting first. For the *endo* product 2: TLC (5% EtOAc/hexane) R_f 0.32. ^{1}H-NMR ($CDCl_3$): For the major diastereomer (2R) of some of the resolved signals: δ 6.20 (dd, 3.0, 5.7, 1H), 5.87 (dd, 2.7, 5.4, 1H), 4.58 (dt, 6.2, 12.3, 1H); for the minor (2S) diastereomer 6.18 , 5.92, and 4.60. IR (Neat): ν 3063, 2954, 2867, 1730, 1632, 1453, 1365, 1333, 1273, 1175, 1104, and 1022 cm^{-1}. For the *exo* isomer 3: TLC (5% EtOAc/hexane) R_f 0.45. ^{1}H-NMR ($CDCl_3$): Signals for the diastereomers on 3 were not resolved: δ 6.13 (dd, 3.0, 5.6, 1H), 6.09 (dd, 3.0, 5.6, 1H), 4.73 (dt, 4.3, 10.8, 1H). IR (Neat): v 3075, 2955, 2870, 1732, 1632, 1455, 1370, 1333, 1261, 1170, 1097, 1038 cm^{-1}.

Lithium aluminum hydride reduction of adducts 2 and 3 from entry 1 (see Lee et al., 1993)

Alcohols 4 and 5 were obtained in 78% yield. ^1H-NMR of alcohol 4: ($CDCl_3$): δ 6.15 (dd, 3.0, 5.7, 1H), 5.96 (dd, 2.8, 5.7, 1H). For 5: 6.11 (d, 2.9, 5.5, 1H), 6.07 (dd, 2.8, 5.6, 1H).

D. Allan Butterfield

Beta amyloid peptides are believed to be a part of the mechanism of oxidative stress in Alzheimer's disease. These peptides have been shown to be responsible for membrane lipid peroxidation. Two products of this lipid peroxidation are 4-hydroxy-2-trans-nonenal (HNE) and malondialdehyde (MDA). The effects of HNE and MDA on erythrocyte membranes were previously unknown. In this study, the effects of HNE and MDA on erythrocyte membrane protein conformation were tested by employing the method of electron paramagnetic resonance (EPR), with the help of a protein specific spin label, MAL-6. Prevention of membrane damage by HNE and MDA was also tested with the use of glutathione ethyl ester (GEE). At concentrations of 5μM and 50μM, both HNE and MDA proved to be toxic. HNE and MDA were each more toxic at the higher concentration, 50μM. A 2mM solution of GEE prevented the protein conformational changes caused by both 50μM HNE and MDA. These results are discussed with relevance to oxidative stress in Alzheimer's disease.

INTRODUCTION

Alzheimer's disease, a neurodegenerative brain disorder, is characterized by the presence of senile plaques in the brain tissue of afflicted individuals. These senile plaques have been shown to contain aggregations of amyloid beta peptides (Aβ) (1,2,3). Our laboratory showed that Aβ is associated with free radical oxidative stress (4,5). Besides the initial damage caused by protein oxidation and lipid peroxidation, products of these processes can also be toxic to cells and may also contribute to cellular damage or death (9).

Two aldehyde products of free radical-induced lipid peroxidation are 4-hydroxy-2-*trans*-nonenal (HNE) and malondialdehyde (MDA) (10). It has been found that the level of the lipid peroxidation product, HNE, increases greatly in cultured hippocampal neurons in the presence of Aβ peptides (10). HNE and MDA are reactive aldehydes which can interact with membrane proteins. HNE and MDA are electrophiles that attack nucleophilic sites on amino acids and consequently alter protein conformation (11). HNE has been found to be much more reactive than MDA (9). In studies on the effects of HNE on membrane proteins, it has been shown that HNE can even change protein conformation by cross linking membrane proteins (12).

This study employed human erythrocyte membranes as the source of membrane proteins. Erythrocytes are unique in that they have a higher protein to lipid ratio than most cells. Erythrocytes also have an extensive network of cytosolic membrane proteins. It is this protein network and high protein content which make erythrocytes a good model in the study of the effects of HNE and MDA on the conformation of membrane proteins.

This study also employed the use of glutathione ethyl ester (GEE). The ethyl ester form of glutathione allows the glutathione molecules to penetrate the cell membrane and enter the cytosol. Glutathione is a tripeptide antioxidant that can combat the effects of some reactive species. HNE and MDA have been shown to react with thiol compounds such as glutathione (9), and it is this reaction which serves to protect cell membrane proteins from attack by HNE and MDA. Glutathione has previously been shown to form an adduct with HNE (13), and neuronal death caused by HNE decreases with the treatment of GEE (10).

The effects of HNE and MDA on protein conformation can be evaluated through the use of electron paramagnetic resonance (EPR) techniques of spin labeling. EPR is a good method for studying such protein conformational changes because EPR is sensitive to small changes in protein conformation and opaque samples can be studied. In order to detect these protein conformational changes, a protein specific spin label, MAL-6, was used to label the erythrocyte membranes. EPR with a MAL-6 label has been used is previous studies to determine the effects of toxins on protein conformation (14,15).

The purposes of this study were to determine: a) if HNE and MDA caused protein conformational changes in erythrocyte membranes; b) the dose response effect of HNE and MDA; and c) whether membrane proteins were protected from HNE and MDA toxicity by GEE. We found that HNE and MDA caused protein conformational changes at both 5µM and 50µM concentrations, and these changes were the greatest at the 50µM concentration. HNE showed a greater toxicity than MDA. We also found that GEE provided protection to the erythrocyte membrane proteins against the effects of HNE and MDA at both concentrations.

MATERIALS AND METHODS

Human blood was obtained from healthy donors by venipuncture and placed in heparinized tubes and immediately put in ice. Ghosts were prepared and spin labeled with MAL-6 as previously described (15). Briefly, intact red blood cells were diluted with 10 volumes of phosphate buffered saline (PBS: 5 mM sodium phosphate (mono- and di- basic) and 150 mM sodium chloride; pH 8.0). Samples were washed 3 times in PBS by centrifugation at 600 X g for 5 minutes at 4°C. Following each wash the buffy coat and the supernatant were removed by aspiration. Hypotonic lysis in 5P8 (5 mM potassium phosphate (mono- and di- basic)) buffer yielded the erythrocyte membranes. Cells were treated with 20 volumes of 5P8 and incubated for 30 minutes and subsequently centrifuged at 4°C and 27,000 X g, for 10 minutes. The process was repeated until all the hemoglobin was removed. The protein concentration of the ghosts was determined by methods described by Lowry et al. (16) and was adjusted to 8 mg/ml. At this point the ghosts were treated with either 5 or 50 µM HNE or MDA. Controls were treated with the vehicle for HNE and MDA, i.e., ethanol. The incubation was carried out for 60 minutes. The samples then were diluted to 3 mg/ml and spin labeled with MAL-6 as previously described (15). One volume of sample was added to 51 mM MAL-6 in 5P8 and incubated for 14-16 hours at 4°C. Excess spin label was then removed by washing six times with 5P8 and centrifuging each time at 27,000 X g and 4°C.

GEE effects were studied with the following procedure. The samples were divided into six aliquots. One aliquot was treated with ethanol alone. The second aliquot was treated with 50 µM HNE. The third aliquot was treated with DMSO, which was used as the vehicle for the glutathione ethyl ester (GEE), and ethanol, and the fourth aliquot was treated with ethanol, DMSO, HNE and GEE. The fifth aliquot was treated with 50µM MDA. The sixth aliquot was treated with ethanol, DMSO, MDA, and GEE. The samples were pre-treated with the GEE to give a final GEE concentration of 2 mM. This incubation was carried out for 3 hours. After this time 50 µM HNE or 50 µM MDA was added and further reaction continued for 1 hour. The samples were then centrifuged, spin labeled, and later analyzed with EPR spectroscopy, as described previously (14).

RESULTS

Analysis with EPR spectroscopy using MAL-6 leads to a spectrum that reflects membrane protein conformation. Two kinds of MAL-6 labeling sites are found in erythrocyte proteins: those in which the motion of the spin label is severely restricted (S sites) and those in which the motion of the spin label is only weakly immobilized (W sites). An EPR spectrum can be analyzed for changes in protein conformation by measuring the ratio of the low field resonance line intensity of the weakly immobilized spin label to that of the strongly immobilized spin label. Decreases in this W/S ratio have been found to correlate with alterations in protein conformation, and this alteration in protein conformation is a measure of toxicity. In all measures of oxidative stress thus far studied in our laboratory, including free radical generation, stroke, hyperoxia, accelerated aging, and Alzheimer's disease [reviewed in (17)], a common pathway, i.e., HNE production and subsequent reaction with proteins might explain this.

The first part of this study investigated the dose dependent effect of HNE on erythrocyte membrane protein conformation (Figure 1). The 5µM samples (n=6) showed an average W/S decrease of 8.5 ± 2.5%. Samples (n=6) treated with 50µM HNE showed a W/S decrease of 15.7 ± 3.7%. It is clear that higher levels of HNE (50µM) are substantially more toxic than low levels of HNE (5µM). The results for MDA were similar: the 5µM MDA samples (n=4) showed a decrease in W/S of 4.1 ± 1.85, while 50µM MDA (n=4) led to a W/S decrease of 15.7 ± 3.7%. Both are more toxic at high concentrations (50µM) than at low concentrations (5µM) (Figure 1).

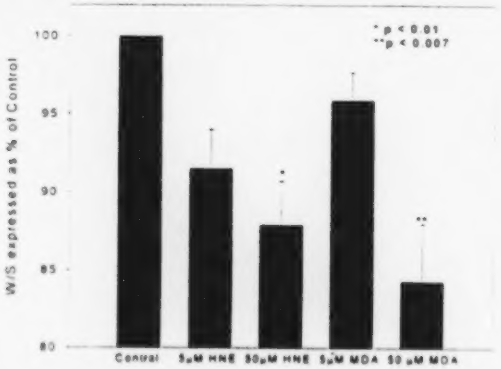

Figure 1: MAL-6 labeled Erythrocytes treated with HNE or MDA

The final part of this research focused on the antioxidant glutathione ethyl ester (GEE) (Figure 2). Samples (n=3) treated with GEE alone did not show a decrease in W/S ratios. Samples treated with 50µM HNE showed a W/S decrease of 11.7 ± 0.8%, while GEE treated HNE samples showed a reduction in decrease to only 2.0 ± 1.1%. Samples treated with 50µM MDA showed a W/S decrease of 9.0 ± 0.9%, while GEE treated HNE samples showed a reduction in decrease to only 1.0 ± 1.1%. These results demonstrate that GEE did, in fact, prevent erythrocyte membrane protein conformational changes by HNE and MDA.

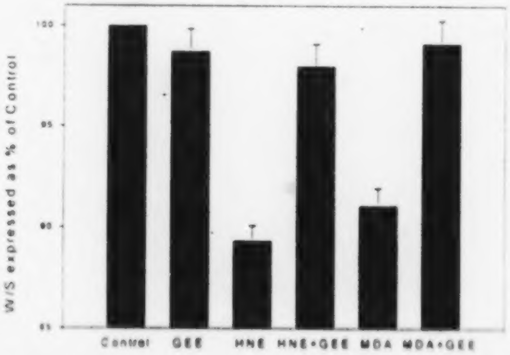

Figure 2: MAL-6 labeled Erythrocytes treated with HNE, MDA, and GEE

DISCUSSION

It is possible that the toxic effects of Aβ peptides are only the first step in the demise of cells in Alzheimer's patients. Products of lipid peroxidation may also contribute to cell dysfunction. Lipid peroxidation products, such as HNE and MDA, are important because HNE and MDA may be strong contributors to the cell damage and death that is characterized in Alzheimer's disease.

HNE and MDA were able to induce significant changes in the measured parameter for protein conformation (*viz.* W/S ratio), at both concentrations, with the percent decrease in W/S ratio being larger at higher concentrations of HNE and MDA. All samples were treated with the vehicle (ethanol) added to the erythrocyte membranes at 5μM and this did not cause any significant change in the W/S ratio of the MAL-6 spectrum. The data are consistent with HNE inducing slower motion of spin labeled proteins, concordant with the hypothesis that HNE can bind to and/or cross-link proteins.

It has been proposed that glutathione protects neurons against HNE and MDA toxicity (9). If HNE- and MDA-induced protein conformational alterations were thought to be important in neurotoxicity, glutathione should modulate the effect on protein conformation caused by HNE or MDA. Erythrocytes were treated with 2 mM glutathione ethyl ester (GEE) for 3 hours and then treated with 50 μM HNE or 50μM MDA. Consistent with the expectation of GEE protection, GEE did protect against the HNE or MDA induced decrease in the W/S ratio of MAL-6 labeled proteins, i.e. prevented the conformational alterations by HNE and MDA.

This study shows that HNE and MDA, at physiological levels, significantly alter the conformation of erythrocyte membrane proteins as assessed by W/S ratio of MAL-6 labeled membrane proteins using EPR spectroscopy. Decreases in W/S ratio observed in dose-response studies of HNE and MDA are due to structural modification or protein cross-linking due to HNE. The reactive sites on HNE (aldehyde functionality, double bond and hydroxy functionality) can cause protein side chains to become conjugated to HNE by Michael addition and cause further cross linking through the e-amino group on the side chain of lysine residues on other protein molecules via formation of a Schiff's base (9). These reactions have been well characterized and it is well known that HNE and MDA can react with cysteine, histidine and lysine residues on protein side chains (9). Modified and/or cross-linked proteins lead to proteins with altered conformation and cause increased protein-protein interactions and are likely explanation for the observed decrease in W/S ratio of MAL-6 labeled erythrocyte membranes treated with HNE or MDA. The production of HNE and MDA during lipid peroxidation occurs within the lipid bilayer. It is reasonable that protein conformational changes reflected by a decrease in W/S ratio would be expected in a membrane undergoing lipid peroxidation.

HNE and MDA are thought to react with glutathione by forming a thio-ether linkage at the double bond, followed by cyclization to a five-membered hemiacetal. The thio-ether linkage is highly stable compared to Schiff's base linkage. Therefore the protection against HNE or MDA induced protein conformational changes afforded by GEE is likely to the inhibition of HNE or MDA reactivity upon forming this cyclic adduct.

The Aβ-associated free radical hypothesis of Alzheimer's disease (4-8,17), suggests that Aβ, the major component of the senile plaques observed in AD brain, is associated with free radicals, which are neurotoxic and cytotoxic (4-8,17). Our laboratory previously established that Aβ-derived free radicals can cause both lipid peroxidation and protein oxidation (5,7,8). Based on these studies a model was proposed to explain the multiple membrane dysfunctions in AD. In a recent study, it has been shown that Aβ can also induce the formation of HNE in hippocampal neuronal cell cultures and synaptosomal membranes (10). That study also further established that HNE or MDA by itself is capable of inducing several of the oxidative-stress responses as that of Aβ, such as disruption of ion-homeostasis and neuronal death (6,10).

Based on this evidence, it is now proposed that even though the generation of free radicals by Aβ will still serve as the first toxic messenger of AD pathology, impairment of protein functions by the lipid peroxidation products HNE or MDA, the second toxic messengers in the cascade, may be of critical significance. This laboratory has shown in a separate study that Aβ can cause structural alterations of membrane proteins in both erythrocyte membranes and brain membranes (data not shown) similar to that observed due to HNE and MDA, and that such alterations in the physical state of the membrane proteins due to Aβ is free radical mediated. HNE or MDA, generated due to the initial free radical insult from Aβ, can subsequently conjugate with various membrane proteins. If generated at high concentrations, HNE or MDA can also lead to alteration in the physical state of lipids, which can affect the function of other transmembrane proteins. The proteins conjugated with HNE or MDA are structurally and functionally modified. Although further work is necessary, these results are consistent with the concept that HNE or MDA could be the ultimate cause of multiple membrane dysfunctions, including Ca^{++} accumulation, observed in AD brain membranes.

Abstract:

Magnesium-aluminum isopropoxide, $Mg[(AlOPr^i)_4]_2$, has been shown to undergo pyrolytic decomposition to produce films of Spinel Proper ($MgAl_2O_4$). The thermal decomposition of $Mg[(AlOPr^i)_4]_2$ was investigated using Evolved Gas Analysis monitored by Fourier Transform Infrared Spectroscopy. Small amounts of isopropanol were evolved from 297-370K as the sample reacted with traces of water in the system. Decomposition began at 665-680K with the production of propene. Propene reached a maximum around 750-755K and then declined. 2-propanone was first observed at 730 to 740K. The amount of acetone produced increased as the temperature was increased. The decomposition followed a Langmuir surface reaction mechanism and has an apparent activation energy of 78.3±8.9 KJ/mol.

Introduction:

Chemical Vapor Deposition (CVD) is used to coat objects from the gaseous phase with a solid of known composition. Recently, interest has developed in devising a process to generate a CVD process that will produce Spinel Proper. Spinel is a mineral that is has excellent thermal, chemical, and shock stability. Current industrial applications center on using spinel as a coating for electronic sensors in extreme environments, such as automobile oxygen sensors.[1] Vacuum pyrolytic decomposition of magnesium-aluminum isopropoxide is promising precursor for forming spinel.[1,2] Meese-Marktscheffel et al.[2] have shown that good quality spinel films can be formed using magnesium-aluminum isopropoxide in CVD processes. However, the mechanism for this thermal decomposition was not established. This study involved an investigation of the thermal decomposition mechanism of magnesium -aluminum isopropoxide. The reaction intermediates, activation energies, and products have been determined for this decomposition.

Experimental:

Apparatus:

The EGA-FTIR apparatus, which has been described in detail previously,[3] was built from a stainless steel four-way cross vacuum flange (MDC Corp.) [fig 1]. Two of the opposing arms were attached to KBr windows with o-ring connectors. One of the remaining arms was connected to vacuum (<100 microns). The other was attached to a 25 cm long piece of 9 mm glass tubing that had been sealed at one end. This tube served as the sample container. Two furnaces were used for this investigation. Each was made by wrapping 12 mm quartz tube with nichrome resistance wire. Power to the variable temperature furnace was supplied using a Perkin-Elmer regulated power supply. Heating rates of 4-8 K/ min were typically used. The constant temperature furnace was powered with a Variac. The temperature of each was monitored via Keithley digital thermometers (±3 K).

IR spectra were obtained using a Nicolet Magna 750 FTIR. This spectrometer scanned a complete IR spectrum (400 - 4000 cm^{-1}) every 2 seconds for reaction times up to 60 minutes. "Chemigrams" of selected IR bands could be made to follow the intensity observed for that species during the decomposition. The Nicolet-Aldrich FTIR library was used to help identify the molecules produced during the decomposition.

Evolved Gas Analysis Procedure:

Tenth to half gram samples of magnesium-aluminum isopropoxide were placed in the sample tube under strict anhydrous conditions and the open end of this tube was coupled to the cell. Two different experiments could be done. In the first, the reaction zone temperature was fixed while the sample zone temperature was increased. This enabled the change in the reaction dynamics as a function of the concentration of the magnesium-aluminum isopropoxide to be determined. In the second, the reaction zone temperature was changed and the sample zone temperature was fixed. This permitted the change of reaction dynamics as a function of temperature to be monitored and enabled the activation energy of each reaction to be determined.

Kinetic Parameters:

Constant Temperature Reaction Zone:

Nearly quantitative conversion of the precursor to product occurred using a hot zone temperature of 773±4K. The rate expression for the chemical reaction B→ P following simple gas phase kinetics is[4]

$$-dB/dt = k[B]^n. \qquad (1)$$

where dB/dt is the change in the pressure of B with time, k is the rate constant, and [B] is the pressure of B at time t. Since the temperature is constant, the k is constant. The flow time through the hot zone, dt, is a function of the pumping speed and is assumed to be constant. Since all of the products (P) are produced during the reaction, dB is proportional to P. Applying Beer's law gives that [P] and is proportional to the absorbance observed for P (A(P)). Applying logarithms gives:

$$-\ln(\text{Abs}) = \ln(k \bullet dt) + n\ln(B). \qquad (2)$$

Using the Clausius-Clapeyron equation[4] of the relationship between the logarithm of the pressure and enthalpy of vaporization to determine ln(B) in equation (2) and combining all constants into a single constant, C, gives:

$$\ln(\text{Abs}) = n(\Delta H_{vap} / R)\,[1/T] + \ln(C). \qquad (3)$$

Therefore, a least squares fit of this linear equation will yield a straight line if the reaction follows simple kinetics and the slope will equal $n\Delta_{vap}H/R$. If $\Delta_{vap}H$ is known, the reaction order is readily determined from this procedure.

Variable Reaction Zone:

The activation energy was found from the variable reaction zone experiments. Rearranging equation (1), taking logarithms of both sides, and using the Arrhenius equation[5] for the temperature dependence of k gives:

$$\ln[\,(dB / dt) / B^n\,] = \ln A_0 - Ea / RT \qquad (4)$$

Since

$$dB / dt \propto -dAbs / dt. \qquad (5)$$

and B^n is proportional to $(1\text{-Abs}/\text{Abs}_{max})^n$ where Abs_{max} is the absorbance observed when the reaction is quantitative,[3] equation (5) becomes:

$$\ln[\text{Abs} / (1-\text{Abs}/\text{Abs}_{max})^n] = \ln CA_0 - Ea/RT \qquad (6)$$

Plotting $\ln[\text{Abs}/(1-\text{Abs}/\text{Abs}_{max})^n]$ vs 1/T will give a straight line with a slope of $-E_a/R$.

Special Handling Techniques:

All compounds were stored and transferred under nitrogen. A rubber septum was used to maintain anhydrous conditions during the transfer of the sample tube from the drybox to

BEST COPY AVAILABLE

the EVA-FTIR apparatus. A glovebag was temporarily attached to the cross vacuum flange to maintain sample purity while the EGA apparatus was evacuated. The sample tubes were scrupulously dried by flash heating with a torch while under vacuum and all tubes were transferred to the drybox while still under vacuum

Results and Discussion:

Evolved Gas Analysis:

Typical IR spectra observed for the decomposition of magnesium-aluminum isopropoxide using variable reaction zone temperatures are presented in figure 2. Decomposition began at 665-680K with the production of propene [fig 3]. The propene production reached a maximum around 750-755K, then declined until data collection was ended. The level of "background" propanol being supplied by the constant temperature source decreased as the propene formed. Shortly after propene production began 2-propanone (acetone) was observed (730-740K). Acetone evolution continued to increase throughout the data collection. Finally, the production of measurable amounts of water was observed beginning at 840K.

Small amounts isopropanol (IPA) were observed from 297-370K in the variable sample zone experiments. The amount of IPA did not increase during the solid to liquid phase change observed at 319 ±3K. However, it increased significantly as the temperature approached the boiling point, 377±3K @ ~100 microns. Peak IPA production occurred between 370 and 430K. A further increase in temperature resulted in rapid sublimation and transport of the starting compound from the sample zone. This quickly exhausted the sample providing an upper limit the experiment.

The IPA evolved during the low temperature range is attributed to hydrolysis of the starting compound by residual water. This can be accounted for by the reaction:

$$MgAl_2(OCH(CH_3)_2)_8 + xH_2O \rightarrow MgAl_2(OCH(CH_3)_2)_{8-x}(OH)_x + xHOCH(CH_3)_2 \quad (7)$$

Further reaction between the hydroxyl moieties in a Sol-gel like process, may account for the viscous residue left in the source zone of the tube.[6] The amount of IPA produced was reduced by special sample handling techniques, but was never completely eliminated.

Propene, the first pyrolysis product evolved, could form via the intramolecular transfer of a methyl proton as shown by:

$$MgAl_2(OCH(CH_3)_2)_8 \rightarrow nCH_3CHCH_2(g) + MgAl_2(OH)_n(OCH(CH_3)_2)_{8-n}(g) \qquad (8)$$

This process could continue until all the alkoxide moieties have been pyrolized, leaving an intermediate species $MgAl_2(OH)_8$. A second possible source of 2-propanone is the catalytic oxidation of IPA by spinel proper. When IPA is passed through a reaction zone coated with spinel from the bimetallic alkoxide, total conversion to acetone and propene can be achieved over the same overall temperature range of the substrate decomposition. A $\Delta_{rxn}H$ was found to be 183±10 kJ/mol for the decomposition. This compares well with values found for Al_2O_3 and MgO which were 171±17 and 177±10 kJ/mol. The Al_2O_3 produced propene from the 2-propanol. The MgO, however, produced acetone from the 2-propanol. This would suggest that the pyrolysis of the alkoxide substrate would favor the conversion of the isopropoxide groups to propene at lower temperatures with a shift towards acetone at higher temperatures. This is observed from the chemigrams for acetone and propene [fig X]. Structurally this is consistent with the alkoxide as the terminal isopropoxide groups are only singly bound by aluminum, which was responsible for propene production. More energy is required for the magnesium to exert catalytic behavior due to the two bonds associated with the bridging alkoxide, hence propene was observed before acetone.

The water observed at higher temperatures could form from pyrolysis of this spinel precursor:

$$MgAl_2(OH)_8 \rightarrow MgAl_2O_4 + 4\ H_2O \qquad (9)$$

Acetone could form from the pyrolysis of the starting material or from a gas phase reaction between the propene and the OH on a spinel precursor such as $MgAl_2(OH)_8$.

$$MgAl_2(OH)_8 + CH_3CH_2CH_2 \rightarrow CH_3COCH_3 + MgAl_2(OH)_6 + H_2 . \qquad (10)$$

Reaction (10) is favored because the acetone was observed in the spectrum after propene, the acetone continued to grow as the propene decreased in intensity after total conversion of the starting material in the variable reaction zone experiments [fig. 4], and a plot of the ln ($A_{2\text{-propanone}}/A_{\text{propene}}$) verses 1/T forms a straight line over the entire temperature range [fig 5]. This relationship is the ideal equilibrium constant for reaction 10. The straight line relationship is consistent with an equilibrium being established between these two species.

The simple gas phase kinetic plots did not give straight lines indicating that reaction does not follow a simple gas phase reaction mechanism. Langmuir rate plots [fig 6] did give the expected linear relationship.[3] However, there was a break in the curve at a pressure of 50 Pa, which may indicate that two mechanisms are occurring. The heat of vaporization was found to be 123±15 KJ/mol from the Langmuir plot.

The apparent activation energy of the decomposition reaction was found using the equations derived for the variable temperature hot zone. Because of the equilibrium between acetone and propene, the absorbances of both major products were used as a sum. The apparent activation energy (E_a) for the alkoxide was found to be 78.3±8.9 KJ/mol.

Synthesis and Characterization:

The synthesis and characterization of magnesium-aluminum isopropoxide followed the procedure given by Meese-Marktscheffel, et *al.*[7] Fifty grams of aluminum isopropoxide (0.244 mol -- Aldrich), 2.97g Magnesium shavings (0.122 mol -- J.T. Baker), and 0.665g Mecurous Chloride catalyst ($1.41{*}10^{-3}$ mol -- Coleman & Bell) were refluxed in 500ml of sodium purified isopropyl alcohol (Aldrich). The reaction was allowed to proceed for at least 96 hours. Shelenk and drybox techniques were observed for all steps. Excess solvent was removed by distillation under passive nitrogen. The product was then isolated and purified using vacuum distillation. A boiling range of 405-407K was observed during the distillation. Solidification of the viscous liquid occurred rapidly upon cooling. Proton, $^{13}C\{^1H\}$, and ^{27}Al NMR were consistent with literature values.

Conclusions:

The thermal decomposition of magnesium-aluminum isopropoxide leads to the surface deposition of Spinel Proper ($MgAl_2O_4$) in a manner consistent with the Langmuir mechanism. The gaseous products that evolved were identified as propene, acetone, propanol, and water. The propene and acetone are observed to be in equilibrium, with the acetone being favored at higher temperatures. The apparent activation energy (E_a) for the pyrolysis of the alkoxide was found to be 78.3±8.9 KJ/mol.

Faculty Advisor
Dr. Thomas C. DeVore

ABSTRACT

The thermal reactions between chlorocarbons that can be used to model the chemical behavior of chlorine containing pesticides and several sodium salts were investigated using Evolved Gas Analysis - Fourier Transform Infrared Spectroscopy. Sodium oxalate was found to react nearly quantitatively with aliphatic chlorocarbons in flow systems at temperatures between 750 K and 900 K. The principle gaseous products were carbon dioxide and traces of carbon monoxide. X-ray diffraction analysis of the black residue confirmed that sodium chloride was present. Since the X-ray pattern did not indicate the presence of graphite, the black color is probably from amorphous carbon. Sodium carbonate also thermally degraded aliphatic chlorocarbons between 600 - 900 K. Chlorobenzene reacted with sodium carbonate at temperatures above 800 K, but the reaction was not quantitative. Sodium hydrogen carbonate did not react with chlorocarbons until the temperatures was well above its decomposition temperature; suggesting that the reaction with sodium carbonate was actually occurring..

INTRODUCTION

Use of chlorine containing pesticides has increased during the past several decades. Pesticides, such as p,p'-DDT have a high stability and tend to accumulate in the environment.[1] Several methods have been devised to destroy the chlorocarbons, but all have some drawbacks. Incineration of the compound in high temperature furnaces is commonly used, but this method is expensive.[2,3] The use of bacteria for soil remediation has merit and may become the method of choice in the future. However, bacteria currently can only break down a few pesticides, which limits the effectiveness of this method.[4] Activated carbon has been used to adsorb pesticides. While this method is effective in removing pesticides from the environment, it offers no possibility of destroying them.

Two lower cost methods have recently been advanced for remediating chlorocarbons. Combustion of chlorocarbons in catalytic furnaces may permit lower temperature operation. Oxide catalysts like U_3O_8 have shown promise in remediating a variety of chlorocarbons and have been suggested as possible systems for waste stream remediation.[2,3] Sodium oxalate has been reported to react quantitatively with fluorochlorocarbons at 550 K in circulating bed systems.[5] This process may also be effective in flow systems under the appropriate conditions. If so, then it could also be used for waste gas clean-up operations during continuous processing. Since alkaline substances are already used in the petroleum industry as HCl scavengers to reduce acidic emissions,[6] they would have the advantage of also removing the HCl produced during the catalytic combustion of chlorocarbons.

The thermodynamics expected for some simple reactions between some sodium salts and tetrachloromethane (CCl_4), trichloromethane ($CHCl_3$), and 1,2-dichloroethane ($C_2H_4Cl_2$) are summarized in Table 1. The reactions for $Na_2C_2O_4$ and Na_2CO_3 have very favorable $\Delta_{Rxn}G(298)$. If initiated, these reactions should be nearly quantitative. It is less certain that $NaHCO_3$ will react as predicted, but reaction via some additional pathway may occur. This investigation was undertaken to determine if the kinetics are also favorable and to determine the conditions where reaction would actually occur rapidly. In addition, reactions with chlorobenzene (C_6H_5Cl) where attempted to determine if these salts would also react with a aromatic chlorocarbons.

EXPERIMENTAL

Reagents

The tetrachloromethane, 1,2-dichloroethane , and chlorobenzene were Fisher ACS. The trichloromethane and the sodium salts were from Mallinckrodt. All chemicals were used as received.

Apparatus

The evolved gas analysis-Fourier transform infrared apparatus used in this investigation has been described in detail previously.[7] Briefly, the IR cell was constructed by attaching KBR windows to two opposing arms of a stainless steel four-way cross vacuum flange (MDC, Inc.) One of the remaining arms was connected to the vacuum line. The other was attached to a 9 mm glass tube that served as the sample container. The open end of this tube was attached to a glass tube that contained the chlorocarbon. A Teflon needle valve was used to regulate the flow of the chlorocarbon into the reaction vessel. A 12 mm Vycor tube, wrapped with Nichrome resistance heating wire, sliped over the sample tube and was used to heat the sample. A Perkin regulated power supply was used to power the furnace. Heating rates of 4- 10 K were used for most experiments. The temperature of the sodium salt bed was measured using a chromel-alumel thermocouple connected to a Keithly Digital Thermometer. The temperature was measured to ± 3 K over the temperature range (298 - 900 K) used.

IR spectra were obtained using a Nicolet Magna -750 FTIR. This spectrometer was set to obtain one spectrum every two seconds for reaction times up to one hour. Spectra were obtained from 4000 to 400 cm^{-1} and could be retrieved for further analysis. The Nicolet-Aldrich spectral library was used to help identify the evolved molecules.

The composition of the residue was determined using powder X-ray analysis. The ASTM x-ray library was used to help identify the components of the mixture.

Procedure

0.1 to 0.5 g of the sodium salt was placed in the center of the reaction tube and held in place with a plug of glass wool. The cell was evacuated, the flow of chlorocarbon was started, and the sample was heated at a slow constant rate. The FTIR was used to monitor the spectrum of the evolved gases as the reaction proceeded.

RESULTS AND DISCUSSION

Samples of the IR spectra obtained as $Na_2C_2O_4$ reacted with CCl_4 are presented in Figure 1. The profile of the species observed as a function of temperature are shown in Figure 2. Nearly quantitative conversion of the CCl_4 was obtained by 750 K if a large excess of $Na_2C_2O_4$ was present. IR product bands arising from CO, CO_2, and C_2Cl_4 were identified in the spectrum. The temperature profile suggested that C_2Cl_4 was a reaction intermediate and that CO_2 was the main gaseous product formed. X-ray analysis of the black residue confirmed the presence of sodium chloride and sodium carbonate. Since these compounds are white and the x-ray analysis did not indicate that graphite was present, the black color probably resulted from amorphous carbon. The carbon, CO_2 and sodium chloride are the products expected from the thermodynamic analysis given in table 1. The C_2Cl_4 was formed from partial reaction of the CCl_4 with $Na_2C_2O_4$

$$2\ Na_2C_2O_4 + 2\ CCl_4 \dashrightarrow 4\ NaCl + C_2Cl_4 + 4\ CO_2 \qquad (1)$$

The C_2Cl_4 then further reacted to give the expected products.

$$2\ Na_2C_2O_4 + C_2Cl_4 \dashrightarrow 4\ NaCl + 2\ C + 4\ CO_2 \qquad (2)$$

Sodium carbonate and CO are also products for the thermal decomposition of $Na_2C_2O_4$[8] and probably resulted from the thermal decomposition of this compound.

$Na_2C_2O_4$ also reacted with trichloromethane and 1,2-dichloroethane in this temperature range. The products observed are summarized in Table 2. These products are consistent with the reactions given in Table 1. No evidence for reaction with chlorophenol was observed. Evidence for the thermal decomposition of the $Na_2C_2O_4$ was obtained in all cases.

Since the x-ray diffraction indicated that Na_2CO_3 was present during the $Na_2C_2O_4$ reactions and the thermodynamic calculations indicated that this compound could also react with the aliphatic chlorocarbons, the reactions between these compounds and Na_2CO_3 were also investigated. The results obtained are summarized in Table 3. With the exception of the 1,2-dichloroethane, the reactions largely occurred as shown in Table 1. The 1,2-dichlorethane reaction was more complicated than anticipated. IR spectrum at 900 K of the reaction products clearly show that vinyl chloride (C_2H_3Cl), ethene (C_2H_4), and ethyne (C_2H_2) were also produced during the reaction. (see Figure 3) The product temperature profiles indicate that CO_2, C_2H_4O, and C_2H_3Cl were formed initially. The CO_2 and C_2H_4O are consistent with the reaction given in Table 1. The C_2H_3Cl must come from a different reaction. While the reaction

$$Na_2CO_3 + 2\,C_2H_4Cl_2 \text{ -------->} 2\,NaCl + CO_2 + H_2O + 2\,C_2H_3Cl \quad (3)$$

has slightly positive $\Delta_{Rxn}H(298)$ (+3.85 kJ/mol), it has a favorable $\Delta_{Rxn}G(298)$ (-95.23 kJ/mol) and is probably forming this compound. The decrease in intensity of the C_2H_4O at higher temperatures corresponded to the increase in the C_2H_4 and the C_2H_2 absorbances. Possible reactions to form these compounds are

$$Na_2CO_3 + C_2H_4Cl_2 \text{ -------->} 2\,NaCl + CO_2 + 1/2\,O_2 + C_2H_4 \quad (4)$$

$$Na_2CO_3 + C_2H_4Cl_2 \text{ -------->} 2\,NaCl + CO_2 + H_2O + 2\,C_2H_2. \quad (5)$$

Both reactions are endothermic ($\Delta_{Rxn}H(298)$= + 96 kJ/mole and + 30 kJ/mol respectively), but have $\Delta_{Rxn}G(298)$ (+24 kJ/mole; - 64 kJ/mol) which indicate that the reaction could become favorable at high temperatures.

While chlorobenzene did not react significantly with chlorobenzene over the temperature range tested, traces of benzene were observed in the spectrum at temperatures over 800 K. Since there was a corresponding increase in the absorbance of the CO_2 and H_2O and a slight decrease in the absorbance of the chlorobenzene in this region, some reaction probably is occurring. The composition of the solid products and the stoichiometry of this reaction have not been established.

Several experiments were attempted to determine if $NaHCO_3$ would also react with these compounds. Although evidence for reaction was obtained, the $NaHCO_3$ had largely thermally decomposed before the reaction with the chlorocarbons began.

CONCLUSIONS

A flow of CCl_4, $CHCl_3$, or $C_2H_4Cl_2$ reacted nearly quantitatively with excess $Na_2C_2O_4$ or Na_2CO_3 at temperatures between 750 K and 900 K. Evolved gas analysis- Fourier transform IR and x-ray diffraction have been used to identify several of the chemical reactions that occurred during each process. Thermodynamic calculations for these reactions indicated that they could provide an alternative to incineration for removing these compounds from waste gas streams, the destruction of freon stockpiles, and remediation of chloropesticide stockpiles. There was also indication that these compounds react with chlorobenzene. However, these reactions are not quantitative in the temperature range investigated and would not be effective for remediation.

ACKNOWLEDGEMENTS:

The Authors are grateful to Cynthia Kerns for assistance with the X-ray analysis and to The ACS - Petroleum Research Fund for supporting this project.

Dr. Beatriz Cardelino

Theoretical studies of several substituted tricyanoquinoline-dimethane molecules have been performed in order to determine their first and second order hyperpolarizabilities. These calculations were performed semiempirically using the finite-field approach. The electron donating and withdrawing substituents added were alkyl, amino and nitro groups, respectively, because of there push-pull effect.

BACKGROUND

The potential for use of certain organic compounds in optical devices such as those found in computers and high density optical recording has lead to increased interest in determining which compounds are best suited for this use. These molecules interact with light in such a way that they are able to affect the frequency, phase or amplitude of the electromagnetic radiation (1). It has been found that large molecules with high third order polarizabilities (γ) show the greatest promise for use as optical switches in such devices. Size requirements prevent the use of ab-initio calculations in determining the third order polarizabilities of these molecules. For this reason, semiempirical methods have been employed to determine the first and second hyperpolarizabilities (β and γ) of substituted tricyanoquinoline-dimethane compounds. These molecules are known to have high third order polarizabilities (2). Using this method the effect of adding electron-donating and withdrawing groups on the hyperpolarizability has been studied. These groups have been added at various positions, separately and in pairs, and the hyperpolarizabilities were determined using the AM1 Hamiltonian .

METHOD

The first step in determining the hyperpolarizabilities was to determine the structure of the molecule with the newly substituted functional groups. Once a suitable initial structure had been obtained, the geometry was optimized using MOPAC (3) and the AM1 Hamiltonian (4) to calculate the structure with lowest bond energy.

The hyperpolarizability (β) is the second-order change of the molecular polarizations (P) which is the result of an applied electrical field (F):

$$P(F)= \mu + \alpha F + \beta F^2 + \gamma F^3 + \ldots \quad (1)$$

where, μ= permanent dipole moment; α= linear polarizability; β= second order polarizability; γ= third order polarizability. Polarization versus static field data were determined semiempirically using a static electric field within the AM1 Hamiltonian. These calculations were performed by the MOPAC program.

The data was analyzed by the HYPER program (5-6) to obtain the hyperpolarizability by the finite-field method. The uncertainties of the polarizabilities where evaluated based on the variability of the coefficients in polynomial expansions of various degrees.

RESULTS

In this research substituents that were electron-withdrawing and electron donating were added to the tricyanoquinoline molecule. From previous unpublished results it was found that the unsubstituted tricyanoquinoline had a $\beta = (653 \pm 47)\times 10^{-51}$ Cm^3V^{-2} and a $\gamma = (197 \pm 10)\times 10^{-61} Cm^4V^{-3}$.

Upon addition of an electron donating group at carbon 6 on ring I(figure 1-I), the β was reduced by 3%. Addition of a symmetrical tertiary amine at carbon 6 on ring I and a nitro group at carbon 3 on ring I (figure 1-III) increased the β by 11 %. Molecule III also demonstrated the greatest third order polarizability (γ), (figure 3) which may indicate a relationship between symmetry on the tertiary substituent and increased γ. The presence of a lone nitro group at carbon 6 (figure 1-IV), produced a β of 789 $10^{-51}Cm^3V^{-2}$, which was greater than the combination of groups in molecule III or the single NH_2 at position 6 in molecule I. It is also 21% greater than the unsubstituted molecule. From the data in figure 3, however, it seems that the electron withdrawing NO_2 group has a negative effect on the third order polarizability where Molecule IV with its lone NO_2 group produced a third order polarizability of nearly half the value for Molecule I with its single amino group.

A correlation between the $\mu\beta$ angle and second order polarizability can be seen in molecules II and IV where second order polarizabilities are greatest for those molecules with the lower $\mu\beta$ angles, which were both lower than 35° (Figure 2). Comparison of dipole moments (μ) and the second order polarizabilities (Table 2) seem to indicate the addition of an electron withdrawing group has a greater influence on the second order polarizability that the electron donating groups. Molecules II, III, and IV with all contain electron withdrawing groups all exhibited greater dipole moments, as well as higher first and second order polarizabilities than Molecule I which lacks an additional electron acceptor.

CONCLUSION

The greatest hyperpolarizability was exhibited by the combination of the asymmetrical tertiary amine at carbon 6 on ring I and the nitro group at carbon 3 on ring I (figure 1-II) which was 85% greater than the unsubstituted molecule. The results seem to show that an increased polarizability can be achieved by the addition of combinations of strong electron acceptors and donors or by a strong electron withdrawing group. Upon comparison of data collected thus far more suitable molecules may be formed which optimize the effect of increased second-order polarizability demonstrated by addition of electron withdrawing substituents and minimize the decreased third order polarizability by using a less electronegative substituent.

Future studies will explore the effect of tertiary amines without opposing electron withdrawing groups, amides and carboxyl groups on the hyperpolarizability of the tricyanoquinoline molecules.

Better Magnetic Resonance Imaging Contrast Agents for Tumor Detection

Leah C. Saunders

Faculty Advisor:

Thomas R. Cundari

Compounds of the metal gadolinium (Gd) are used in commercial magnetic resonance imaging (MRI) contrast agents. Relaxivity is a measure of drug effectiveness with higher relaxivity indicating a better drug. Unfortunately, the link between relaxivity and chemical properties is unclear. This research describes an efficient and accurate semiempirical quantum mechanical (SEQM) method for prediction of the chemical properties of Gd contrast agents. The SEQM method is then used to study possible decomposition pathways for Gd complexes.

BACKGROUND

Drug design is a prime example of the way in which computational chemistry can complement experimental work. Presently, most drugs are first studied with computational methods before undertaking experimental evaluation. Computation allows the medicinal chemist to screen many possible drugs in a very efficient manner, and to focus the experiments on the most promising leads. Computer-aided design of drugs thus has obvious benefits in reduced time and cost. However, this is not yet the case with metal-containing drugs because of the challenges inherent in the application of computational chemistry to metals.

Until recently, little computational research has been done with metals, particularly heavy metals like gadolinium.[1] Traditionally, most computational research has concentrated on organic compounds because of their importance in biology. However, metal-containing compounds are important in medicine and biology. For example, a platinum drug, cis-platin, is the most widely used anti-cancer agent.[2] An example of a metal's importance in biology is the iron-containing protein hemoglobin. The iron plays a pivotal role in respiration.[3]

An important family of metallodrugs is magnetic resonance imaging (MRI) contrast agents.[4] Compounds of the metal gadolinium (Gd) are currently used in all commercial MRI contrast agents. Gadolinium acts as a small magnet and interacts with hydrogen atoms on nearby waters, and this results in a lighter area in the MRI scan of the target tissue and greater contrast. Relaxivity (R_1) is a measure of this magnetic interaction. Higher R_1 indicates a better drug. The advantages of higher relaxivity include faster diagnosis, the need for less agent, and detection of smaller tumors. Unfortunately, the link between relaxivity and chemical properties is currently unclear. Computation could be used to this end, but better methods are needed to realize this goal.

The group of de Andrade et al.[5] have studied europium, the element located next to gadolinium, using computational chemical methods. Metals next to each other in the Periodic Table generally have similar chemical properties. Thus, it is reasonable to inquire whether the method developed by de Andrade et al. for europium can be extended to gadolinium, and hence be used for the study of MRI contrast agents.

HYPOTHESIS

The main goal of this research is to develop an efficient and accurate method for prediction of the geometry of gadolinium contrast agents. Once a computational method for the prediction of geometries is validated it can then be applied to new and existing systems to establish the link between chemical properties (e.g., shape, solubility in water, stability with respect to loss of Gd, etc.) and relaxivity. Being able to predict the three-dimensional geometry of a drug is the first step. The structure of a drug is an important determinant of its pharmacological properties. The present research focuses on the element gadolinium because compounds with this metal are already being used as contrast agents. However, it is desirable to establish a method to isolate compounds that are better contrast agents. The next step, once this is established, is to look at other important contrast agent properties: stability *in vivo*, the viscosity of an aqueous solution of the contrast agent, and the solubility of the drug in water.

Experiments have been conducted in our research group with a family of compounds known as DAP derivatives.[6] One example, GdDAPSC is shown in Figure 1. These compounds have higher relaxivity than current commercial agents and are thus promising for further study. Therefore, we have conducted computational studies to complement ongoing experimental research in our group.

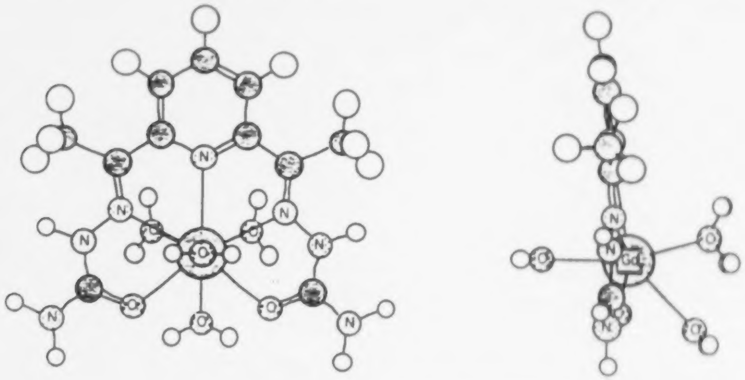

Figure 1: Top and Side Views of [Gd(DAPSC)(OH$_2$)$_4$]$^{3+}$

METHODOLOGY

Computer modeling with heavy metals like gadolinium is substantially more complicated than similar studies on compounds without metals.[7] This research uses methods based on quantum mechanics[1] to predict the geometry of gadolinium based complexes. The simplest molecule, i. e., hydrogen, is depicted in Figure 2. Quantum mechanics describes the energy of a chemical compound as the sum of the repulsions between positively charged nuclei, repulsions between negatively charged electrons, and attractions between the nuclei and electrons. Optimizing the geometry of a contrast agent with quantum mechanics involves finding the positions of the electrons and nuclei which give the most stable configuration. For the hydrogen molecule shown above, this is simple since there are only two nuclei and two electrons. If one considers that a typical contrast agent has dozens of nuclei and hundreds of electrons then it is obvious this is a very large, often intractable, computational problem.

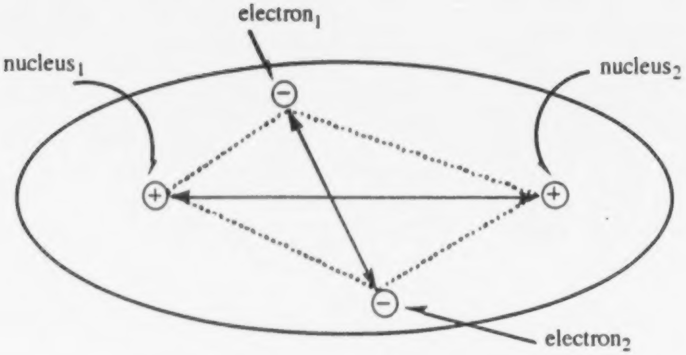

Figure 2: Pictorial Representation of Molecular Hydrogen

The two methods based on quantum mechanics used in chemistry are termed *ab initio* and semiempirical.[1,5] The *ab initio* method is very computationally intensive because all the interactions between nuclei and electrons must be calculated "from scratch." These calculations involve complicated differential equations.[1] The semiempirical approach, however, estimates the most demanding interactions using experimental data. This makes the semiempirical method a much more practical tool than *ab initio* methods for the study of large compounds of the heavy metal gadolinium.[5] As mentioned above, our first task involves extension of the semiempirical quantum mechanical (SEQM) method of de Andrade et al. to gadolinium.

RESULTS AND DISCUSSION

A number of gadolinium complexes have been synthesized in our group.[6] Most of these compounds are derivatives of diacetylpyridine and semicarbazide that are combined to form diacetylpyridinebis(semicarbazide) (DAPSC) by a simple condensation reaction, Figure 3.

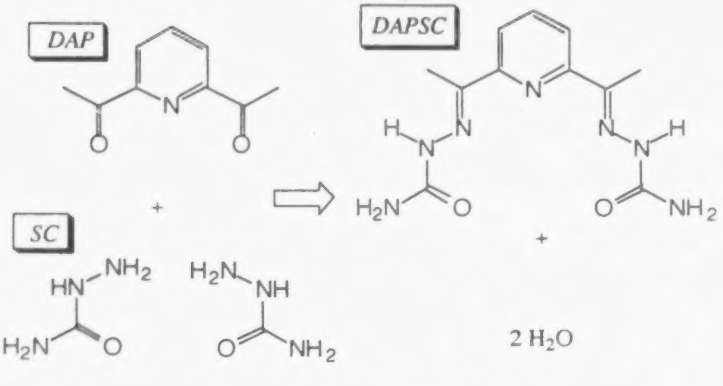

Figure 3: Synthesis of DAPSC Ligand.

DAPSC and related complexes provide an excellent base with which to assess semiempirical quantum methods as computed geometries can be compared to experimental geometries. There are two unitless parameters in the semiempirical method called ALPAM1 and AMAM1.[5] ALPAM1 models the "hardness" of the lanthanide which is inversely proportional to size and directly proportional to formal oxidation state. AMAM1 is a monopole-monopole parameter and is used in estimation of core-core repulsions.

A grid search was conducted changing both ALPAM1 and AMAM1 and observing the effect on predicted geometries. This allows for an "overlay value" to be calculated using the computational and experimental geometries. The overlay is the root-mean-square difference between corresponding atoms in the calculated and experimental structures. Clearly, it is desirable that theory and experiment agree exactly, but in practice this is an unrealistic goal, hence one wishes to change ALPAM1 and AMAM1 until the "overlay value" is minimized. An example of one of these grid searches is shown below in Table 1. Inspection of the data indicates the lowest overlay value for ALPAM1 = 2.0 and AMAM1 = 4.0, and hence best predictive ability for the SEQM method with these parameters. The best overlay is shown in Figure 4 (only heavy atoms are displayed); this agreement is within experimental error. This is just one example of the many DAP derivatives we have studied.

Table 1: Effect of ALPAM1 and AMAM1 on Predicted Geometries

ALPAM1	AMAM1	Overlay
2.0	2.0	0.234
2.0	3.0	0.230
2.0	4.0	0.229
2.5	2.0	0.300
2.5	3.0	0.308
2.5	4.0	0.312

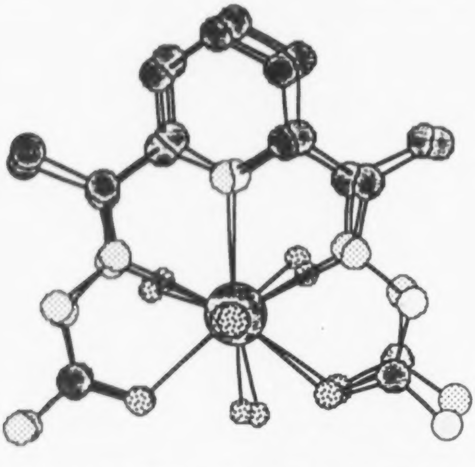

Figure 4: Overlay of SEQM-predicted and Experimental Geometry

Now that the semiempirical quantum method for gadolinium has been validated, computations can be used with confidence. For example, the geometry of DAPSC derived by our SEQM method showed that this compound is fully protonated at the semicarbazide nitrogens. The calculated geometry with protons is in better agreement with experiment than the hypothetical structure without the semicarbazide protons. This point is the subject of controversy since it is difficult to locate hydrogen by experiment.

This is due to hydrogen atoms being very small and hence very difficult to detect, particularly if located near a heavy element like gadolinium. Hence, the computations support the experimental conclusions about the DAPSC complex of Gd,[6a] and provide information not directly available from experiment.

Relaxivity is inversely proportional to the gadolinium-water proton distance. So it is desirable to make this distance as small as possible. When DAPSC is fully protonated it allows the water to be closer to gadolinium. However, if the compound is deprotonated it causes the ligand that is initially neutral to become negative and thus attracted more strongly to the positively charged metal. As the ligand and metal come together, water molecules are "squeezed out." Therefore, the calculations indicate that it is desirable to keep the DAPSC ligand fully protonated. This is an example of the way in which computation can be used to analyze existing systems and identify favorable or unfavorable chemical properties.

Now that an efficient and reliable method has been developed for geometric prediction of potential gadolinium contrast agents, these methods can be applied to the study of new systems. Future research will focus on the DAP motif given the promising results achieved with this system. Of particular interest are DAPSC derivatives where the terminal NH_2 groups have been replaced by other chemical entities. Another future goal is to use calculations to establish the link between chemical properties and relaxivity. For example, under certain experimental conditions it has been shown that the relaxivity is directly proportional to the size of the contrast agent as determined by its total volume.[4,6b] On the other hand, the Gd-water proton distance is inversely proportional to relaxivity. Both the size and Gd-water proton distance can be directly determined from our SEQM calculations. Thus, we can use the SEQM method to modify DAPSC and find derivatives in which these parameters are optimized. In this way the most promising targets are identified for further experiments directed towards better contrast agents for use with magnetic resonance imaging.

ABSTRACT

Many compounds with current biological and industrial applications are aromatic systems. Computational analysis of aromatic molecules can be compared to experimental data obtained via nuclear magnetic resonance (NMR) and infrared (IR) spectroscopy for the electronic effects of aromatic systems. Computational studies were performed on the 2-methoxybenzoic acid system with various substituents to ascertain the interplay between hydrogen bonding, aromatic conjugation, and steric hindrance. The Hartree-Fock self-consistent-field *ab initio* method has been used at the 6-31G* basis level for optimizing the geometries of these systems. Molecular orbitals have been calculated using Spartan 4.1. The results have shown that hydrogen bonding and aromatic resonance are found in the preferred conformation only when the steric strain of the molecule is minimal. Some correlations have been found between computational and experimental results.

INTRODUCTION

The 2-methoxybenzoic acid system has been studied with respect to hydrogen bonding and aromatic resonance as these electronic effects change with steric substitutions. The importance of both intramolecular and intermolecular hydrogen bonding is widespread in the biological sciences as well as in the polymer industry. Hydrogen bonding is essential for nucleotide interactions in DNA (deoxyribonucleic acid), amino acid structural interactions in proteins, and catalytic interactions in enzymatic proteins. Understanding the stability of the hydrogen bond and its contribution to the overall energy of a system are important to understanding the role hydrogen bonds play in larger systems.

The molecular orbital describing the conjugation of a substituent on an aromatic system is a combination of p-orbitals overlapping with π-symmetry as shown in figure 1. This assumes that the π-system is completely described by one molecular orbital. This may not be the case when the orbitals contain different types of atoms.

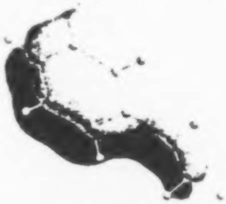

Figure 1: π-Ring System and Substituent (Phenylethene)

Another issue involving π-conjugation is the added stabilization of the molecules's geometry due to resonance with the ring. A comparison of this resonance stabilization with the stabilization due to hydrogen bonding and the opposing forces of steric hindrance allows for an assessment of the driving force in attaining the optimal geometry. The 2-methoxybenzoic acid (MBA) system used for this analysis (see figure 2) provides both a rigid framework which juxtaposes sterically hindered substituents and also resonance stabilization for the carboxylic acid and methoxy substituents.

The theoretical calculations have been compared with nuclear magnetic resonance (NMR) and infrared (IR) spectroscopy findings. They provide an experimental measure of the percent of hydrogen bonding for 3-R,2-methoxybenzoic acid (MBA-R) where R is a variety of substituents. The fraction of all possible geometric conformations that are hydrogen bonding can be compared to the computational values for the relative stability and strength of hydrogen bonding in the important conformations for each molecule.

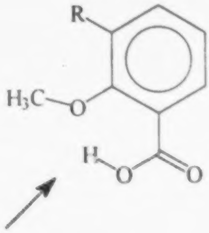

Figure 2: Top View of 3-R,2-methoxybenzoic acid (MBA-R [H,TA])
(The arrow indicates the hydrogen bonding distance.)

METHODS

Hartree-Fock self-consistent-field *ab initio* calculations at the 6-31G* basis level using Gaussian 94 provide geometry values which correlate well with experiment. Energy values obtained using this basis set are reasonable for approximating experimental values when the energy differences between molecules are compared.[1] The molecular orbital images obtained using Spartan 4.1 are calculated from the ab initio wavefunction at 6-31G* which provides a good approximation of electronic properties.[2]

DISCUSSION

Hydrogen Bonding Stabilization of Geometry

The conformation of each molecule where hydrogen bonding occurs is the trans acid (TA) form where the carboxyl group is oriented with its hydroxyl closest to the carbon-2 methoxy (this is the [H,TA] case). In the unsubstituted molecule (MBA-H), a distance of 1.806 Å is found for the hydrogen bond. Hydrogen bonding distances (see figure 2 and table 3) increase when different substituents are added at carbon-3. The length of the hydrogen bonding distance increases as the experimental fraction of hydrogen bonding decreases,[3] so both computational and experimental data suggest that hydrogen bonding strength decreases with steric substitution.

Steric hindrance caused by a substituent at carbon-3 reduces the effectiveness of the hydrogen bond. This steric effect is minimal in the MBA-H and MBA-OCH$_3$ cases. There is some compensation for steric strain as seen in changes in the dihedral angle of the carboxylic acid with the ring ("DiheAcidPlane" in table 3). The increase in the total energy for MBA-H and MBA-OCH$_3$ between the trans, [H,TA], and cis, [H,CA], cases (see table 3) demonstrates the stabilization provided by the formation of the hydrogen bond in the trans case. In the MBA-OCH$_3$ case, where the increase in energy from [H,TA] to [H,CA] is the greatest, the "Steric R-MeO" distance is the largest. This shows that the carbon-3 methoxy can move away from the carbon-2 methoxy such that steric hindrance is minimized and hydrogen bonding is favored.

The MBA-CH$_3$ and MBA-Naph (Naphthalene) cases show a decrease in energy for the [O,CA] and the [H,CA] cases compared with the hydrogen bonding case which is likely due to a relaxation of the methoxy away from the carbon-3 substituent once the disruption of hydrogen bonding allows easier movement of the methoxy group. Data from the simple formic and acetic acid systems also provide some explanation for this stabilization of the [CA] form. As shown in table 3, the change in energy between the [TA] and [CA] forms of both acids show that the [CA] form is lower in energy since no hydrogen bonding can occur. If the hydrogen bond stabilization is decreased due to the carbon-2 methoxy orientation, as in MBA-CH$_3$ and MBA-Naph, then the favored [CA] form overpowers the hydrogen bonding stabilization.

The Hartree-Fock energy values were converted to the percent of molecules in each occupied conformational state using statistical mechanics. The computational results show that the most populated conformational state of MBA-H and MBA-OCH_3 is the [H,TA] hydrogen bonding case with 74% and 59% hydrogen bonding, respectively. However, for MBA-CH_3 and MBA-Naph, the hydrogen bonding state contained only 13% and 7% of the molecules. The predominant conformation for these two cases is the [O,CA] case where the preference for the cis acid predominates due to greater steric strain. The [O,CA] state occupies 68% of the molecules in each case. When compared with NMR and IR data, these percents correlate roughly with experimental data. Certain discrepancies do exist between experiment and computation which have prompted detailed studies into these variations.

Table 3: 6-31G* Optimized Geometry and Energy Values for Formic Acid, Acetic Acid, and Substituted Benzoic Acid Derivatives

Abbreviations: ΔRHF(E) = Change in Restricted Hartree-Fock Energy in kJ/mole with respect to the reference value (all frequencies are positive), H-BondDist = distance (Å) between the carboxyl hydrogen and the methoxy oxygen, Steric R-MeO = the distance (Å) between the nearest hydrogens of the methoxy and the R-group, DiheAcidPlane = dihedral angle between the carboxylic acid and the ring plane, DiheCOOH = dihedral angle within the carboxylic acid substituent, Dihe MeO = dihedral angle of the methoxy acid to the ring plane, [,] = geometric conformation specification, H = Hydrogen of carboxyl group facing methoxy, O = carbonyl oxygen of carboxyl group facing methoxy.

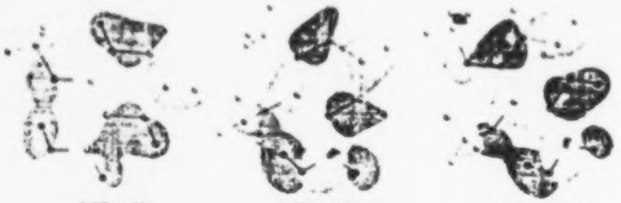
Molecular orbitals have been found in each case which clearly show the hydrogen bonding between the carboxyl hydrogen and the methoxy oxygen. Even when the hydrogen bonding conformation is not the most energetically favorable, a molecular orbital showing hydrogen bonding can be found for each substituted 2-methoxybenzoic acid. Three of these orbitals are shown in figure 4.



MBA-H MBA-CH_3 MBA-OCH_3

Figure 4: Hydrogen Bonding Molecular Orbitals (H, TA conformations)
(See figure 2 where the arrow indicates the location of hydrogen bonding.)

Resonance Stabilization of π-Substituents

Resonance of substituents to the aromatic system is displayed by the preference of these substituents to lie in the plane of the ring unless steric forces do not permit such a conformation. For the MBA-H cases shown in figure 5, the methoxy and the acid lie completely in plane with the ring (The numerical dihedral angles can be found in table 3 in the "Dihe MeO" and "DiheAcidPlane" columns.). The presence of the methyl group on carbon-3 in MBA-CH_3 does not allow the methoxy to lie flat. In the [H,TA] case, a small displacement of the carboxyl out of the ring plane can be seen which allows the acid to hydrogen bond with the 90 degree methoxy. Oxygen-oxygen repulsion in the [O,TA] and [O,CA] cases also disrupts the resonance of the carboxyl group with the ring. The 100 degree dihedral angle of the carbon-2 methoxy in the MBA-OCH_3 case allows hydrogen bonding in the [H,TA] case, but actually causes oxygen-oxygen repulsion in the [H,CA] case in addition to both [O] cases. However, resonance of the methoxy oxygen lone pairs and the carboxylic acid group with the ring is still evident even with some distortion from the ring plane.

Figure 5: Planar Nature of Methoxy and Carboxylic Acid Substituents
Side View of 3-R,2-methoxybenzoic acid. (Arrow in figure 2 shows line of sight)

Molecular orbitals of the MBA-H [H,TA] system (see figure 6) show the π-systems in resonance with the aromatic ring. The various π-systems appear in molecular orbitals of different energies in contrast with the prediction of one conjugated π-orbital as shown in figure 1. The ring carbons appear in the π-orbital of highest energy with the carboxylic acid and carbon-2 methoxy π-orbitals following in decreasing energy. This separation into different molecular orbitals may be due to the formation of lower energy molecular orbitals when oxygen atomic orbitals are involved.

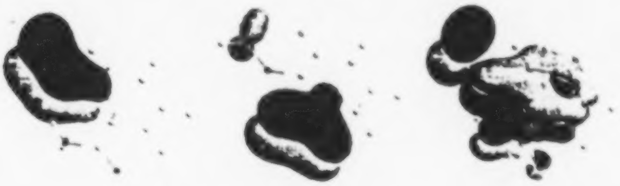

Figure 6: π-Conjugation of MBA-H [H,TA].
MO# 25 (π-System Conjugation Extending to Carbon-2 Methoxy), MO# 29 (Acid Conjugation), MO# 33 (Aromatic Ring π-System)

CONCLUSIONS

The driving force for the lowest energy conformation of these aromatic systems is the resonance of π-substituents with the aromatic ring. Aromatic resonance controls both the orientation of substituents and the stabilization of each conformation due to π-conjugation. Hydrogen bonding lowers the overall energy of a system once the components are properly aligned. Unless the steric strain becomes too great, with or without hydrogen bonding, the substituents prefer to remain in plane with the aromatic ring.

Future studies will attempt to understand discrepancies between experimental and computational percent hydrogen bonding values. The MBA-NO_2 and MBA-t-butyl cases will also be investigated.

Kate J. Graham, Ph. D.

Candida albicans is a dimorphic, pathogenic fungus. In fact, pathogenicity in *C. albicans* appears to be linked to its ability to switch rapidly between morphological forms. Therefore, an understanding of the biochemical regulation may prove useful in understanding pathogenicity and the design of new antifungal drugs. A bioassay was developed to follow the growth modulating activity. An extracellular, organic compound was found to exhibit biological activity in the morphological control of dimorphism in *Candida albicans* and has been partially purified through bioassay-guided fractionation. Further work on the purification and identification of the active component is being conducted.

INTRODUCTION

Candida albicans, a dimorphic fungus, is the most widely studied human fungal pathogen. *Candida albicans* is a fungus which can exist in two principal cellular forms: as yeast cells (single celled) or as mycelia (filamentous cell chains).[1] Reversion refers to *C. albicans* ability to switch between the two morphological phases. Many environmental variables such as temperature, gaseous environment and cations are known to effect the morphology of *C. albicans*,[1] but the molecular mechanism for the control of reversion has not yet been identified.

In the industrial setting, the yeast phase is preferred because growth rates of fungi are maximized in this form due to the increased surface area.[2] Yeasts are also much easier to handle mechanically in the stirring and filtering processes. The isolation of an organic chemical that controls the morphology of fungi during changing environmental conditions will be of tremendous use to industry.

In addition, a common feature of the majority of human pathogenic fungi is that they exhibit dimorphism and it is common to find that the morphology of the fungus in the infected tissue is different from that of the initial infectious agent.[3] Topical infections involving *C. albicans* are common, but systemic candidiasis is seen primarily in immunocompromised individuals. Systemic candidiasis refers to cases where *Candida* is found in the bloodstream with or without tissue invasion or to disseminated disease where single or multiple organs are sites of infection.[4] The limited number of safe, effective antifungal drugs and a growing number of resistant strains of yeast exacerbates these problems.[5]

The ability of *C. albicans* to alter its phenotype rapidly appears to allow the fungus to adapt to different host environments.[6] There is solid evidence that hyphae production is an essential factor in pathogenicity; hyphae are able to resist phagocytosis and are able to adhere and penetrate through host epithelial layers.[3,4,7] Experimentally, it has been observed that hyphae are present in most lesions and yeast cells inoculated into animals rapidly develop hyphae.[3] Since *Candida* appears to be a more effective pathogen due to mycelial formation, an understanding of the biochemical regulation would be helpful in the design of new antifungal drugs.

Previous studies indicate that regulatory control of fungal morphology is dependent upon population density.[8] It is well known that, at specific population densities, many types of bacteria will secrete autoinducers that control bacterial growth and differentiation.[9] Preliminary data from this project indicated some compound(s) present in the broth of the dimorphic fungus, *Candida albicans*, can trigger a dimorphic switch. These data suggest the biochemical control system of fungal morphology is initiated by an extracellular signal as in the bacterial systems whereas previous research on dimorphic fungi has investigated only the potential of intracellular mechanisms. Isolation of an organic compound responsible for regulating the dimorphic transition would significantly add to the understanding of this complex phenomenon.

RESULTS AND DISCUSSION

As the background of this research involved microbiology, this research was conducted in collaboration with Dr. Ellen Jensen, a microbiologist in the Biology Department at The College of St. Benedict/St. John's University.

Candida albicans, strain A-72, was grown in GPP (Glucose Proline Phosphate) growth media. Under these conditions, the morphology of the fungus can be controlled by the temperature at which the cells are incubated.[10] Cells grown at room temperature (RT) grow as yeast while those cells incubated at 37°C grow as mycelia. To detect an extracellular regulating compound, the media from either the yeast or the mycelial cells were extracted with EtOAc and concentrated. Yeast or mycelial cell cultures were then treated with concentrates and the cultures were then tested for reversion. In cultures treated with RT broth, but grown at 37°C, 84% of the cells grew as yeast. Thus, a compound in the RT broth either inhibited mycelial growth or promoted yeast morphology.

35 L of RT broth from *C. albicans* in GPP media was grown, centrifuged and then filter-sterilized. The organics were extracted from the aqueous portion with EtOAc and the organic fraction was concentrated. The organic fraction demonstrated activity when tested in the bioassay. A Modified Kupchan extraction was used as a procedure to fractionate the crude extract on the basis of polarity. The fractions were tested for activity with the reversion assay. 88% reversion was obtained from both the hexane and chloroform fractions. The combined active fraction was further purified on a 75g Sephadex LH-20 column with 1:1 MeOH/CH_2Cl_2 as the eluent. 5 mL fractions were collected and eluted on silica TLC plates. R_f values were used to combine the tubes into fractions which were subsequently assayed. Fraction 3 (tubes 36-39) contained the majority of the activity and promoted 91% reversion to yeast.

This research represents the partial purification of an extracellular signal for biochemical regulation of dimorphism. Continuation of this project will require HPLC to isolate the active growth regulating compound in *Candida albicans*. Upon obtaining a pure compound, structural determination will be performed with analytical tools such as 1-D and 2-D NMR techniques, IR, UV, MS and X-ray crystallography.

EXPERIMENTAL

Culturing *Candida albicans*. *Candida albicans* (strain A-72 from culture collection of K. W. Nickerson) was inoculated in 500 mL Erlenmeyer flasks containing 100 mL of growth media [80 mL .05 M PO_4 buffer (pH 6.0); 0.03 mL vitamin mix (20 µg biotin, 100 µg pyridoxin and 200 µg dissolved in 10 ml of 50:50 H_2O/EtOH) and 0.10 mL mineral mix (0.38 g. $ZnSO_4{*}7H_20$, 0.38 g $MnCl_2{*}4H_2O$, 0.38 g $CuSO_4{*}5H_2O$ and 0.38 g $FeCl_3$ dissolved in 75 mL .1 N HCl); 10 mL 20% dextrose solution; and 10 mL 0.1 M Proline solution]. The buffer and the minerals and vitamins were autoclaved. The proline and dextrose solutions were autoclaved at 121°C and 15 psi for 15 min. separately. After cooling to room temperature, the proline and dextrose solutions were added to the buffer solution. This growth media was inoculated at an initial concentration of $1{*}10^7$ cells/mL. The flask cultures were incubated at RT (yeast phase) or 37°C (mycelial growth) and aerated by agitation at 150 rpm for 24 hrs.

Biological Assay. 0.3 mg of the dried organic fractions were dissolved in the appropriate solvent and transferred to 25 mL sterile Erlenmeyer flasks. . The flasks were placed in a laminar flow hood until the solvent had evaporated. 5.0 mL of media was added to the flasks (0 .5 mL 0.5 M $P0_4$ buffer, 0.5 mL 20% glucose +vitamins + $MgSO_4$, .13 mL 0.1 M N-acetylglucosamine, .17 ml 0.3 M proline, 3.7 mL of H_2O) and was then inoculated to give an initial concentration of

1 E+7 cells/ml. The cells were incubated at 37°C and 150 rpm. Under normal conditions, four hours provides enough time so that at least 90% of the cells will form germ tubes. After four hours, a 20 µl sample of the media was placed on a slide and covered with a cover slip. 100 cells were counted at two different locations and the average number of cell types (hyphae or single cells) were tabulated.

Purification of the Extracellular Compound. After culturing *C. albicans* for 24 hrs at RT, the cells were centrifuged for 30 min. at 6000 rpm and 6°C. The broth was decanted off and then filter-sterilized. Each 500 mL of filtrate was extracted with 3 x 200 mL portions of EtOAc. The organic extract was dried over $MgSO_4$, filtered and concentrated. The remaining crude extract (315 mg) showed 84% reversion of mycelium to yeast. As a control, the growth media was also extracted in a similar manner and was found to have no activity. The crude extract was initially purified with a Modified Kupchan extraction using Hexane, $CHCl_3$, CH_2Cl_2, and EtOAc successively and increasing the H_2O/MeOH ratio after each solvent. 88% reversion was shown in the Hex and $CHCl_3$ fractions (154 mg) which were then eluted on a 75 g Sephadex LH-20 column with 1:1 MeOH/CH_2Cl_2 as the eluent. Each 5 mL fraction from the column was spotted on Kodak Chromagram Silica TLC plates with Fluorescent Indicator and eluted with 95:5 chloroform/methanol. The plates were visualized with UV, iodine, and phosphomolybdic acid in 95% ethanol, successively. The R_f values were used to combine fractions. The fractions were assayed and activity (91% reversion) was located in the fraction containing tubes 36-39 (21.3 mg). Future work on the purification and identification of the active component will be conducted.

Dilip K Paul

Both physical and chemical adsorption behavior of CO and NO on Pd/Al_2O_3 catalysts were studied using *in situ* FT-IR and mass spectroscopy A specially designed IR cell is used for this purpose where the effect of both support and metal can be simultaneously monitored Different metal loadings show strikingly different NO adsorption behavior For example, the formation of N_2O was at a maximum for 2 2% Pd, and at a minimum for 10% Pd/Al_2O_3 This behavior is consistent with the idea of having different CO adsorption energy for particles with different sizes. Furthermore, the coadsorption behavior of CO and NO indicates the formation of isocyanate species at elevated temperatures for surfaces with different metal loadings

INTRODUCTION

Recently there has been considerable interest in using only palladium as an active component for automotive exhaust gas conversion Many ultra-high vacuum (UHV) studies have focused on the nature of CO and NO chemisorption on low index planes of palladium (Chen and Goodman, 1993) The objectives of these studies were to identify the CO/NO reaction products and kinetics over polycrystalline palladium surfaces However, a few studies have examined the reactions at low temperature for different metal loadings on Pd/Al_2O_3 catalysts

In order to better understand the mechanisms of the CO/NO reaction, it is essential to identify the adsorption sites and surface coverages of the reactants Although some studies have been done to elucidate the structures of adsorbed CO and NO separately, on supported palladium above room temperature (Valden *et al*, 1996) Few studies have looked at the adsorption of NO and coadsorption of CO/NO at low temperatures

The aim of this paper is to characterize the surface reaction processes of NO, CO, and NO/CO on Pd/Al_2O_3 under different catalytic conditions using FT-IR and mass spectrometry

EXPERIMENTAL

Al_2O_3 - supported Pd catalyst samples of different metal loadings were prepared in a slurry containing $PdCl_2$ and Al_2O_3 (Degussa aluminum oxide C) in the appropriate ratio The slurry was suspended in a liquid consisting of nine parts spectroscopic grade acetone and one part distilled water The slurry was deposited by spraying through an atomizer onto one-half of a 25-mm-diameter CaF_2 disk maintained by a hot plate at 340 K The solvents evaporated rapidly, leaving a thin adherent film of $PdCl_2/Al_2O_3$ on the support disk A second sample of blank Al_2O_3 support was prepared in the same manner and deposited on the other half of the disk This method of using two different catalytic films for IR and mass spectroscopic study allow us to observe any chemistry occurring on the support itself which has been treated under identical conditions as the catalyst

The catalyst sample was then mounted inside the stainless steel ultrahigh vacuum infrared cell designed by Yates and co-workers (Beebe, Gelin, and Yates, 1984; Beebe and Yates, 1985) This cell consists of a main cell body (double-sided conflat flange) containing a CaF_2 disk that serves as the sample holder, held in place by a Cu support ring which may be cooled by $N_{2(g)}$ and heated by heating tapes The cell body is contained between two CaF_2 windows sealed in stainless steel conflat flanges, permitting IR measurements in the 4000-1000 cm^{-1} spectral range The infrared cell is attached to a bakeable stainless steel gas handling system and is typically maintained at a base pressure of $P < 1 \times 10^{-8}$ Torr Pumping is carried out by a 50 L/s turbo molecular pump (Balzers)

15

The sample is then outgassed under vacuum at 475 K for about 12 h and subjected to 15, 30, 45 and 60 min cycles of exposure to ~ 400 Torr of H_2 at 475 K, each cycle being terminated by evacuation to 1 x 10^{-6} Torr. The reduced samples were allowed to remain under vacuum (< 1 x 10^{-6} Torr) at 475 K for ~ 8 h. For low temperature reactions, background scans were taken of the unreacted sample as it was cooled to 110 K at 20 K intervals.

The reagents used in this study, CO (99.99% purity, Matheson Gas Products, Inc.), NO (98.5% purity, Aldrich Chemical Company), and H_2 (Research Grade) were all obtained in high-pressure cylinders, and were used without further purification.

Infrared spectra were measured by use of a purged Mattson RS-1 FTIR spectrophotometer interfaced with a personal computer for data storage and manipulation. The spectra presented here were obtained with 500 scans at a resolution of 4.0 cm^{-1}. Mass spectral data of the gases were collected by introducing gases to the quadrupole mass spectrometer using a high precision leak valve during adsorption experiments.

RESULTS AND DISCUSSION

Low Temperature Adsorption of NO on Pd/Al_2O_3

Figure 1 indicates the IR spectral behavior upon sequential exposure of NO on 0.5% Pd/Al_2O_3 at 110 K. Two sets of IR bands corresponding to ν(N-O) modes (one at 1874 and 1761 and the other at 1901 and 1815 cm^{-1}) gradually developed on Pd/Al_2O_3 along with an IR feature at 2245 cm^{-1}. On the other hand, only one set of bands at 1876 and 1741 cm^{-1} are observed (not shown) along with a small shoulder at ~ 1810 cm^{-1} on blank Al_2O_3 surface. The formation of NO surface species caused the decrease in the intensity of isolated hydroxyl groups on Al_2O_3 indicating the presence of H-bonded nitrosyl groups on surfaces. Upon warming, these bands disappear on 0.5% Pd/Al_2O_3 (Figure 2) with gradual formation of the 2245 cm^{-1} feature (Valden *et al.* 1996). The band at 2245 cm^{-1} can be assigned to ν_{as} (N-N-O) for physisorbed N_2O gas. This weakly bound species desorbs at ~230 K indicating its gas phase rotational P, Q, and R modes centered at 2223 cm^{-1}.

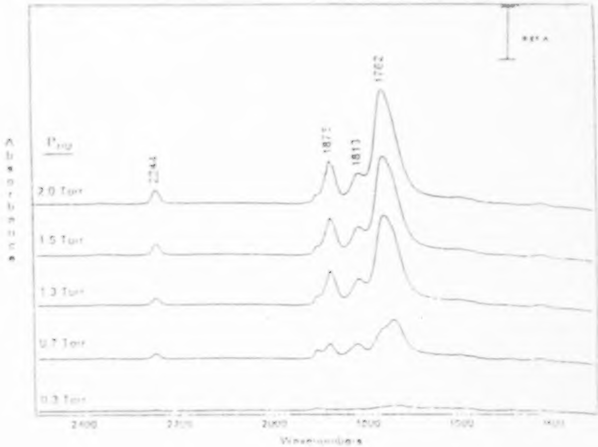

Figure 1. Infrared spectra for the sequential exposure of NO on prereduced 0.5 % Pd/Al_2O_3 at 110 K.

Assignment of Surface Species

The IR bands at 1901, 1815, and 1761 cm^{-1} may be tentatively assigned to $Pd\text{-}NO^+$ and Pd-NO, and $Pd\text{-}NO^-$ surface species respectively (Arai and Tominaga, 1975). These assignments are consistent with the studies on Rh/Al_2O_3 surface. However, the band at 1874 cm^{-1} could be due to weakly adsorbed ν(NO) mode on Al_2O_3 support. Nitric oxide can be easily oxidized into a nitrosonium ion NO^+ by donation of one electron from its antibonding orbital to the metal. A coordination of $Pd\text{-}NO^+$ is formed by an additional electron pair donation from NO^+. When ν(NO)

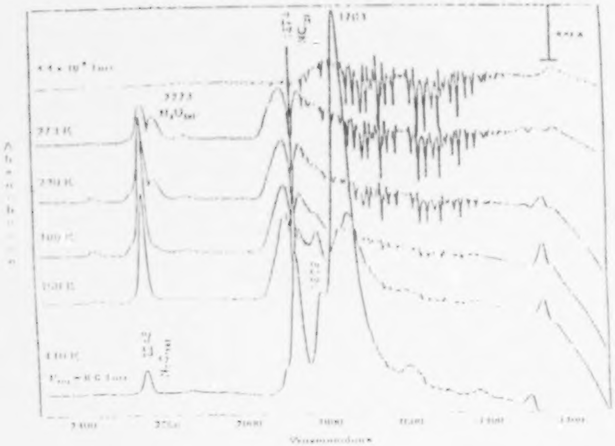

Figure 2. Infrared spectra for the exposure of NO on prereduced 0.5 % Pd/Al_2O_3 as a function of temperature.

is much lower than that of gaseous NO molecule (1876 cm^{-1}), the nitric oxide is assigned to the structure of NO^-. The frequency of $\nu(NO)$ is dependent upon the extent of donation of an electron from π^*_{NO} to the palladium d-orbital

Low Temperature N_2O Formation

The formation of N_2O was determined by measuring the integrated absorbance of 2245 cm^{-1} as a function Pd loading, temperature, and pressures of NO. The dependence on loading, temperature, and pressure is given in Figures 3, 4, and 5. The N_2O formation gradually increases with Pd loading up to 2.2 %, and then decreases dramatically for 10 % Pd. In order to understand the volcanic type behavior for N_2O formation as a function of Pd loading, it is important to focus on the fundamental aspect of the mechanism of N_2O formation at low temperature. The earlier studies suggests that the N_2O formation takes place according to two mechanisms a) breakdown of dinitrosyl species and b) dissociative adsorption (Hierl, Urbach, and Knozinger, 1992). At low temperature the energy required is not available for dissociative adsorption of NO, which can be ruled out. The breakdown of dinitrosyl species forming N_2O is not as energy intensive as the dissociative adsorption of NO. Although the formation of dinitrosyl complexes is not detected in the present low temperature study, its formation cannot be ruled out. The formation of N_2O depends on several factors: oxidation state and size of the metal particle in addition to dispersion of the active metal. The work is in progress to answer these critical questions.

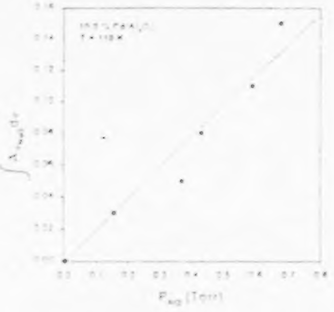

Figure 5 Formation of physisorbed N_2O as a function of pressure during exposure to NO at 110 K.

High Temperature Interaction of NO/CO

Figure 6 shows sequential IR studies of the NO/CO reaction on 0 5 % Pd/Al_2O_3 as a function of temperature Initially, upon NO/CO coadsorption the nitrosyl bands observed at 1817 and 1755 cm^{-1} in addition to very weak bands at 2134 and 2090 cm^{-1} due to adsorbed CO These linearly bound nitrosyl complexes disappeared at 460 K giving rise to nitrite and nitrato complex formation on alumina which was observed at 1600-1200 cm^{-1} Typical absorption bands were observed at 1618, 1560, 1457, and 1270 cm^{-1} The formation of CO_2 and N_2O gases are also observed at 2354 and 2220 cm^{-1} by using both FT-IR and mass spectroscopy The formation of an absorption band at 1612 cm^{-1} is probably caused by NO_2 The infrared bands of adsorbed NO_2 are normally observed at 1618, 1318, and 750 cm^{-1} (Valden *et al*, 1996) Adsorbed NO_2 species can be formed when gaseous NO reacts with oxygen bonded to Pd and created by the dissociation of NO Upon evacuation at room temperature, a strong band at 2265 cm^{-1} corresponding to ν_{as}(NCO) mode appeared indicationg the formation of iscocyanate species (Paul and Worley, 1990) Thus, NO and CO react on the surface to form N_2, N_2O, CO_2, adsorbed isocyanate, and nitrito and nitrato species

CONCLUSIONS

The following conclusions can be drawn from this work

(1) Formation of N_2O is observed at low temperature (110-278 K) as well as at high temperature and its production is maximum for 2 2 % Pd/Al_2O_3 This observation may be related to the size of Pd particles The development of the IR peak at 2245 cm^{-1}, which corresponds to N_2O physisorbed species, also depends on the NO coverage

In this project, two-dimensional NMR techniques were utilized to study the following nucleotide:

CGCGCTTTCGCGC
GCGCGAAAGCGCG

A modified version of the sequence, in which the central adenine was replaced by 5-nitroindole, was also studied. Partial proton assignment was accomplished using TOCSY. However, many peaks were ambiguous. NOESY and COSY experiments were used to resolve these peaks. Complete proton assignment was accomplished for the thymidine core, using these experiments. One-dimensional NMR spectra revealed that the modified oligonucleotide is less stable than the modified.

INTRODUCTION

Oligonucleotides are small segments of DNA (deoxyribonucleic acid) that can be modified by substituting one or more of the naturally occurring nucleotide bases with a "universal base". A "universal base" is one which can pair with each of the natural bases indiscriminately. In recent years, these modified oligonucleotides have become the subject of intense research for use in gene regulation and in studies of DNA and RNA (ribonucleic acid) activity. Modification of the oligomer is beneficial especially when base pairing with a target nucleic acid whose sequence is unknown. Ideally, a universal base would pair with high affinity to any of the naturally occurring DNA bases and form a stable duplex. The stability of the oligomer, containing the modified base, is determined by its structure. One common technique for determining the structure is multi-dimensional nuclear magnetic resonance (NMR).

NMR is currently the most powerful tool for determining the structure of organic molecules. Only nuclei with an odd mass number have a "nuclear spin". When these nuclei are subjected to the right combination of magnetic field and electromagnetic radiation, they will absorb the radiant energy. The absorption of radiant energy results in a reversal of their nuclear spins. The amount of energy absorbed is represented by the NMR spectrum. The location of the absorption peak in the spectrum depends on the chemical environment surrounding the nucleus. The environments of the various nuclei found in oligonucleotides are chemically diverse. This results in extremely complicated spectra. In order to obtain useful information about the structure, multi-dimensional NMR techniques are employed. Two-dimensional NMR works essentially the same as one-dimensional methods, except it spreads the interactions between the nuclei into a second dimension. Thus it clarifies the resulting spectra. Three types of NMR spectroscopy were used to detect these interactions: TOCSY (TOtal Correlated SpectroscopY), NOESY (Nuclear Overhause Effect SpectroscopY), and COSY (Correlated SpectroscopY). TOCSY, the main type of NMR spectroscopy used on this project, can detect interactions occurring between nuclei that are several atoms away. COSY detected the interactions of nuclei up to three bonds away and NOESY detected the through-space interactions of nuclei. The COSY and NOESY spectra were used to support results found in the TOCSY spectra and to remove ambiguities.

METHODS AND PROCEDURES

The oligonucleotides were synthesized on an ABI (Advanced Bioscience) DNA synthesizer using standard phosphoramidite chemistry and purified by HPLC (high performance liquid chromatography). The samples were solvated in D_2O for NMR sampling. Traditional one-dimensional spectra, as well as two-dimensional COSY, NOESY, and TOCSY spectra were obtained using a 600 MHz Varian NMR Spectrometer at the University of Akron's Chemical Instrumentation Center.

Backbone Proton Assignments

Initial proton assignments were made based on TOCSY experiments. Protons were assigned using the reported proton ranges (Brown) listed in Table 1 and the observed connectivities. The backbone protons were assigned beginning with Figure 1. A starting peak is chosen arbitrarily from this spectrum. For example, the peak located at (4.720 ppm, 4.035 ppm) was selected. This gives the locations of the H_3' and H_4' respectively (refer to Figure 2) of one backbone sugar ring. The H_1' is determined by finding the peak on Figure 3, which corresponds to the H_3'. For the above example, the H_1' is located at 5.525 ppm. Finally, the H_2' and H_5' are identified using Figure 4. Vertical lines are drawn at the H_1' and H_3' locations. Next, connectivities between peaks are found. This occurs when two peaks, one on each vertical line, can be connected by a horizontal line. Connectivities between four to six peaks should be found for each backbone ring. In the example, the two H_2' peaks are located at 1.72 ppm and the two H_5' peaks are at 2.18 ppm. Here, the H_2' peaks are located outside of the range for the H_5' peaks and are, therefore, easily assigned. However, in this region, many of the peaks will overlap, resulting in ambiguous assignments.

TABLE 1: Chemical Shift Ranges for Important Protons

Proton	Range	Molecule
H_1	5.5 - 6.1	(backbone)

DISCUSSION

Figure 5 shows the one-dimensional spectrum of the unmodified and the modified oligonucleotides. The upper and lower curves represent the unmodified and modified oligonucleotides respectively. In the upper curve, the three small peaks (labelled 'A') correspond to the thymine methyls on the single stranded oligonucleotide. The two larger peaks (labelled 'B) correspond to the thymine methyls on the duplex. The thymines in the duplexed oligonucleotide are held in rigid conformation. In this conformation, the outer thymines would be chemically equivalent and produce only one peak in the spectrum. In the case of the free, or single stranded oligonucleotide, the thymines can adopt other conformations, resulting in nonequivalence of the outer thymines. This produces one peak for each of the thymines in the spectrum. These characteristics allow the identification of the peaks as belonging to either the duplexed or single stranded oligonucleotide.

In the lower curve of Figure 5, the three peaks labeled as 'A' result from the free, or single strand, oligonucleotide and the two peaks label 'B' to the modified duplex. The ratio of A to B increases when comparing the modified to the unmodified spectrum. Since the size of the peaks is directly related to amount of the species present, one can conclude that the amount of free oligonucleotide increases as well. This implies that the duplex is breaking apart signifying that it is less stable than the native duplex.

Scheme 1 outlines the destabilization process. If the 5-nitroindole assumes the position of adenine, the highlighted hydrogen comes in close proximity to the nitrogen on the thymine. Since the hydrogen carries a partial positive charge and nitrogen carries a full positive charge, they repel each other, causing the 5-nitroindole to pull away from this position allowing for hydrogen bonding with the two oxygens. The movement from the natural position causes a bulge in the oligonucleotide, forcing it to break apart. Therefore, the modified base is more structurally unstable than the native structure. Further studies will investigate the stability of the structure when the 5-nitroindole is paired with the other natural bases in the complimentary strand.

The ability of acridinium ester to generate light has made this compound important for use as a label in immunoassays because of the high sensitivity possible with chemiluminescence detection. This study examined the effects of buffer concentration, pH, and complexing agents on the chemiluminescence of 9-phenyl acridinium ester. Concentrations of 0.200 M to 0.025 M potassium phosphate buffer at pH 6.0 to 8.0 were examined as well as similar concentrations of Tris buffer at pH 7.0 and 8.0. In general, an increase in light production was noted as buffer concentration was decreased. Using *gamma*-cyclodextrin as an additive was found to enhance chemiluminescence at pH 2.5 but *beta*-cyclodextrin had no appreciable effect.

INTRODUCTION

Chemiluminescence can be defined as the production of light resulting from a chemical reaction [1]. The study of this is important because detection of chemiluminescence is very sensitive and has a low background signal. Phenyl acridinium ester (see figure 2) was studied in this experiment for three main reasons: it is water soluble, it has a relatively high luminescent yield (approximately 0.1), and it can be conjugated to other molecules (i.e. proteins) to be used as a probe or label for immunoassays using high performance liquid chromatography. The variables studied were the effects of pH, concentration and type of buffer, and additives to the solvent. Especially, the rate of decay of luminescence versus time of the ester in solution was examined. This is a concern when doing an HPLC immunoassay. If there is a decay on the yield of luminescence of the ester, one could not accurately quantify the amount of molecule labeled with the ester without taking into account the decay. That is, one's signal would decrease with time even though the same amount of label were present.

EXPERIMENTAL

Luminometer measurements

All luminescence measurements were made using an Optocomp luminometer form MGM Instruments (Hamden, CT). Sample measurements were accomplished by the addition of two reagent solutions (75 µL each) to a test tube containing 150 µL of an acridinium ester solution. The reaction was initiated by addition of a hydrogen peroxide solution (in 0.1 N HNO_3 for stability) followed by addition of NaOH solution. The acridinium ester solutions typically contained 3×10^{-11} M phenyl acridinium ester in a pH 2.5 0.1 M phosphate buffer before dilution. Twenty-five µL of this solution was transferred into a 100 mL flask and diluted to volume with the desired solvent or buffer. The solvent or buffer was either Phosphate buffer or Tris buffer at different pHs and molarities or was water adjusted with strong acid or base to pH. Timing was initiated at the dilution time.

Reagents

9-phenyl acridinium ester (i.e. 9-phenoxy-10-methyl acridinium fluorosulfonate) was synthesized from acridine-9-carbonyl chloride as described in the literature [2]. Triton X-100 and *gamma*-cyclodextrin were from Sigma Chemicals (St. Louis, MO). Tris (Base) was from Schwarz/Mann (Orangeburg, NY).

RESULTS

Definitions: When "baseline values" or "baselines" is mentioned, this is the average of the readings taken after there was no more significant change in luminescence or the readings taken after one and a half hours in solvent. Peak values are first response readings from the luminometer. Typically, the first response was the largest one. When an unbuffered solution of a specific pH was called for, nanopure water was brought to pH with HCl or NaOH.

Additives

Because the effect of Triton X-100 on luminescence had been studied before [3], this study concentrated on comparison of Triton X-100 with unbuffered solutions and with *gamma*-cyclodextrin. The Triton did increase the total luminescence but seemed to have little or no effect on the decay of luminescence. Because the initial luminescence was relatively high compared to unbuffered solutions, but the baseline value was not as dramatically different, the decay of this curve (taken as the natural log of the curve) was faster than first order. The natural logarithm of the response versus time plot still had a very noticeable curve.

In the cyclodextrin studies, there was a linear increase of luminescence versus concentration from 0.01 to 0.1 M. Also, when in cyclodextrin and phosphate buffer (PB), there was no decay of response like with Triton X-100.

Buffers

The decay seen in response of luminometer readings versus time was not unique to one type of buffer. Both phosphate buffer and Tris (base) buffer showed a decay at different pHs with Triton X-100. Concentrations of buffer in specific pHs were studied. Results show the following general trends:

Peak Comparisons	
pH	Observation
6 (PB)	chemiluminescence decreased with decreasing buffer concentration
7 (PB)	no appreciable effect
8 (PB)	chemiluminescence increased with decreasing buffer concentration
8 (Tris)	chemiluminescence decreased with decreasing buffer concentration
Baseline comparisons	
pH	Observation
2.5 (PB)	no significant change
6 (PB)	no significant change
7 (PB)	small increase in luminescence with decreasing buffer concentration
8 (PB)	chemiluminescence increased with decreasing buffer concentration

Figure 1: general trends of luminescence with regard to pH

pH effects

Peak values and baseline values were studied. For the peak value studies, in general, unbuffered solutions demonstrated a slight rise in luminescence until pH 8. After pH 9, there was a sharp drop of luminescence. Buffered solutions showed a decline in luminescence with increase in pH from pH 6 to 11, with a leveling off from pH 10 to 11 (see figure 3). Baseline studies an increase in luminescence from pH 6 to 8 in unbuffered solutions with triton. In unbuffered solutions without triton, There was a general drop in luminescence from pH 6 to 9 and a sharp drop at pH 10. Buffered solutions once again showed a decline in luminescence with increasing pH. The decline is sharp from pH 6 to 8 and then bottoms out from pH 8 to 10 (see figure 4).

CONCLUSIONS

Additive effects

The addition of Triton X-100 and *gamma*-cyclodextrin could be enhancing the luminescence of the acridinium ester by the orientation of the ester in the micelles. Also, the hydrophobic environment provided by these micelles could be increasing the reactivity of the ester. Ion pairing increases significantly in micelles. This could explain the sharp decays in luminescence with triton.

Buffer effects

The buffers in neutral to high pHs could be forming an ion-pair with the ester. This would inhibit the luminescence by the formation of a less luminescent species. The production of light depends on reaction of the peroxide ion with the carbonyl (see figure 2). Any other ions which could pair there would block the peroxide ion from reacting, and hence block light production.

BEST COPY AVAILABLE

pH effects

At very high pHs (10, 11), the phosphate buffer seems to somewhat protect the acridinium ester from attack by the hydroxide ion and formation of the pseudo-base and increasing the likelihood of the dark reaction. However, at lower pHs, no significant decay is seen unless there is a buffer present. This could be the ions in the buffer solutions attacking the micelles and preventing them from helping the luminescence.

Future studies will include a larger range of pHs. Also, the effects of borate buffer and ionic additives will be investigated. At present, kinetics studies of the binding of *gamma*-cyclodextrin to the acridinium ester are underway.

It is desirable to develop a method of analyzing surfactant concentration and surface tension lowering effect without time consuming procedures or extensive preparation. Past research has shown that information can be obtained about the surface tension of a liquid by measuring the physical properties of a repeating drop formed by the flow of liquid out of the end of a capillary. This method has been suggested as a means to detect and characterize surfactants. A Dynamic Surface Tension Detector (DSTD) has been developed which is based upon measuring the pressure between the air-liquid interface of the expanding drop. This pressure-based data provides dynamic surface tension, surface adhesion, surfactant loading and viscosity data for each drop of solution. Common surfactants such as sodium dodecyl sulfate were used to characterize the detector and then industrial and biological surfactants examined and compared. Results will be presented which demonstrate the great potential the DSTD shows coupled with flow injection analysis and liquid chromatography.

INTRODUCTION

Surfactants are comprised of both polar and nonpolar functional groups. They preferentially migrate to surface interfaces to minimize unfavorable interactions with the bulk solvent. At the surface surfactant molecules disrupt the strong interactions of the solvent and lower the surface tension of the solution. Surfactants are widely used commercially as flow improvers, wetting and leveling agents, and emulsifiers.

Traditional methods of measuring surface tension such as contact angle, drop weight, and Wilhelmy plate are used under static conditions.[1] Other systems rely on secondary analyte features for detection, such as fluorescence and mass spectrophotometry, or rely on extensive sample preparation.[2] The Dynamic Surface Tension Detector can be used in real time analysis, both in industrial processes and in conjunction with flow injection analysis and liquid chromatography.

Previous research has demonstrated that surfactants can be detected by examining the drop detachment rate of drops falling from a capillary tip.[3] A previous version of the dynamic surface tension detector used a laser trigger to measure drop detachment rates.[4,5] This idea has been modified and a method of detection which offers multidimensional and kinetic data has been developed. Rather than measuring the drop detachment rate with a laser trigger, the pressure differential across the drop is measured during the entire drop cycle (drop formation, growth, and detachment). This detector yields the drop detachment information, as well as information about the formation of the drop and the kinetics of surfactant migration.

THEORY

An aqueous sample flows through a length of capillary tubing and a succession of drops are formed at the end of a capillary tip. A pressure sensor connected to the specially

The condition for drop detachment occurs when the force of gravity on the drop becomes stronger than the force of the liquid clasping on the tip. This condition is given by:

$$2\pi R'\gamma = \rho V G \qquad (1)$$

where R' is the effective radius where the liquid clasps the tip, γ is the surface tension of the solution, ρ is the density of the solution, V is the volume of the drop, and G is the gravitational force constant. All of these variables can be considered constant within a given drop except the volume of the drop (V). The density of the solution can be considered essentially that of the solvent because of the low concentrations of surfactant which produce large surface tension lowering effects. The solution is pumped at a constant flow rate, so that volume equals volumetric flow rate times time, and the surface tension is proportional to the time of detachment.

The surface tension induced pressure difference is related for a drop of radius r to the surface tension γ by the following equation:

$$P_{ST} = 2\gamma / r \qquad (2)$$

The pressure difference due to viscosity η is expressed by the Poiseuille equation:

$$P_V = 8\eta L F / (R^4 \pi) \qquad (3)$$

where η is liquid viscosity, L is the capillary length, F is the volumetric flow rate, and R is the inside radius of the capillary tip.

The signal is composed of P_{ST} and P_V and is therefore the sum of the previous two equations. The contributions of surface tension, viscosity, and adhesion of the solution to the surface of the capillary tip must be understood in order for the detector's performance to be optimized. The pressure difference due to viscosity does not vary with time or drop growth, but the pressure due to surface tension does vary with time because the drop radius r changes with time. An adhesion effect causes the force of the liquid clasping to the tip to be stronger and results in the drop clinging to the tip longer and therefore producing a longer drop detachment time (eq. 1).

EXPERIMENTAL:

The experimental apparatus is shown in Figure 1. Water was delivered with a syringe pump (Isco µLC-500, Lincoln, NE) to an injection valve (Rheodyne 7125, Cotati, CA) fitted with a fixed volume injection loop of 200 µL. The pressure sensor connected to the capillary tip is shown in Figure 2. The pressure sensor contains a thin metal membrane which is compressed and extended by less than 5 micrometers and is sensitive to pressure changes as little as 10^{-4} PSI. Detection limits vary by surfactant, but detection limits in the low parts per million have been achieved.

The pressure readings are recorded in arbitrary units which can be converted into PSI by calibration with a volt-meter. The data is collected on computer with a Keithley-Metrabyte data acquisition board. The collection rate for this work ranged from 60 to 300 points per second. The data collection rate does not appear to be a limiting factor in data precision. The signal to noise ratio is approximately three to one or better.

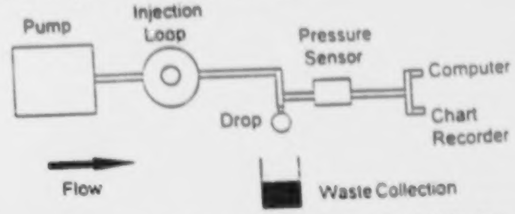

Figure 1. Instrument design. For the data presented in Figures 3-5, the flow rate was 85 µL/min, the solvent was water, and the sample volume injected was 200 µL with a capillary tube volume of 300 µL to achieve the desired diffusion. Samples are introduced to the fixed volume injection loop and injected into the flow, passing through a length of capillary tubing and forming a repeating drop at the capillary tip.

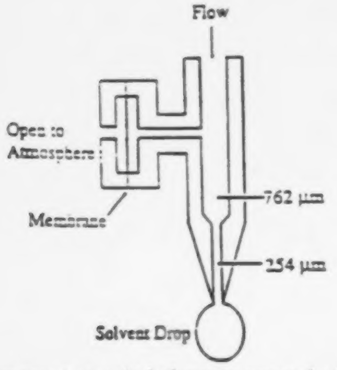

Figure 2. A pressure sensor records the pressure across the drop and passes the signal to both a chart recorder and a computer via a data acquisition board. The tip is specially machined to avoid back-pressure and a side-arm in the stainless steel tip allows the membrane in the pressure sensor to register the pressure across the air-liquid interface of the drop.

RESULTS AND DISCUSSION

The pressure signal relates directly to the stage of drop formation, as described below and illustrated in Figure 3. The signal is at its minimum when one drop detaches from the capillary tip and the next drop begins forming. At first there is liquid only inside the capillary tip. Since there is a constant flow from the pump, the liquid is pushed to the outside of the tip where it first appears as a slight bulge. During this time the pressure signal rises steadily. The pressure maximum occurs approximately when the liquid "pops" into a hemisphere. The hemisphere becomes a sphere almost immediately and as the sphere grows in size the pressure signal decreases until the drop reaches its maximum size and detaches from the capillary tip. Drop detachment occurs when the volume is large enough that the force of gravity overcomes the force of attachment to the tip as shown in equation 1. This is the pressure minimum which is the end of one drop cycle and the beginning of another. The drop is not actually perfectly spherical but because of the excess free energy at the surface it approximates a sphere very closely.

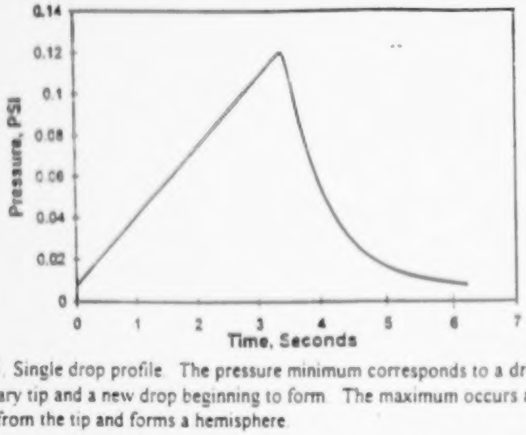

Figure 3. Single drop profile. The pressure minimum corresponds to a drop detaching from the capillary tip and a new drop beginning to form. The maximum occurs as the liquid emerges from the tip and forms a hemisphere.

In order to develop a means to compare data using the detector, the maximum and minimum pressure signal and the time from minimum to minimum for consecutive drops from the capillary tip were examined. At the pressure minimum, one drop detaches and the next begins to form; from one minimum to the next is the time of a drop. From the pressure minimum to the maximum is the total pressure. The presence of a surfactant causes both the total pressure and time to change. As predicted by equation 2, when the surface tension is lowered, the pressure due to surface tension is also lowered. At the pressure maximum the

BEST COPY AVAILABLE

radius of the drop is always the same, so the pressure signal and surface tension of the solution should directly relate. According to equation 1, surface tension at the instant of drop detachment is proportional to volume, provided the other factors remain constant. Since the flow rate remains constant, the smaller volume resulting from a lower surface tension is recorded as a shorter drop time.

Changes in surface tension relative to some baseline surface tension of a flowing solvent can be determined by calculating the change in time or change in pressure. The change in pressure (ΔP) and change in time (Δt) are found by subtracting the pressure signal or time of a drop containing surfactant from the pressure signal or time of a drop containing only solvent. The solvent used is water which makes the baseline surface tension 72 dynes per centimeter. The greater the concentration of surfactant, until it forms a monolayer or reaches the critical micelle concentration, the greater the change in surface tension and therefore in pressure signal or drop time. A drop profile is the plot of pressure signal versus time for a single drop. Figure 4 shows the drop profiles for five concentrations of SDS (sodium dodecyl sulfate) in 500 ppm TBA (tetrabutyl ammonium) compared to a drop profile for pure water. The 10 ppm SDS drop pressure is slightly lower than pure water and its time is slightly shorter than pure water. The 60 ppm SDS drop pressure is much lower than that of water and the drop time is significantly shorter than water. These differences confirm that the DSTD detects the lowering of the surface tension of water by SDS/TBA.

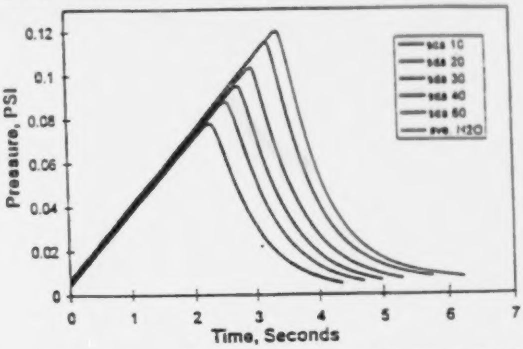

Figure 4. Overlay plot of drop profiles for water and five concentrations of SDS in 500 ppm TBA. SDS concentrations are in ppm.

Although the drop profiles in Figure 4 have different sizes, all the SDS drop profiles have the same general shape. Different surfactants can be characterized and kinetic data can be interpreted from the shape of the drop profiles. At the very least, the multidimensional data can be used to distinguish surface tension lowering effects from other phenomena such as adsorption.

Shown in Figure 5 are several drop profiles of FC-171, an industrial surfactant manufactured by 3M, overlaid on the drop profiles of SDS and water. Previous detectors relying on drop detachment rate alone would not see that FC-171 lowers the surface tension because the drop time remains the same for increasing concentrations. At the pressure maximum, however, the surface tension lowering effect is clearly manifest. The hydrophobic FC-171 adsorbs or adheres slightly to the stainless steel tip.

When a smaller sample of a higher concentration is injected and greater diffusion is allowed by increasing the length of the capillary tubing leading to the capillary tip, a gaussian signal peak is obtained. The concentration of each drop increases slightly to a maximum and then decreases until the drops consist only of water. Each drop is examined and its ΔP and Δt are found and divided by a baseline P and t. For the time t, the time of a water drop is the baseline t. For the pressure P, the total pressure of a water drop is a baseline P. $\Delta P/P$ and $\Delta t/t$ can be plotted either against one another or against the drop number. In Figure 6 as the surfactant concentration increases to a maximum, $\Delta P/P$ and $\Delta t/t$ increase. As the surfactant concentration decreases, $\Delta P/P$ and $\Delta t/t$ decrease as well. As expected from equations 1 and 2, $\Delta P/P$ and $\Delta t/t$ are at their maximum when the concentration of surfactant is at its greatest and therefore the surface tension lowering effect is greatest.

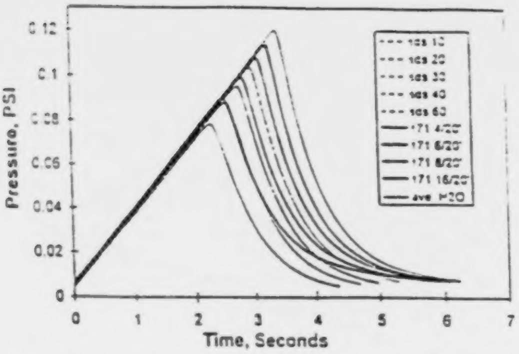

Figure 5 Overlay plot of drop profiles for water, SDS in TBA, and FC-171 SDS concentrations are in ppm and FC-171 concentrations are in µL surfactant per mL water.

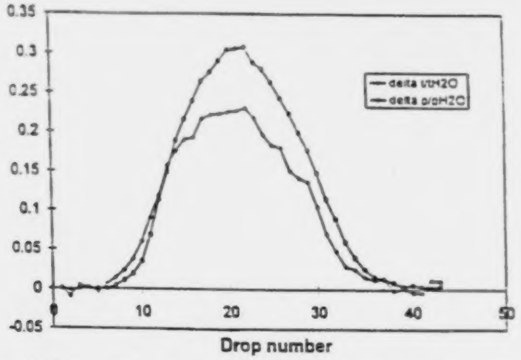

Figure 6 Plot of $\Delta P/P_{H2O}$ and $\Delta t/t_{H2O}$ versus drop number for injection of 250 ppm SDS in 500 ppm TBA. Initial and final drops shown consist of only water As varying concentrations of surfactant go through the detector $\Delta P/P_{H2O}$ and $\Delta t/t_{H2O}$ increase as a result of the lowering of the surface tension of the solution

CONCLUSIONS

The pressure-differential based dynamic surface tension detector shows great promise for surfactant detection and characterization Through the manipulation of time and pressure data, information about surface tension can be acquired Further studies will focus on applications of the detector to liquid chromatography and further test the capabilities of the detector

The focus of the research is to determine how the regulatory light chains (LC20) of smooth muscle myosin (SMM) interact with the myosin heavy chains (HC) Regulatory light chains containing a 6xHistag marker for purification purposes were expressed from *Escherichia coli* and separated by affinity chromatography The purified LC20s were labeled at the single cysteine residue with benzophenone-4-iodoacetamide (BPIA), a photoreactive cross-linker, and the labeled LC20s were exchanged onto native SMM Investigations using SMM 10S folded form, filamentous form, and 6S monomer form provided evidence that for non-phosphorylated myosin, the 6xHistag does not affect HC-LC photocross-linking ability Analysis showed that HC-LC cross-linking ability of the BPIA attached to the C-terminal domain of the native LC20 differs from cross-linking ability of the probe when located in the N-terminal of double mutant A23C/C108A LC20 Conformation-dependent interactions of the myosin HC with the N-terminal of LC20 differ from those interactions with the C-terminal of LC20 Future studies will use phosphorylated double mutant LC20 exchanged myosin to compare the effects of phosphorylation on cross-linking ability These studies will aid in the determination of the location of HC-LC cross-link formation and give information about conformation changes that occur in myosin during contraction and regulation These studies should lead to a greater understanding of regulation in SMM

BACKGROUND

Smooth muscle lines the organs of the gastrointestinal tract and the walls of blood vessels Smooth muscle myosin (SMM) is the molecule that regulates contraction of smooth muscle SMM consists of a globular head region, a neck region, and a long coiled-coil tail SMM molecules are hexamers composed of two heavy chains and two pairs of light chains (essential and regulatory light chains) attached to the heads of the heavy chains

Regulation in SMM is phosphorylation-dependent A Ca^{2+}-calmodulin/myosin light-chain kinase complex phosphorylates SMM Upon hydrolysis of MgATP into the products ADP and P_i, the head shifts to a high-energy configuration which binds to actin filaments Catalyzed by myosin light-chain phosphatase, the release of P_i from SMM causes the head to reconfigure into a low-energy binding state This change in conformation causes tension and initiation of the power stroke, which results in the movement of actin filaments It is this "sliding" of actin and myosin filaments which causes muscle contractions The cycle is completed when ADP is released from myosin, leading to muscle relaxation[1]

In vitro, purified SMM exists in three forms In the presence of ATP, SMM exists in a soluble 10S monomer form, in which the tail forms a cross-link with its own head The 10S form has low ATPase activity In high ionic strengths, the 10S form is destabilized and exists as a soluble 6S monomer in which the tail is straightened The 6S monomer has intermediate ATPase activity and exists in equilibrium with the inhibited filament form The filaments become active (display high ATPase activity) upon phosphorylation of the regulatory light chains See Figure 1A, 1B, and 1C for SMM configurations

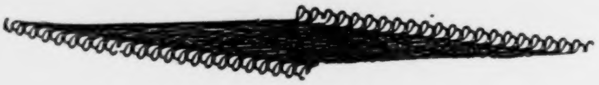

Figure 1A Filamentous SMM

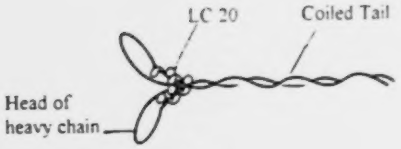

Figure 1B 6S SMM

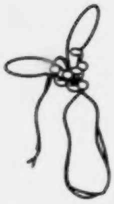

Figure 1C 10S SMM

The structure of the 20kDa regulatory light chain (LC20) is of interest because phosphorylation of the LC20 regulates myosin activity Upon phosphorylation, the LC20 and the myosin head change conformation, resulting in muscle contraction A photoreactive cross-linking probe, benzophenone-4-iodoacetamide (BPIA) Figure 2, was placed onto the single cysteine of purified unphosphorylated LC20 The labeled LC20 was exchanged for the native LC20 on purified chicken gizzard SMM The probe was irradiated, and gel analysis of the cross-links was used to discover the structural relationships involved in unphosphorylated LC20s

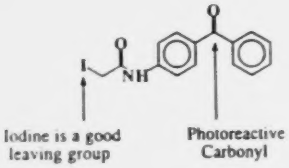

Figure 2 Structure of BPIA

An important question to be answered before continuation of the experiments was does the 6xHistag marker affect photoaffinity cross-linking ability of the labeled LC20s to the heavy chain (HC)? If so, then the 6xHistag must be cleaved before irradiation of the samples The 6xHistag to the LC20 was utilized in affinity chromatography and allowed for purification of the LC20 from *E. coli* If the Histag did not affect cross-linking ability, the Histag would be left on during irradiation, so that affinity chromatography could also be used to purify the HC-LC cross-links after irradiation of the labeled myosin

A future goal of the research is to repeat the cross-linking experiment using phosphorylated LC20 to compare the structural differences between unphosphorylated and phosphorylated LC20 in order to determine the conformational changes that occur during SMM regulation

MATERIALS AND METHODS

6xHistag LC20s were cloned and expressed from *E. coli* The cells were homogenized and the LC20s containing a 6xHistag marker were purified by affinity chromatography The 6xHistags of the LC20s chelated with the resin used for chromatography, while the remaining homogenate material was in the supernatant The LC20s were then eluted from the resin using an imidazole-based buffer solution

Two different constructs of the LC20 sequence were used a wild type (WT) construct with the native light chain sequence and a construct with a double mutant sequence (A23C, C108A) The LC20s were then labeled at the single cysteine (C108 for WT, A23C for double mutant) with BPIA, following the procedure described by Olney, et al[3]

The labeled LC20s were then exchanged onto purified chicken gizzard SMM using a 20-fold excess of labeled LC20s The SMM and labeled LC20s were placed in ATP, dithiothreitol (DTT), and EDTA at 42° C for 30 minutes to promote the exchange of native LC20s with the labeled LC20s The LC20 exchange reaction conditions and procedures were performed as described by Facemyer and Cremo[2] and Olney, et al[1]

The solution containing the labeled SMM and free LC20s was placed into a Mg^{2+} buffer to promote the formation of SMM filaments The labeled SMM were separated from the free LC20s by centrifugation The SMM were dialyzed with different buffers to promote formation of 6S, 10S, and filament conformations [6S buffer conditions 0 5 M NaCl, 15 mM imidazole pH 6 6, 1 mM EGTA, 10 mM $MgCl_2$ 10S buffer conditions 10 mM NaP, pH 7 5, 1 mM $MgCl_2$, 0 1 mM EGTA, 125 mM NaCl, 0 5 mM ATP Filament buffer conditions 15 mM imidazole pH 6 6, 10 mM $MgCl_2$, 125 mM NaCl, 1 mM EGTA] The 6S, 10S, and filament samples were then irradiated to activate the BPIA probe and initiate cross-linking 4-20% Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and 8M urea gel electrophoresis were used to analyze the cross-link formations that resulted The 6xHistag was cleaved from some of the LC20s using a thrombin buffer 15mM Tris-Cl pH 7 5, 2 5 mM $CaCl_2$, 10 mM $MgCl_2$, 150 mM KCl, 2 mM DTT, and N_3

RESULTS

The Effect of the 6xHistag During Irradiation

To test whether the Histag affected cross-linking ability of labeled myosin, 4-20% SDS-PAGE analysis was performed on the samples in Figure 3 The samples analyzed by SDS-PAGE were unlabeled myosin control (lane 1), native LC20 C108 BPIA labeled myosin (lane 2), irradiated native LC20 C108 BPIA myosin (lane 3), myosin irradiated in a 10-fold excess of C108 BPIA free LC20 (lane 4), WT 6xHistag LC20 C108 labeled myosin (lane 5), and irradiated 6xHistag LC20 C108 labeled myosin (lane 6)

Myosin irradiated in the presence of free labeled LC20 (lane 4) did not form HC-LC cross-links, as indicated by the absence of the HC-LC cross-link band, therefore, the LC20s do not exchange during irradiation This meant that the labeled LC20s exchanged onto the native SMM during the exchange reaction would not come off during irradiation Levels of HC-LC cross-linking were similar in myosin filaments containing native labeled LC20 (lane 3) and WT Histag LC20 (lane 6) It was concluded that the Histag did not affect the cross-linking ability of the sample

A similar experiment was performed with 6xHistag LC20 A23C/C108A BPIA labeled myosin versus thrombin-cleaved LC20 A23C/C108A labeled myosin to determine whether the Histag affected photoaffinity cross-linking ability of SMM Figure 4 shows the 4-20% SDS-PAGE analysis of the experiment with the double mutant LC20 unlabeled myosin control (lane 1), 6xHistag double mutant BPIA labeled LC20 (lane 2), irradiated 6xHistag LC20 A23C/C108A BPIA labeled 10S myosin (lane 3), irradiated 6xHistag LC20 A23C/C108A BPIA labeled filamentous myosin (lane 4), irradiated 6xHistag LC20 A23C/C108A BPIA labeled 6S myosin (lane 5), LC20 double mutant labeled myosin (lane 6), irradiated LC20 double mutant labeled 10S myosin (lane 7), irradiated LC20 double mutant labeled filamentous myosin (lane 8), irradiated LC20 double mutant labeled 6S myosin (lane 9), unlabeled myosin control (lane 10)

In double mutant LC20, the levels of cross-linking formation differed with conformation The most cross-linking occurred in filamentous form (lanes 4 and 8), the least cross-linking occurred in 6S form (lanes 5 and 7) Levels of conformation-dependent cross-linking in irradiated samples were the same in myosin which contained the 6xHistag (lanes 3-5) and in myosin in which the 6xHistag was cleaved with thrombin (lanes 7-9) The 6xHistag marker did not affect the cross-linking ability of the sample

The Effect of BPIA Location on HC-LC Cross-link Formation

The dependence of probe location on the formation of cross-links was examined by comparison of the conformation-dependent levels of cross-linking that occurred in native LC20 C108 labeled myosin versus 6xHistag LC20 double mutant labeled myosin Figure 5 shows the 4-20% SDS-PAGE analysis of the constructs unlabeled myosin control (lane 1), native LC20 BPIA myosin (lane 2), irradiated native LC20 BPIA 10S myosin (lane 3), irradiated native LC20 BPIA filamentous myosin (lane 4), irradiated native LC20 BPIA 6S myosin (lane 5), 6xHistag LC20 double mutant myosin (lane 6), irradiated 6xHistag LC20 double mutant 10S myosin (lane 7), irradiated 6xHistag LC20 double mutant filamentous myosin (lane 8), irradiated 6xHistag LC20 double mutant 6S myosin (lane 9), unlabeled myosin control (lane 10)

With placement of the probe on C108 of the native light chain in the C-terminal domain (lanes 2-5), cross-linking was very efficient in 10S myosin (lane 3), less efficient in filaments (lane 4), and did not occur in the 6S monomer (lane 5) In contrast, placement of the probe on A23C in the N-terminal domain of the LC20 (lanes 6-9) resulted in HC-LC cross-linking primarily in filaments (lane 8), less so in 6S myosin (lane 9), and in very low levels in the 10S conformation (lane 7)

The ability of BPIA to form HC-LC cross-links is dependent upon the site-specific placement of the probe on the LC20 Cross-link formation was conformation-dependent in both native and double mutant LC20 constructs, however levels of conformation-dependent cross-linking differed in the two

CONCLUSION

Evidence from the photoaffinity cross-linking experiments with non-phosphorylated WT 6xHistag LC20 C108 BPIA labeled myosin and with non-phosphorylated 6xHistag

LC20 A23C/C108A BPIA labeled myosin shows that the Histag does not affect cross-linking ability These experiments demonstrated that the Histag would not need to be removed before irradiation of the samples, and that thus, the Histag could be used in purification of the HC-LC cross-links However, further research (not shown here) has revealed that the Histag affinity chromatography technique cannot be used to purify the HC-LC cross-links because the HC interferes with Histag binding to the chelating resin While the Histag does not alter cross-linking ability, another method (other than using the Histag with affinity chromatography) must be found to purify the HC-LC cross-links

Cross-linking is conformation-dependent Heavy chain-light chain cross-link formation differs in myosin with native LC20 labeled at C108 from myosin with LC20 labeled at A23C Cysteine 108 is located at the C-terminal domain of the LC20, while A23C is located in the N-terminal domain Based on the data presented, HC-LC interactions change with conformation and with respect to the location of the probe on the two domains of the LC20

Investigations to study the effect of phosphorylation on cross-linking ability of A23C/C108 LC20 are in progress Goals of future studies are to determine the precise location of the HC-LC cross-linking in specific conformation, to discover why HC-LC interactions differ with conformation, and to increase overall understanding of how phosphorylation of LC20 regulates smooth muscle contraction

5-Nitroindole is considered a good universal base for hybridizing with other base pairs in oligodeoxynucleotides. This is due to its duplex stability and affinity for all nucleotides. To show this we determined the melting point by heating the modified oligonucleotides until they became destabilized. Then we compared this data to the original melting points of unmodified oligonucleotides. The results of this study show that the oligonucleotides containing the modified base were more stable than the the unmodified duplexes.

INTRODUCTION

The object of these experiments was to determine the feasibility of using 5-nitroindole as a universal base. We studied the stability of a series of oligonucleotides with and without incorporation of 5-nitroindole. This was done by comparing the melting temperatures of the native and modified oligonucleotides. Analysis of the resulting data was then used to show how the 5-nitroindole effects the stability of the duplex when incorporated, and more specifically how the 5-nitroindole pairs with each of the four naturally occurring bases.

A universal base is a base that pairs indiscriminately with all dNTPs (deoxyribonucleic triphosphates) with no substantial decrease in stability from that of the natural pairing partner. The stability of the oligonucleotide is dependent upon intermolecular interactions between the base pairs. One of the most important interactions stabilizing the double stranded structure of the oligonucleotide is hydrogen bonding between the base pairs in the two strands (see figure 1). Many bases have been tried as a universal base, but were not successful because of their inability to hydrogen bond with all possible 'complementary' bases. An example is hypoxanthine. It does form hydrogen bonds with all dNTPs to varying degrees. However in laboratory experiments with PCR, where it is used in the primer, it exclusively duplexes with cytosine.

5-Nitroindole is a base that is currently being looked at in this study as a universal base. It is considered a good universal base because it does duplex with all dNTPs, showing increased stability at low salt concentrations. This shows that 5-nitroindole is a good universal base because it meets both of the necessary requirements.

To accomplish the task of evaluating 5-nitroindole is as a universal base it was heated gradually until it reached its melting point. This was done by taking a UV spectrum of the solution periodically as it was being heated. The resulting data was then analyzed to determine the stability of the modified duplex relative to the oligonucleotides containing the naturally occurring base pairs.

The melting point (T_m) of the oligonucleotide is an indication of the relative stability of the molecule. By comparing the T_m's for the native and modified oligonucleotide we can determine the stability of the modified oligonucleotide with respect to the native. This information can be used in conjunction with structural studies to learn how the chemical and physical differences between the universal and naturally occurring bases effect the structure of the modified oligonucleotide complex.

HYDROGEN BONDING BETWEEN A MODIFIED BASE AND NATIVE BASES

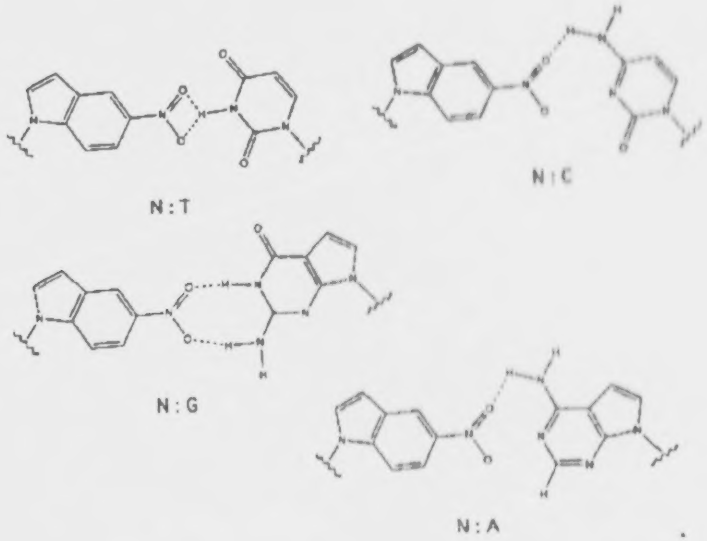

FIGURE 1

METHODS

The oligonucleotides were synthesized on an ABI DNA synthesizer using standard phosphoramidite chemistry and purified by HPLC (high performance liquid chromatography). Each DNA oligonucleotide was placed in a solution of 20mM citrate and 3mM NaCl. The solutions were then gradually heated, and changes in the structure were followed at 260nm by UV spectrometry (Gilford UV spectrometer) (See figure 2) From plots of the absorbency at 260nm vs. the temperature, the melting points of the oligonucleotides were obtained.

RESULTS AND CONCLUSIONS

The data collected from these experiments using low salt concentrations and

LOW SALT CITRATE BUFFER OLIGONUCLEOTIDE MELTING

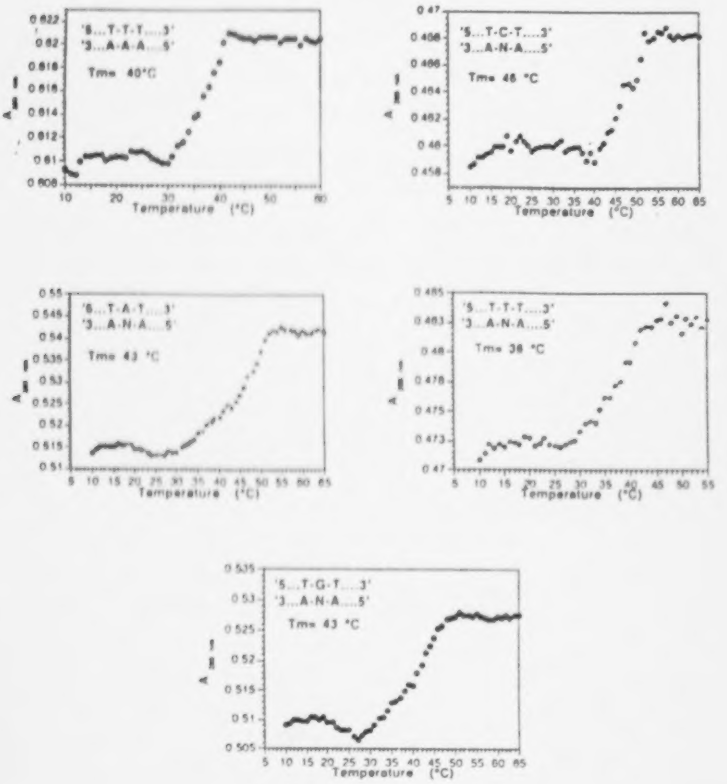

FIGURE 2

that taken from the Brown study using high salt concentrations are compared in table 1. Both studies used the normal T_m of natural oligonucleotides as 40 C. The table shows the difference between the normal and modified T_m s in degrees Celsius.

table 1 temperature differences between modified and native T_m oligonucleotide

	A	T	G	C
High conc.	-5	-7	-7	-4
Low conc.	+3	-4	+3	+6

These results show that the T_m of the 5-nitroindole actually increase the stability of the oligonucleotide at low salt concentrations especially in those oligonucleotide duplexes where the 5-nitroindole is paired to A,G or C. This can be seen by the increase in the melting temperatures of these duplexes. This indicates that 5-nitroindole acts as a good universal base. At higher salt concentrations though the 5-nitroindole was less stable than its natural counterparts. The different salt concentrations were used to show an emphasis on different contributions to the stability of the duplex. At high salt concentrations the structure of the modified DNA strand is reinforced by ionic interactions particularly in the phosphorous backbone of the DNA. At low salt concentrations the DNA strand is stabilized to a greater extent by the hydrogen bonding of the base pairs.

ACKNOWLEDGEMENTS

Thin, transparent chitosan films have been prepared from dilute acetic acid gels. Interest is focused on the incorporation of porphyrins to prepare films that have interesting optical properties. Studies to date have involved the derivatization of porphyrins for subsequent covalent bonding to the chitosan polymer, and the synthesis of other *meso*-tetraarylporphyrins for doping the films. No reactivity between chitosan's amino or hydroxy substituents and *meso*-tetrakis(4-carboxyphenyl)porphyrin, H_2TCPP, was observed in different solvents. Consequently, the more reactive acid chloride derivative, *meso*-tetrakis(4-chlorocarbonylphenyl)porphyrin, was prepared by refluxing H_2TCPP in thionyl chloride. *meso*-Tetraphenyl-porphyrin-doped chitosan gels produced pale blue transparent films. Fluoroporphyrins such as *meso*-tetrakispentafluorophenylporphyrin, H_2TF_5PP, and its Ni(II) derivative have also been synthesized to function as potential dopants.

INTRODUCTION

Due to their potential applications in optical communications, data storage, and electro-optical signal processing, molecules with nonlinear optical (NLO) properties under vigorous investigated.[1] Many polymeric materials with functional chromophores appear to show interesting electronic properties with good processibility.[2] Chitosan is the only known amino polysaccharide and, along with several of its derivatives, forms liquid crystals, thereby providing a route to functional high temperature polymers with noncentrosymmetric structures displaying NLO properties.[3] Chitosan is the deacylated derivative of chitin, which is one of the most abundant organic resources on earth.[4] It is composed predominantly of sigma bonds, which precludes oxidation or extensive chemical reactions. This makes chitosan ideal for the fabrication of air-stable and visibly transparent thin films. These properties are also precisely those required of protective overlayers for organic light emitting devices to mitigate the degradative effects of oxidation and chemical reactions.[5] An essential process in the operation of electroluminescent organic light emitting devices is the transport of electrons, which is responsible for light emission.[6] Since chitosan can be readily functionalized,[7,8,9] the attachment of appropriate side groups to the polymer backbone should lead to efficient carrier transport. Particularly promising candidates as electron transporting functional dyes are porphyrins.[10] Additionally, porphyrins absorb visible light strongly.[11] To this end, chitosan-porphyrin films appear to be promising as components in optical devices and NLO materials.

An especially fruitful strategy involves incorporation of the dyes of interest into the polymer matrix. Therefore, in the present study, preliminary results of the formation of porphyrin-doped chitosan films are presented. The porphyrins prepared were characterized spectroscopically. A second route to interesting materials entails the direct bonding of chromophores to the polymeric backbone. To carry out this function, a reactive dye such as the porphyrin bearing acid chloride groups, was synthesized. This porphyrin may be more reactive in the proposed derivatization of the chitosan polymer than the parent acid derivative.

EXPERIMENTAL

Materials

Pyrrole was purchased from Aldrich Chemical Company and distilled under reduced pressure before use. Thionyl chloride, $SOCl_2$, was purchased from Fisher Chemicals and was freshly distilled prior to use. Practical grade chitosan and deuterated solvents were purchased from Aldrich. Thin layer chromatography plates (silica gel) were purchased from Kodak. *meso*-Tetrakis(4-carboxyphenyl)porphyrin (H_2TCPP) was purchased from Mid-Century Chemicals. All other chemicals were used without further purification.

Methods

Proton nmr experiments were conducted on a Varian YH400 MHz spectrometer at 300K and data was manipulated using Varian software in a Solaris Sparc™ environment. Absorption data was collected on a Beckman DU 7500 Series spectrophotometer at room temperature. Infrared studies were performed on a Nicolet 560Magna FTIR instrument using nujol mulls. Porphyrin isolations were achieved on neutral alumina (Eastman) via column chromatograpy (12in x 1in). Product purity was determined by TLC.

Synthesis

meso-Tetraphenylporphyrin (H_2TPP) was prepared by the Adler-Longo method of refluxing benzaldehyde and pyrrole in propionic acid for 1h under ambient conditions.[12] The resulting black solution was cooled to room temperature then further cooled on an ice bath. The insoluble product was collected by suction filtration and washed with small aliquots of propionic acid followed by diethyl ether. The shiny purple crystals were air-dried (15-17% yield). UV-vis($CHCl_3$, λ_{max}nm) 419, 516, 551, 591, 649. ^1H nmr($CDCl_3$, ppm) 8.85(8H, s), 8.25(1H, m), 7.80(4H, m), -2.65(2H, s).

meso-Tetrakis(2,3,4,5,6-pentafluorophenyl)porphyrin (H_2TF_5PP) was prepared by the Lindsey "high dilution" method.[13] In a typical experiment, 0.15 mmole (1.852mL) pentafluoro-benzaldehyde and 0.15mmol pyrrole (1.04 mL) were condensed in 1L dichloromethane in the presence of 125μL boron trifluoride etherate, BF_3:$O(CH_3CH_2)_2$, as catalyst. The flask was shielded from light by wrapping with aluminum foil. After 1h stirring, 5mL methanol was added to quench the reaction. Then 2.5g (3 equivalents) 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) was added and the slurry was stirred for an additional 15 min. The black mixture was concentrated on rotovaporization to about 50mL. The product was transferred to a 100 mL round-bottom flask and evaporated to dryness. The solid was scraped into a 50 mL fritted funnel (medium) and washed with 10 mL aliquots of methanol until the filtrate was almost colorless. The resulting purple solid was recrystallized by evaporation of a 1:1:1 chloroform:methanol:heptane mixture to give shiny purple crystals (30-40% yield). UV-vis ($CHCl_3$, λ_{max}nm(log ϵ)) 415(5.78), 463(5.44), 508(4.50), 584(4.94), 636(4.11). ^1H nmr ($CDCl_3$, ppm) 8.91 (8H, β-H, s), -2.92 (2H, N-H, s).

The Ni(II) derivative, $NiTF_5PP$, was prepared by refluxing 0.0845g (1.03 mmole) nickel chloride hexahydrate and an equal moles of sodium acetate with 0.1g (0.103 mmole) of porphyrin in 100mL acetonitrile for 24 h. The brown suspension produced a red solution and the solvent was evaporated to dryness. The resulting solid was chromatographed once on neutral alumina using 3:1 hexanes:chloroform as eluent. The purity of the fractions was determined by TLC. All similar fractions were combined and the solution was concentrated to 6 mL on rotovaporization. Equal volumes of methanol and heptane were added and the porphyrin was recrystallized to yield tinsel purple crystals (93% by integration of ^1H nmr signals). UV-vis($CHCl_3$, λ_{max} nm) 409, 524, 560. ^1H nmr ($CDCl_3$, ppm) 8.80 (8H, β-H, s).

Synthesis of the acid chloride derivative of H_2TCPP was as follows. Thionyl chloride (3mL) and 0.1g (0.0126 mmole) porphyrin in a 10mL round-bottom flask was refluxed on a water bath at 70-75°C. The condenser was equipped with a home-made gas trap. The solution turned green on warming and was stirred for 1h. The green porphyrin product was recovered by removal of the excess $SOCl_2$ under reduced pressure followed by drying under low pressure. UV-vis(DMF, λ_{max} nm) 420, 514, 547, 589, 647. ^1H nmr (DMF-d_7, ppm) 8.81(8H, β-H, s), 8.89, 8.88 (8H, m-H, d), 8.76, 8.74 (8H, o-H, d).

In the preparation of chitosan thin films, 2g of chitosan was added to 100 mL of 0.2M acetic acid in a 400 mL beaker. The white flakes dissolved slowly (overnight) on stirring to produce a viscous solution. The container was covered to prevent evaporation of the solvent. The pale-yellow gel was pipetted and cast onto a petri dish and air-dried. The chitosan plate was placed directly into a solution of 1M NaOH for 30 min to neutralize the acid and to loosen the film. This was followed immediately by two washings in deionized water using the same procedure as performed with NaOH. Another glass dish was placed directly on top of the chitosan plate to stabilize the system overnight. The film was then air-dried (12h) and the product was carefully peeled off the surface. The preparation process required about 3 days.

The fabrication of porphyrin-doped chitosan films followed the procedure above except that 100 mg of the porphyrin in acetic acid was added to 50 mL of gel prior to casting. The mixture was stirred for an additional 15 min to ensure homogeneity before pipetting.

RESULTS AND DISCUSSION

The synthesis of tetraphenylporphyrin, H_2TPP (1), proceeded via the Adler-Longo methodof refluxing starting materials in organic acid to produce modest porphyrin yields. On the other hand, the presence of the larger ortho-fluorine substituents in the target pentafluorophenylporphyrin, H_2TF_5PP (2), required dilute non-polar solutions to optimize yields (40%, equation 1). In the Adler sequence, autooxidation of the porphyrinogen formed porphyrin while the latter route required added oxidant (DDQ).

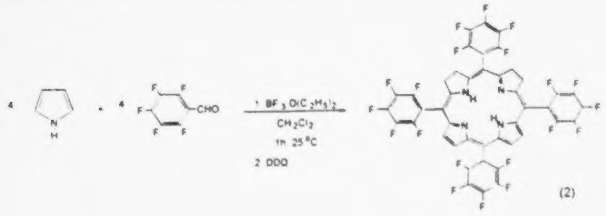

Figure 1. Synthesis of H_2TF_5PP

Insertion of nickel(II) into H_2TF_5PP required excess metal salt and added acetate as base to favor product formation (equation 2).[14] The original brown suspension produced a red solution in refluxing acetonitrile. The reaction was monitored by absorption spectroscopy and TLC. The porphyrins were all recrystallized to give shiny, purple crystals. Recrystallization of the solids from a 1:1:1 chloroform:methanol:heptane mixture was successful as a result of three factors: the differential vapor pressures of the solvents, the low solubility of porphyrin in methanol/heptane, and the high solubility of the polypyrrolic by-products in methanol.

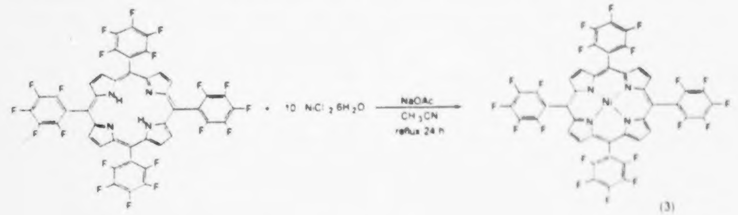

Figure 2. Preparation of $NiTF_5PP$

The free base porphyrins and $NiTF_5PP$ (3) were characterized by proton nmr and absorption spectroscopy and spectroscopic data was in agreement with published results.[15]

The initial route toward the bonding of porphyrin macrocycles to chitosan (5) used 4-carboxyphenylporphyrin, H_2TCPP (4) (equation 3). The porphyrin and chitosan was refluxed in several solvent systems such as acetone, aqueous acetone, DMF, 5wt% NaOH, and 10%

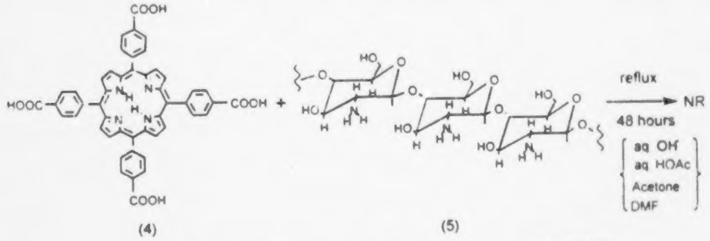

Figure 3. Attempted reactivity between Chitosan and H_2TCPP

aqueous acetic acid. The carboxyl substituent on the *meso*-phenyl rings was expected to undergo condensation with the chitosan substituents to form amide or ester linkages with the polymer. However, no reactivity occurred. Poor reactivity may have resulted from the lack of solubility of chitosan in all of the solvent systems or low reactivity of the porphyrin used. One approach to solving the solubility issue may lie in the preparation of soluble derivatives.

A better approach towards the derivatization of the chitosan backbone with H_2TCPP is proposed through reactivity with the acid chloride derivative of the porphyrin (6) (equation 4).

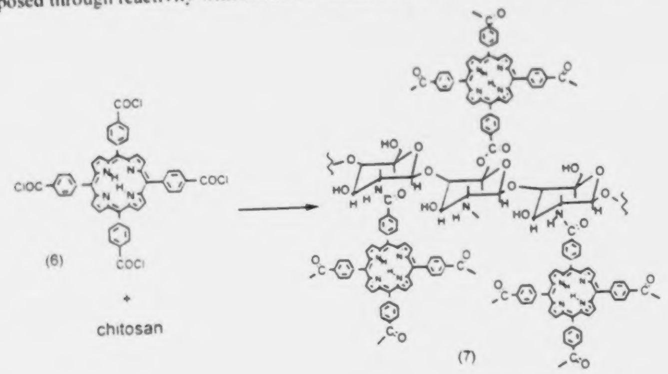

Figure 4. Proposed synthesis of porphyrin-chitosan polymer

Consequently, *meso*-tetrakis(4-chlorocarbonylphenyl)porphyrin, $H_2TClCPP$ (6) was synthesized.[16] The reaction was first conducted on microscale then the eaction was scaled up to 100 mg porphyrin. The solid was refluxed directly in excess thionyl chloride (equation 5). Initially, the porphyrin was insoluble in thionyl chloride. A green solution formed on warming, presumably due to the complexation of protons by the porphyrin pyrrolic nitrogens. Formation of the green porphyrin diacid[17] signaled that acid was liberated and indicated indirectly that the reaction was proceeding. The isolated solid was only moderate solubility in methanol. On the other hand, the starting material was highly soluble in methanol and showed slightly red-shifted Q-band absorbances relative to the product. Additionally, a downfield shift of β-pyrrole and phenyl ring protons of the product was observed, indicating a decrease in electron-density of the porphyrin, resulting from the substituted chlorine group.[18]

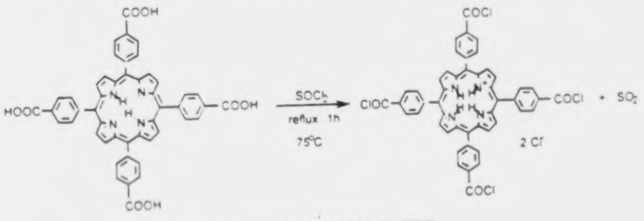

Figure 5. Synthesis of $H_2TClCPP$

Chitosan showed poor solubility in most common solvents, possibly due to the high degree of ordering through hydrogen-bonding interactions.[4] The polymer solubilized well in dilute acetic acid (10-20% v/v) via protonation of the oxygen and nitrogen centers to form a viscous gel. The structure of the gel was first investigated by ^1H nmr in a mixture of 10% CD_3COOD in D_2O. The polymeric nature of the material accounted for the broad signals (10.44, 10.25, 9.71 ppm) at 300K. A well-defined triplet at 8.58 ppm was assigned to the methylene proton at the C-5 position in the glucosamine moiety. Since the medium was acidic, peaks were shifted downfield of predicted chemical shifts. The amino protons were possibly also exchanging with solvent deteriums. These phenomena confounded further spectral analysis.

Preliminary experiments were performed in the preparation of chitosan films. First, chitosan flakes were dissolved in dilute acetic acid and produced a pale yellow, transparent gel. The gel viscosity increased as a function of time. Attempts at characterizing gels by FTIR were complicated by the strong carboxyl group vibrations of the acetic acid solvent. A petri dish served as the surface for casting and the gel was smeared on the surface with a glass rod after pipetting. After sitting overnight, the dry film was subjected towashings with dilute NaOH and water to neutralize the acetic acid solvent and to loosen the film from the surface. Non-fragile films produced on drying overnight were easily peeled from the glass surface. The materials were transparent with a pale yellow hue and were quite malleable. Films containing free base H_2TPP were pale blue in color. This method undoubtedly produces films of variable thickness. Experiments are underway to produce thin, uniform films. Future investigations involve characterization of the porphyrin-doped films by STM and AFM.

CONCLUSIONS

A new class of films has been prepared from chitosan, a cheap, abundant biomaterial. The porphyrins incorporated into the polymer matrix were synthesized by the condensation of pyrrole and aldehydes using two different synthetic routes. Spectroscopic techniques were utilized in the characterization of porphyrins and chitosan. The novel porphyrin thin films were pale blue, transparent, and relatively non-fragile. H_2TCPP was unreactive with chitosan. Therefore, the acid chloride derivative was prepared for reactivity with chitosan.

Dr. Kelly Keenan

The goal of the project is biochemical characterization of possible vacuolar mutants in *Neurospora crassa*. It was expected that mutation in any or all the vacuolar amino acid permeases and/or the vacuolar ATPase would result in a decreased level of vacuolar transport. Uptake of arginine, lysine, and ornithine was measured in these putative vacuolar mutants using a cupric ion permeabilization system. A preliminary test was done to ensure that cupric ion permeabilization system was valid in the mutant strains. Amino acid uptake was measured using radiolabelled amino acids for arginine, ornithine and lysine. Results were compared to wild type. Cupric ion permeabilization method was shown to be valid for mutants. Four mutants showed a reduced uptake for all three basic amino acids while two of them had reduced uptake for only one amino acid.

INTRODUCTION

It is easier to understand the multitude of diverse functions associated with more complex eukaryotic organisms by studying simpler eukaryotic organisms. The filamentous fungus used in this study was *Neurospora crassa*, commonly known as pink bread mold. There are many reasons *N. crassa* is commonly favored in biochemical and genetic experiments. The information derived from studying this fungus can be extrapolated to more complex organisms such as mammalian cells. The growth medium used is inexpensive, simple and easy to prepare. The generation time is relatively short. Mutation protocols are well established.

The main interest of this study is the fungal vacuole. Its functions have not been completely elucidated (Klionsky *et al.*, 1990). It has been determined that 98% of the total soluble pools of basic amino acids, ornithine, lysine, and arginine are stored in the vacuole, which only accounts for approximately 10% of the total volume of the cell. Movement of these amino acids into the vacuole goes against a concentration gradient. Hence, the process of storing these basic amino acids in the vacuole is energetically expensive (Davis, 1986). An energy source is required to facilitate the transport of these basic amino acids into the vacuole. This process is accomplished by the vacuolar ATPase by hydrolysis of ATP.

Three different amino acid vacuolar permeases have been characterized that transport ornithine, lysine and arginine into the vacuole. The arginine specific permease selectively transports arginine only (Zerez *et al.*, 1986). Lysine uptake into the vacuole is not inhibited by ornithine and ornithine uptake is not inhibited by lysine. This suggests distinct permeases for these amino acids, yet the specificity of these has not been completely characterized.

One method for characterizing vacuolar amino acid permeases is to create a mutant strain that lacks permease activity or activities. Previous experiments have isolated such mutants. It was expected that a failure to transport one (or more) of the basic amino acids into the vacuole in a strain would result in increased cytosolic concentration of the amino acid, and this would be toxic. Mutants show increased sensitivity to one or more of the basic amino acids as well as a decreased ability to accumulate the amino acids in the vacuole.

A direct way to determine if these mutants are vacuolar permease mutants is to measure the vacuolar uptake of the basic amino acids. A cupric ion permeabilization system has been developed for wild type *Neurospora crassa* that selectively permeabilizes the plasma membrane but leaves the vacuole intact. Cupric ion permeabilized mycelia are used for measuring vacuolar basic amino acid permease activity. To ensure that the permeabilization of the cupric ion on the mutants is similar to that of wild type, preliminary tests were performed by assaying for the intracellular enzyme, ornithine transcarbamylase (OTC), by means of the OTC assay.

There is evidence that the addition of cupric ion causes a selective change in the permeability of the plasma membrane but leaves the vacuolar membrane intact (Ohsumi *et al.*, 1988). This observation provides an effective method of separating the cytosolic and vacuolar constituents. The vacuolar permease activity can therefore be effectively measured.

The effects of cupric ion permeabilization on the potential mutants and the wild type were studied and compared to determine the effectiveness of the procedure. Basic amino acid uptake into vacuole was measured in putative mutant strains using cupric ion-permeabilized mycelia. Uptake was compared to wild type to identify those with deficient permease activity.

METHODOLOGY

Cupric Ion Permeabilization

Putative vacuolar mutants were grown and inoculated in Vogel's minimal media with 1.5% sucrose. They were allowed to grow overnight at 16°C and then for 4-6 hours at 30°C in a shaking water bath. Mycelia were collected by centrifugation and washed with distilled water. Unless stated otherwise, all centrifugations were done in a table top centrifuge at maximum speed (1,000xg) for 3 minutes. The pellets were suspended in a uptake buffer (UB = 0.6 M sorbitol, 20 mM morphinolinoethane sulfonic acid/Tris, pH 6.0), and divided into two aliquots. To one portion, 4mM Cu^{+2} was added from 100 mM $CuCl_2$ while other was untreated. Both aliquots were placed in a shaking water bath for 20 minutes, collected by centrifugation, and washed twice with UB. Each portion was re-suspended in buffer and further divided in half. A volume of 1.0 ml was removed to assay for protein using the Lowry assay. To one portion the detergent Triton X-100 was added to a concentration of 1%. There were four samples: cupric treated with and without Triton X-100 as well as untreated with and without Triton X-100. Each fraction was assayed for ornithine transcarbamylase activity (Keenan).

Vacuolar Amino Acid Uptake

Mycelia were grown, collected, washed, and suspended as described. For cupric ion permeabilization, cupric ion was added to 4mM concentration from 100 mM $CuCl_2$ solution and mycelia were shaken on a water bath for 20 minutes at 30°C. Permeabilized mycelia were collected by centrifugation, washed twice with UB and re-suspended in UB. A portion is removed for protein analysis by Lowry procedure. To initiate the uptake assay, ^{14}C-Arginine, ^{3}H-Lysine or ^{3}H-Ornithine were added and mycelia were shaken at 30°C. At 0, 5, 10, 15, 20, and 40 minutes, samples were removed, filtered through Whatman GF/A filters, washed with ice cold UB and suspended in distilled water. A boiling water extraction was done followed by a centrifugation. A portion of the supernatant was removed, mixed with scintillation fluid and level of radioactive material is measured in a liquid scintillation counter.

DATA AND RESULTS

In order to determine if cupric ion permeabilizes membranes of mutant strains, OTC activity was measured in mycelia treated and untreated with cupric ion.

Table 1: Ornithine Transcarbamylase (OTC) specific activity

STRAIN	Specific Activity			
	w/ Cu+2 & 1% Triton (nmole/mg min)	Cu+2 treated only (nmole/mg min)	1% Triton treated only (nmole/mg min)	in AUB only (nmole/mg min)
74A	0.11	0.10	0.11	0.02
RSC-41	0.09	0.12	0.11	0.00
RSC-53	0.02	0.16	0.32	0.35
RSC-57	0.09	0.07	0.09	0.02
RSC-66	0.06	0.06	0.05	0.01
RSC-85	0.05	0.01	0.03	0.00

BEST COPY AVAILABLE

Since Triton X-100 is a detergent, it completely solubilizes all membranes. In mycelia treated only with Triton X-100, the specific activity of the ornithine transcarbamylase enzyme is 0.11 nmol/mg min for wild type as shown in Table 1. The activities of the extracts treated with cupric ion alone and with Triton X-100 are similar, 0.11 and 0.10 nmol/mg min, respectively. Table 1 also shows that in the presence of buffer only, the OTC specific activity was 0.02 nmol/mg min. The membrane in this extract remained intact. These results suggest that cupric ion has the same effect as Triton X-100. Furthermore, data for the mutants RSC-41, RSC-57, and RSC-66 exhibit the same pattern of OTC activity as the wild type. This suggests that cupric ion selectively permeabilizes the plasma membrane of both the mutants and the wild type similarly.

Since it was shown that cupric ion permeabilizes the plasma membrane in mycelia, vacuolar amino acid uptake was measured. Uptake was measured over time as shown in Figure 1. Uptake increased linearly until 15 minutes and initial velocity was calculated based on the first three points.

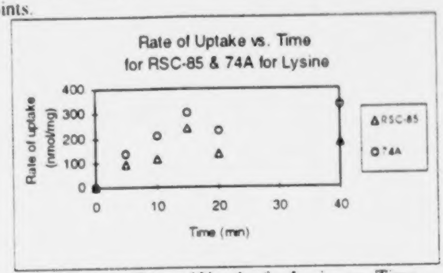

Figure 1: Rate of Uptake for Lysine vs. Time

In order to determine if the strains had a reduced level of vacuolar uptake from the wild type, a range for wild type was calculated using average +/- standard deviation. A strain is considered to have reduced vacuolar uptake if the value falls below the range of the wild type. The results for the vacuolar uptake of all three amino acids is shown in Table 2.

Table 2: Rate of Basic Amino Acid Uptake in Putative Vacuolar Mutants

Strains	Rate of Uptake		
	Lys (nmol/mgxmin)	Arg (nmol/mgxmin)	Orn (nmol/mgxmin)
74A Mean	4.34 *(+/-) 1.73*	5.80 *(+/-) 3.20*	14.04 *(+/-) 5.19*
RSC-57	2.76	3.09	1.30
RSC-41	0.67	1.68	0.79
RSC-66	0.24	1.24	1.23
RSC-53	0.56	0.74	N/A
RSC-85	3.02	6.10	0.98
RSC-87	[illegible]60	0.14	1.22

RSC-57 and RSC-85 appear to have a lower rate of uptake of ornithine as compared to wild type yet arginine and lysine uptake values are within range of wild type. RSC-57 and RSC-85 have a reduced level of ornithine uptake while lysine and arginine uptake are normal. RSC-41, RSC-53, RSC-66, and RSC-87 have lower rates of uptake of arginine, lysine, and ornithine.

DISCUSSION

The putative vacuolar permease mutants of *Neurospora crassa* were biochemically characterized. RSC-85 and RSC-57 are possible ornithine vacuolar permease mutants. The other mutants, RSC-41, RSC-53, RSC-66, and RSC-87, have a decreased ability in transporting all three basic amino acids, arginine, lysine, and ornithine, into the vacuole. They are potential vacuolar ATPase mutants.

The treatment of mycelia with cupric ion was successful in selectively permeabilizing the plasma membrane of both the mutants and the wild type. This allowed for the selective analysis of the rate of uptake of vacuolar permeases.

Future studies include the measurement of vacuolar ATPase activity for strains that appear to be vacuolar ATPase mutants as well as genetic characterization using complementation analyses.

ACKNOWLEDGMENTS

The authors wish to express their appreciation and thanks to Dr. Kelly Keenan for her guidance and unending support throughout the course of this research. Furthermore, the authors would like to acknowledge Mr. Christopher Utzat for performing the preliminary research on the uptake of basic amino acids on the wild type 74A.

Preparation of Co(PYAN)$^{+3}$ and Progress Toward the Separation of its Optical Isomers

Lori Bigler

Seattle, WA 98122

Faculty Advisor

Susan C. Jackels

[Co(en)$_3$]$^{+3}$ is a classical complex having D$_3$ symmetry for which the optical isomers have been separated and much is known about the electronic and circular dichromism spectra. This research involves the preparation of [Co(PYAN)]$^{+3}$, a complex somewhat similar to [Co(en)$_3$]$^{+3}$ but having D$_2$ symmetry. In [Co(PYAN)]$^{+3}$ the hexaaza macrocycle, pyo$_2$[18]dieneN$_6$, or PYAN, is complexed with Co(III). The complex is prepared from sodium tris (carbanato)- cobaltate(III) trihydrate reacted with PYAN•4HBr and is precipitated out of absolute ethanol as a bromide salt, [Co(PYAN)]Br$_3$.

INTRODUCTION

Co(II) and Co (III) both form stable coordination complexes. Once in complex form, Co(II) is commonly oxidized to Co(III) to produce a more stable and less labile Co(III) complex. This research involves complexing Co(III) directly to form a stable complex by ligating with 3,6,14,17,23,24-hexaazatricyclo[17.3.1.1]tetracosa-1(23),8,10,12(24),19,21-haxaene, or PYAN (Figure 1, below.)

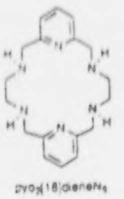

Figure 1. PYAN

PYAN is an 18-membered ring having D$_2$ symmetry, with one two-fold axis through the pyridine rings, two C$_2$ axes perpendicular, and no horizontal or vertical planes of symmetry. When PYAN is complexed with a metal ion, the molecule, due to rigidity and planarity imposed on it by the pyridine rings, wraps only in the meridional mode and retains D_2 symmetry. Of the five possible isomers[1] of PYAN shown in Figure 2 only one is known to occur in coordinated form.

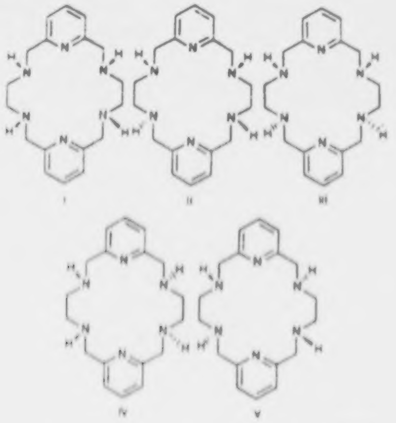

Figure 2. Five possible isomers of PYAN

The isomer (V) forms optically active stereoisomers with the RR,RR isomer twisting left, producing the Δ enantiomer, and the SS,SS isomer twisting right, producing the Λ enantiomer as shown in Figure 3.

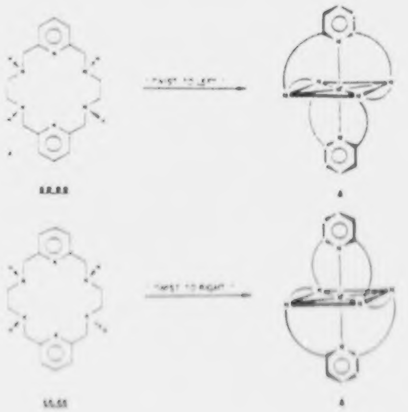

Figure 3. Enantiomeric twist of coordinated PYAN

Previous separation attempts[2] of these optical isomers yielded inconclusive results. The racemic mixture was treated with the optically active compound potassium antimonyl-*d*-tartrate which theoretically reacts with these enantiomers to form diastereomeric salts. No separation was evident from these results and it is thought that all of the Co(PYAN) was precipitated out under the conditions tried. This research will attempt separation of the racemic mixture by eluting through an ion exchange column with an optically active eluent, sodium-*d*-tartrate This technique was successfully applied by Yoshikawa et al[3] to $[Co(en)_3]^{+3}$ and resulted in complete resolution

EXPERIMENTAL PROCEDURE

PYAN was synthesized starting with 2,6-pyridinedicarboxylic acid purchased from Aldrich Chemical Co The procedure involved first esterification of the white powder, then reduction to 2,6-pyridinedimethanol, and finally oxidation to 2,6-pyridinedicarbaldehyde, by previously published methods[4] The 2,6-pyridinedicarbaldehyde was then combined with ethylenediamine to produce the Schiff base cyclized tetraimine intermediate (shown below) which was further reduced with $NaBH_4$ to give PYAN The free base was converted to the bromide salt by protonating with HBr in methanol The complex with Co(III) was prepared by reacting PYAN•4HBr with $Na_3[Co(CO_3)_3]\bullet 3H_2O$ as shown in Figure 4 below

RESULTS

Elemental analysis, infrared spectra and magnetic susceptibility tests were all used to confirm the product The results of the elemental analysis are summarized in Table 1

BEST COPY AVAILABLE

Table 1 Elemental analysis results for [Co(PYAN)]Br_3

Element	Calculated %	Experimental %
Carbon	34.59	34.76
Hydrogen	4.19	4.40
Nitrogen	13.50	13.67
Cobalt	9.43	9.82

IR spectra of a previously synthesized [Co(PYAN)]Br_3 complex were available for comparison. The peaks indicative of the product are readily seen in the spectra of the newly prepared compound and are summarized in Table 2 below.

Table 2 Infrared spectra results

IR Peak (cm^{-1})	Assignment
3132.8	N-H stretch
2996.4	C-H aromatic
1608.2	C=N stretch (pyridine)
1482.1	aromatic ring
1459.2	aromatic ring

Magnetic susceptibility tests run on the product confirmed the presence of Co^{3+}. The results indicated that the compound is diamagnetic, and that the metal is in the +3 oxidation state and low spin state. In this case, the electron configuration for Co^{3+} will correspond to t_{2g}^6 (octahedral). Had the metal been reduced to Co^{2+} the product would have been paramagnetic.

Optical resolution of the stereoisomers is being attempted by ion exchange column chromatography. Sephadex C25 was obtained from Aldrich and the ion exchange column has been set up for the separation process according to the procedure by Yoshikawa *et al*.[4] The column was packed with Sephadex C25 and a 0.2 M solution of sodium-*d*-tartrate was prepared for use as eluent. The ion exchange process has run for a total elapsed time of 15 hours, with no apparent results to date, although the yellow band containing the sample has slowly moved down the column. As the sample elutes it will be collected for further testing.

A small amount of [Co(PYAN)]Br_3 (0.001g) was dissolved in 2 mL water and its absorbance recorded using a Hewlett-Packard Photo Diode Array. The following table shows the wavelengths and corresponding absorbance bands.

Table 3 Absorbance spectra for [Co(PYAN)]Br_3

Wavelength (nm)	Absorbance
244	2.9437
254	2.8115
448	0.19821

The spectra will be used to determine which fractions collected from the column contain the appropriate material for further testing. If two separated bands are observed, each will be pooled and concentrated. A second ion exchange column will remove the optically active sodium-*d*-

BEST COPY AVAILABLE

tartrate and replace it with bromide. The resultant bromide salt is non-optically active and will not affect the optical rotatory ability of the Co(III) complex. Polarimetry will ultimately ascertain if the separation was successful.

ACKNOWLEDGMENTS

In recent years many marine pyridoacridine alkaloids have been isolated from tunicates, sponges and a type of anemone. These compounds have drawn special attention due to their pharmaco-biological activity. After studying their chemical structure and biological properties, we have proposed that the identification and synthesis of biological active precursors of some marine alkaloids could be possible. In this study we report our attempts at the synthesis of 6-Methylthiazin-3-one-(5,6-b)-acridine-5,12-dione(Fig. 3) which is a precursor and probable pharmacophore of shermilamine B (Fig. 2).

INTRODUCTION

There is current interest in marine pyridoacridine alkaloids because of their significant properties. Amphimedine was the first marine alkaloid described in 1983 by two research groups led by Schmitz and Shoolery.[1] Today, we find a considerable number of descriptions of these types of compounds in the literature. These novel compounds have in common a fused tetracyclic pyrido (2,3,4-mn) acridine ring system (Fig. 1).[2] They have been isolated from diverse marine organisms including sponges, tunicates, and a type of anemone.[1] Therefore, it is very interesting that pyridoacridine alkaloids present an unprecedented distribution among several phyla of marine invertebrates.[1]

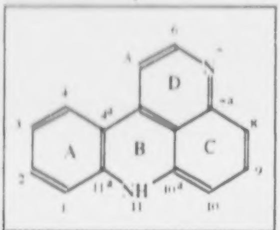

Figure 1: Structure of the fused tetracyclic pyrido (2.3.4-mn) acridine ring system

Reports indicate that most pyridoacridine alkaloids are cytotoxic to a variety of cancer cell lines[3,4], and they also show antineoplasic activity in whole animal experiments.[1] The mechanism by which they act is not yet clear, and it is unknown whether they act via the same mechanism.[2] It is also unknown if these compounds are only cytotoxic agents or if they are growth regulators as well.[2] Even though there is still a lot to learn about the marine alkaloids, some specific biological properties have been reported for different compounds. For example, inhibition of topoisomerase II catalytic activity,[5] anti-HIV activity,[6] Calcium release activity, intercalation of DNA,[8] DNA single-strand cleavage,[1] and alteration of cAMP-mediated processes and/or other second messenger systems.[2]

Among the biologically active marine alkaloids are shermilamine A, shermilamine B, amphimedine, ascidemine, kuanoniamine, bromoleptoclinidinone, dercitin, nordercitin, cystoditin A and cystoditin B.[1,3] We proposed that the identification and synthesis of biologically active precursors of some marine alkaloids would be possible. In this study we attempted the synthesis of 6-Methylthiazin-3-one-(5,6-b)-acridine-5,12-dione (fig. 3), a precursor and probable pharmacophore of shermilamine B (fig. 2) following a scheme that contains a series of well known reactions.[9,11]

BEST COPY AVAILABLE

Pentacyclic pyridoacridine alkaloids are classified into two groups: those having a linear ring fusion at C 8, 9 of ring C, and those having one extra angular fused ring at C 9,10 of the acridine system at ring C. Shermilamine B (Fig. 2) is a naturally occurring pentacyclic pyridoacridine that belongs to the former group, and has been found in the colonial tunicate *Trididemnum*. Its molecular formula is $C_{21}H_{18}N_4OS$ and it has been reported to have a mp. of 234 °C.[12,13] 6-Methylthiazin-3-one-(5,6-b)-acridine-5,12-dione (fig. 3) is a tetracyclic compound that has not been previously isolated or synthesized. Therefore, there is no information available on its biological activity and physical properties.

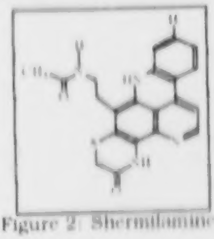

Figure 2: Shermilamine B

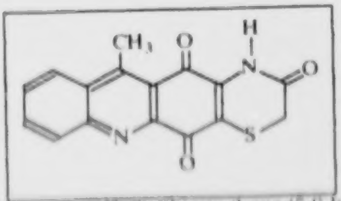

Figure 3: 6-Methylthiazin-3-one-(5,6-b)-acridine-5,12-dione

METHODS/RESULTS

The synthesis of 6-Methylthiazin-3-one-(5,6-b)-acridine-5,12-dione (fig. 2) was attempted by the following scheme, statrting with readily available 2,5-Dimethoxyaniline (fig. 4). The ^1H-NMR data was obtained on a 200 MHz Bruker instrument and the IR data on a Perkin Elmer Infrared Spectrophotometer 735B. In order to obtain compound (4), 2,5 dimethoxyacetanilide, three different sets of reactions (a), (a'), and (a'') were performed.

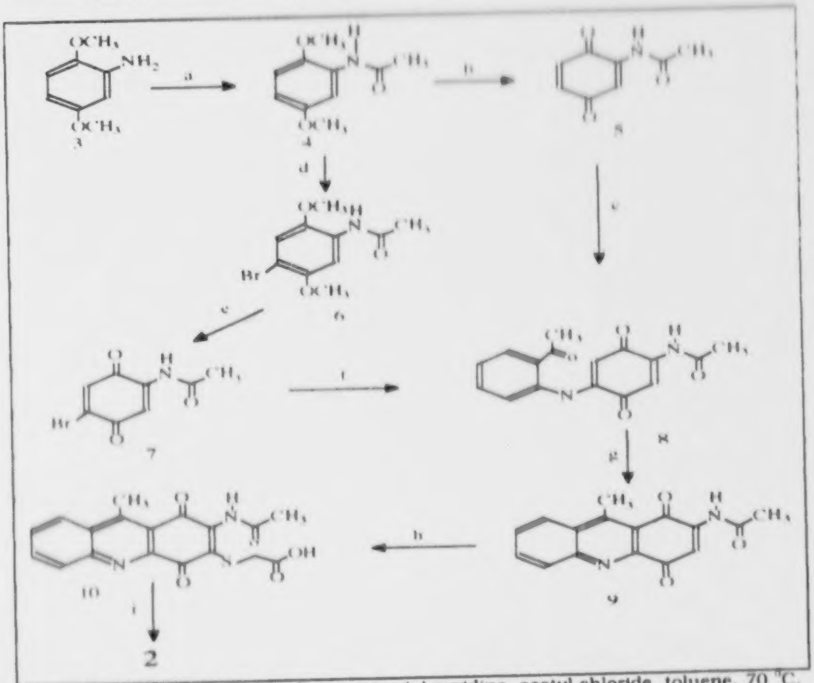

Figure 4: Synthetic Scheme. Reagents: (a) pyridine, acetyl chloride, toluene, 70 °C, 1 hr. (a') conc. HCl, Sodium acetate, acetic anhydride, 50 °C, 1 hr. approx. (a'') pyridine, acetic anhydride, 1M HCl, rt, 24 hr. (b) CAN, CH_3CN-H_2O, 2M H_2SO_4 0-5 °C. (c) 2-aminoacetophenone, cerric chloride heptahydrate, rt, 24 hrs. (d) bromine, acetic acid, rt, 24 hrs.

(a). 2,5-Dimethoxyacetanilide (4). Dry pyridine (5 mL) and acetyl chloride (1.28 g,1.16 mL,16.4 mmol) were added to a solution of 2,5 dimethoxyaniline (3) (1.0 g,6.6 mmol) in 20 mL of dry toluene. The solution was heated (70 °C, 1 hr.). The mixture was cooled to room temperature and then poured into water (600 mL). The aqueous layer was extracted with toluene (3X35 mL). The combined toluene solution was dried with anhydrous sodium sulfate, filtered, and the toluene was removed on the rotary evaporator. Ethyl acetate (80 mL) was added to the residue. The solution was then washed with 1M HCl (3x25 mL) and later dried over anhydrous sodium sulfate. The resulting material was compared with the starting material by TLC. The product was purified by flash chromatography on SiO_2 with the eluant being dichloromethane. NMR studies confirmed the presence of the compound 4. 0.96 g (75.5%) of purified product was obtained.

(a') 2,5-Dimethoxyacetanilide (4). Concentrated HCl (30 mL) was added with stirring to water (60 mL). Compound 3 (3.0g,19.6 mmol) was added to this solution. The solution was decolorized with decolorizing charcoal and then filtered off. Sodium acetate (4.5 g) was dissolved in water (12 mL). The anilinum solution was warmed to 50 °C on a water bath. Acetic anhydride (4 mL) was added with stirring. The aqueous sodium acetate was added on dissolution of the acetic anhydride. The mixture was stirred and cooled in an ice bath. No crystals of amide were obtained. The aqueous solution was extracted with dichloromethane (3X25 mL) and dried over anhydrous calcium chloride. The solvent was removed and a purple-brownish oil was obtained. The product was purified by flash chromatography on SiO_2 using a 15% ethyl acetate/dichloromethane mixture as the eluant. A sample of the purified material was submitted for IR-spectra studies which showed the presence of the carbonyl functionality indicative of compound 4. The yield of the reaction was 2.0 grams (52.3 %)of compound 4.

(a'') 2,5-Dimethoxyacetanilide (4). Compound 3 (3.5 g, 23 mmol) was dissolved in dry pyridine (10 mL), and dry acetic anhydride (5.4 mL, 5.9 g, 58 mmol) was added to this solution. The solution was stirred for 24 hrs. Water (50 mL) was added to the mixture, and the whole extracted with ethyl acetate (4X50 mL) in a separatory funnel. The aqueous solution was extracted. The ethyl acetate layer was washed with 1M HCl (3X40 mL) and with brine (3X40 mL). The solution was then dried with anhydrous sodium sulfate. The reaction mixture was filtered and the solvent removed. The final product was a brown crystallized material. NMR studies confirmed its presence in a pure form. Finally, 4.40 g.(95.2%) of material were obtained.

(b). 2-Acetamido-1,4-benzoquinone (5). Compound 4 (2.0 g, 10.2 mmol) was stirred in acetonitrile (10 mL). Ceric ammonium nitrate (CAN)(8.43 g, 15.38 mmol) at 0-5 °C dissolved in 2M H_2SO_4 (25 mL) was added portionwise with stirring. The reaction was monitored by TLC at 2 and 4 hr. At 4 hr. the reaction was complete. The TLC showed presence of some by-products. The products were separated by flash chromatography on SiO_2 using 50% ethyl acetate/chloroform as the eluant. 0.76 g (45.8%) of the compound 5 in the form of a black powder was obtained. The NMR results confirmed the presence of the compound.

c. 2-Acetamido-5-acetilanilino-1,4-benzoquinone (8). A solution of compound 5 (92 mg, 0.56 mmol) in ethanol (15 mL) was added to a solution of 2-aminoacetophenone (83 mg, 0.616 mmol) and cerric chloride heptahydrate (230 mg) in ethanol (15 mL). The reaction was stirred overnight. The products of the reaction were purified by flash chromatography on SiO_2 using a 50% ethyl acetate:chloroform mixture as the eluant. The yield of the reaction was 70.9% and the NMR data confirmed the presence of compound 8.

d. 4-Bromo- 2,5-dimethoxyacetanilide (6). Bromination of (4) to (6) was tried using bromine in acetic acid. To a solution of compound 4 (3.0 g, 15.4 mmol) in acetic acid (50 mL) , a solution of bromine (1.0 mL, 2.6 g, 16 mmol) in acetic acid was added at 5 °C. The resulting mixture was stirred at room temperature overnight. The solution was poured in cold water (200 mL) and stirred for 5 more min. Sodium bisulfate solution (50%) was added dropwise until the bromine color was discharged. The mixture was cooled in an ice-bath for 30 min. and the product was collected by vacuum filtration. This reaction proved to be very slow, and after more than 24 hr., starting material was present along with a mixture of products. No attempt to characterize the products of this reaction was made.

DISCUSSION

We performed three reaction procedures in an effort to obtain compound 4 from compound 3. This was done so that we could compare methods and identify the most efficient in terms of yield and purity of the products. In reaction (a), we acylated the 2,5-dimethoxyaniline (3) in dry toluene in the presence of dry pyridine and by addition of acetyl chloride. The pyridine reacted with the liberated HCl converting it into a pyridinium chloride salt. We obtained a % yield of 75.5 of the acylated amine.

In reaction (a'), we obtained compound 4 by reaction of compound 3 with sodium acetate and acetic anhydride in presence of HCl. This reaction presented the lowest percentage yield of the three methods.

Reaction (a''), where compound 3 is stirred in dry pyridine with acetic anhydride, proved to be a very simple and efficient method to carry out the transformation of compound 3 to compound 4. The reaction had a 95.2% yield after purification of the final product (4).

Reaction (b) was the oxidation of compound 4 to obtain the respective benzoquinone (5). In the review of the literature, we found that ceric ammonium nitrate [Ce $(NH_4)_2(NO_3)_6$, CAN] in aqueous acetonitrile oxidizes a variety of 2,5-disubstituded 1,4-dimethoxy benzene derivatives yielding the p-benzoquinones.[14] So, we performed the reaction following this method The yield was 45.8% after purification. A review of the literature led us to believe that this reaction may have been complicated by competitive dimerization. We believe that the yield of this reaction can be improved by using pyridine-2,6-dicarboxylic acid-N-oxide reducing the polymerization of the benzene compounds.

Reaction (d), in which the bromination of compound 4 was attempted to obtain 4-bromo-2,5-dimithoxyacetanilide (6), was inconclusive. This reaction proved to be very slow, and after more than 24 hr. starting material was present along with a mixture of products. No attempt to characterize the products of this reaction was made.

In reaction (c), compound 8 was synthesized by reacting compound 5 in ethanol with a solution of 2-aminoacetophenone and cerrous chloride heptahydrate. The reaction was efficient (70.9% yield) and the compound was successfully isolated with high purity.

CONCLUSIONS

Marine pyridoacridine alkaloids are a novel class of compounds that present an interesting chemical configuration and have come to occupy a primary position in the biomedical field as powerful antitumor agents or lead compounds. There is still much to learn about their chemical, physical, and biological properties. Therefore, if in the near future we are successful in designing efficient synthetic strategies for the pyridoacridine alkaloids, it would be of crucial importance for the understanding of their chemical characteristics and biological actions. To date, we have not been able to carry out our proposed synthetic scheme to completion. However, the results obtained so far indicate that the synthesis of 6-methylthyazin-3-one-(5,6-b)-acridine-5,12-dione(2) could be achieved following our proposed scheme. The results of the final part of this synthesis are pending.

Vanadium (V) compounds, such as $NaVO_3$, exert potent toxic effects on a wide variety of biological systems and some mechanism proposed that vanadate-mediated hydroxyl radical generation is a possible step in these toxic reactions. Also, V(V) is responsible for the stimulation of NAD(P)H and NADH oxidation in biological membranes and the mechanism is controversial. Some reports favor a key role of superoxide ($O_2^{\cdot -}$), while others suggest enzymatic pathways, independent of $O_2^{\cdot -}$, where vanadium (IV) accumulates in a buffered V(V), cofactor and enzyme solution. The V(IV) species depend critically on the simultaneous presence of enzyme and cofactor. The controversial mechanism has two opposite viewpoints and the purpose of this research is to determine the most reasonable mechanism according to the observations of V(IV) accumulation by ESR, NAD(P)H and NADH oxidation kinetics and oxygen consumption determinations.

INTRODUCTION

Vanadium (V) species, such as $NaVO_3$, exhibit potent toxicity on a wide variety of biological systems. The biochemical mechanism which explains V(V) toxicity is still not well understood. Vanadate-mediated hydroxyl radical ($HO^\cdot$) generation is assumed to be a possible step in these toxic reactions. Also, V(V) has repeatedly been responsible of the stimulation of the reduced forms of Nicotinamide Adenine Dinucleotide Phosphate (NAD(P)H) and Nicotinamide Adenine Dinucleotide (NADH) oxidation in biological membranes and the biochemical mechanism is very controversial.

Liochev and Fridovich (Liochev, S. & I. Fridovich, 1990) favor that superoxide radical ($O_2^{\cdot -}$) plays a key role in the mechanism, where a radical chain reaction in which the peroxovanadyl V^{+4}-O-O$^\cdot$ is formed has been proposed. They reported molecular oxygen (O_2) consumption and the accumulation of hydrogen peroxide (H_2O_2). Also, superoxide dismutase (SOD) completely inhibited the V(V) effect, whereas catalase exerted no inhibition in phosphate as well as in 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (Hepes) buffered solutions.

On the other hand, Shi and Dalal (Shi, X. & N. Dalal, 1991) suggest enzymatic pathways, independent of $O_2^{\cdot -}$ but dependent on molecular oxygen (O_2), where V(IV) accumulates in a buffered V(V), cofactor and enzyme solution. According to this, the V(IV) accumulation was found to take place in the presence of enzyme and cofactor simultaneously. In 1991, they encountered no SOD inhibition on the NAD(P)H or NADH oxidation, concluding that $O_2^{\cdot -}$ had no role in the enzyme-catalyzed NAD(P)H or NADH oxidation by V(V). Also, Shi and Dalal presented that the H_2O_2 generated in the enzymatic mechanism reacts with V(IV) to produce $HO^\cdot$ in a Fenton-like reaction ($Fe^{+2} + H_2O_2 - Fe^{+3} + HO^\cdot + HO^-$), not in a Haber-Weiss-like reaction ($O_2^{\cdot -} - H_2O_2 \rightarrow O_2 + HO^\cdot + HO^-$).

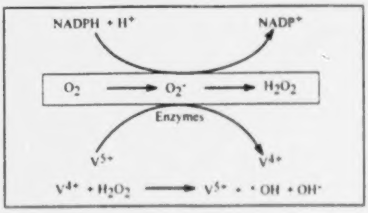
Furthermore, in 1993 they proposed a mechanism based on a free radical chain reaction instead of an enzymatic pathway (Shi, X. & N. Dalal, 1993). It was because of the observations involving a non-linear increase with time of the V(IV) concentration, as it was supposed to be in an enzyme-mediated mechanism. Both mechanisms could be summarized in the following equations:

Mechanism proposed by Liochev and Fridovich:

$$V^{+5} + O_2^{\cdot-} \rightarrow V^{+4}\text{-O-O}^{\cdot}\ (1)$$
$$V^{+4}\text{-O-O}^{\cdot} + \text{NAD(P)H} \rightarrow V^{+4}\text{-O-OH} + \text{NADP}^{\cdot}\ (2)$$
$$V^{+4}\text{-O-OH} + H^{+} \rightarrow V^{+5} + H_2O_2\ (3)$$
$$\text{NADP}^{\cdot} + O_2 \rightarrow \text{NADP}^{+} + O_2^{\cdot-}\ (4)$$

Net reaction: $\text{NAD(P)H} + O_2 + H^{+} \rightarrow \text{NADP}^{+} + H_2O_2$ (5)

Mechanism proposed by Shi and Dalal:



V(IV) accumulation may be monitored by Electron Spin Resonance spectrometry and oxygen consumption determinations are done using Clarke electrode polarography in order to determine $O_2^{\cdot-}$ role in the mechanism. Also, it is essential to follow NAD(P)H or NADH oxidation by observing the decrease in absorbance as a function of time at λ=340nm.

OBJECTIVE

Establish if the mechanism responsible for the NAD(P)H or NADH stimulated oxidation by Vanadium (V) is either:

1. a radical chain reaction
2. an enzymatic pathway
3. a Fenton-like or a Haber-Weiss-like reaction

The effect of SOD and Catalase upon this reactions will be monitored to identify the most adequate mechanism.

TABLE I: Table of Reagents

Reagents		ESR experiments		UV-Vis experiments	
		Stock Concentration	Assay Concentration	Stock Concentration	Assay Concentration
Vanadate (Sigma)	Sodium Metavanadate ($NaVO_3$)	50 mM	4.8mM- XO 2.5mM- GSSG-R	50 mM	0.2 mM
Cofactors (Sigma)	NADH	10 mM	2.0 mM	50 mM	0.2 mM
	NAD(P)H	10 mM	2.5 mM	50 mM	0.2 mM
	Xanthine (X)	2.0mM	0.3 mM	2.0 mM	0.14 mM
Enzymes (Boehringer Mannheim)	Xanthine Oxidase (XO) (Sigma)	31 u/mL	0.1 u/mL	26041 µg/mL	50 µg/mL
	Glutathione Reductase (GSSG-R)	600 u/mL	15 u/mL	5000 µg/mL	50 µg/mL
	Superoxide Dismutase (SOD)	5000 u/mg	100 u/mL	1000 µg/mL	1 µg/mL
	Catalase	65000 u/mg	5000 u/mL	20000 µg/mL	10 µg/mL

METHODOLOGY

A phosphate buffer monobasic (pH 7.4, from Fisher) is treated first with Chelex 100, using the dialysis method, in order to avoid any metal contamination. All solutions are freshly prepared using this buffer. Then they are mixed in the buffer, to a final volume of 1.5 mL to reach the target assay concentrations. ESR spectra are recorded, following this catalytic scheme:

Xanthine/Xanthine Oxidase System:

a. V + NADH + X + XO
b. V + X + XO
c. V + NADH + X
d. V + NADH + XO
e. a. + XO (boiled)
f. a. + SOD
g. a. + Catalase
h. V + X
I. V + NADH
j. V + XO

Glutathione Reductase System:

a. V + GSSG-R + NAD(P)H
b. V + GSSG-R
c. V + NAD(P)H
d. a. + GSSG-R (boiled)
e. a. + SOD
f. a. + Catalase

In the UV-Vis spectrophotometric experiments, the catalytic scheme described above is followed, but with the specific concentrations (see Table of Reagents). The measurement is done in a 1.000 cm cuvette and the reaction mixture is monitored each 15 seconds for 30 minutes at A_{340nm}. A kinetic plot is obtained and the reaction rate (dA/dt) is analyzed.

RESULTS AND DISCUSSION (data not shown)

ESR experiments

When all the components (xanthine oxidase, NADH, xanthine and vanadate) are added to the reaction mixture in the case of xanthine oxidase, we observed vanadyl accumulation. That is, the reaction proceeds in the presence of enzyme, cofactors and vanadate. If xanthine is not added, a weak signal is obtained suggesting that xanthine is not extremely necessary over NADH for the reduction of vanadate in the presence of xanthine oxidase. If the enzyme is not added, a poor signal to noise ratio is obtained also and it is even weaker than when xanthine is not present (previous sample). This implies the possibility of direct reaction between NADH and vanadate instead of the enzymatic process or pathway. Furthermore, when NADH is not in the reaction mixture, no vanadyl accumulation is observed, suggesting that the cofactor is important for the process to take place. The assay with boiled xanthine oxidase presents the same results that without the enzyme (weak vanadyl signal). The effect of SOD is clearly observed; since the process is completely inhibited in its presence implying that $O_2^{\cdot-}$ is playing an important role in the mechanism studied. Also, the effect of catalase confirms that as it reacts with H_2O_2, vanadyl accumulates with very high yield in the reaction mixture.

In the case of glutathione reductase we observed the same results, but in this system, the enzyme is essential. When GSSG-R is not added, the reaction does not take place, suggesting that in this system, the enzyme presence is extremely necessary. Again, SOD and catalase exert the same effect as in the xanthine oxidase system.

Oxygen consumption determinations

The reaction mixture of vanadate, NADH, xanthine and xanthine oxidase consumes oxygen in high proportion, however, if we mix the components except the enzyme, the assay does not consume oxygen until xanthine oxidase is added. The same happened with GSSG-R. A relatively high consumption is observed in the assay of NADH and vanadate (but not as sharp as in the presence of xanthine oxidase), suggesting that the reaction proceeds through a direct reaction between the metal and the cofactor. The oxygen consumption ratio of NADPH and vanadate is not as high as NADH but the direct reaction is still observed. The addition of SOD exhibits inhibition of the oxygen consumption process. SOD essentially stops the reaction (SOD assay in underway for the XO/X/NADH/V system). These results suggest that $O_2^{\cdot-}$ is essential for the reaction mechanism to proceed. Determinations with catalase have not been done for the moment.

Kinetic analysis

Kinetics of the oxidation of NADH and NADPH were measured at $\lambda = 340$nm. A plot of $-\Delta$ Absorbance vs time (in seconds) shows that the mixture of NADH, vanadate, xanthine and xanthine oxidase has a high rate, in contrast to both, the assay with NADH and vanadate and the assay with NADH, xanthine and vanadate. This suggest that the oxidation of NADH or NADPH proceeds rapidly in the presence of enzyme, and metal. The reaction among NADH, vanadate and xanthine oxidase in the absence of xanthine, has a considerable rate but not so high as the assay with xanthine. The same results are observed with the GSSG-R system. It may represent a synergistic effect of both cofactors in this system: xanthine vs NADH. So, the rates of reaction could be summarized as follow: $R_{mixture} > R_{\text{[illegible]}} > R_{\text{[illegible]}} > R_{\text{[illegible]}} > R_{\text{[illegible]}}$. Up to now, rate analysis of the effect of SOD has been performed from the xanthine oxidase system. The rate of reaction decreased by 3.69% but this has to be corroborated. It is important to point out that the enzyme is essential to observe any oxidation of the NADH or NADPH.

1576

CONCLUSION

The results observed may suggest an enzymatic pathway in which $O_2^{\cdot -}$ plays a significant role. The GSSG-R reacts with NADPH, reducing it to NADP•. NADP• reacts with O_2 to produce $O_2^{\cdot -}$. Then, the $O_2^{\cdot -}$ reduces vanadate to produce vanadyl and the $O_2^{\cdot -}$ is oxidized to H_2O_2. This component is known to react with vanadyl, reoxidazing it to vanadate and generating OH^- and OH• (Shi & Dalal, 1991). The presence of SOD in the system shows that it dismutases $O_2^{\cdot -}$ to O_2 and H_2O_2, inhibiting the reduction of vanadate to vanadyl, the oxygen consumption ($O_2 - O_2^{\cdot -}$) and slightly affecting the NADH oxidation rate. Furthermore, catalase reacts with the H_2O_2 produced by the $O_2^{\cdot -}$ oxidation preventing the reoxidation of vanadyl and allowing it to accumulate in the assay. Nevertheless, both systems may be different because GSSG-R is definitely essential for the process, whereas the xanthine/xanthine oxidase system the enzyme is not the most important factor to produce vanadyl or to consume oxygen. It is only in the absence of NADH that no vanadyl spectrum is obtained, implying the possibility of an oxidation-reduction reaction directly between the cofactor and the metal or between the cofactor and molecular oxygen. In the case of GSSG-R, if the enzyme or the cofactor are not added, no vanadyl ESR spectra is observed, ruling out a direct oxidation-reduction reaction between the cofactor and either the metal or oxygen.

More experimentations must be done in order to clarify which mechanism explains each system and to assure if each one has its unique pathway.

FUTURE PLANS

a. Changes in buffers
b. Kinetic control (Time control)
c. pH control
d. Aerobic versus anaerobic conditions

Möbius Kekulenes:
Semiempirical and *ab initio* Hartree-Fock Calculations of Their Structures and Properties

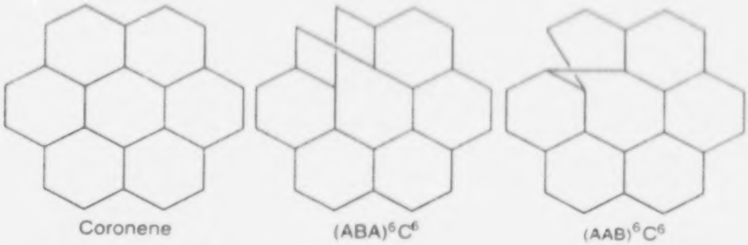
ABSTRACT

The structures and properties of the two possible coronene isomers, four possible Möbius-[12]kekulenes, and six possible Möbius-[18]kekulenes have been computationally investigated using the semiempirical PM3 method as well as by the *ab initio* Hartree Fock $3\text{-}23G^{(*)}$ method. These isomers each contain the half-twist which makes them one-sided and one-edged Möbius systems. In addition to discussions of their structures and electronic properties, information is presented regarding their potential for fluxional behavior as well as indications from vibrational analysis calculations concerning their possible structural interconversions.

INTRODUCTION

The methods by which coronene and coronoid molecules can be twisted into the topological equivalent of a Möbius band have been reported, and a descriptor system was presented which uniquely identifies the specific Möbius analogs of simple coronoids.[2] The two possible Möbius isomers of coronene were computationally investigated using the MNDO (modified neglect of diatomic overlap) semiempirical method. (See Figure 1).



Coronene

$(ABA)^6C^6$

$(AAB)^6C^6$

Figure 1. Coronene and its two Möbius isomers, $(ABA)^6C^6$ and $(AAB)^6C^6$. Double bonds and hydrogen atoms have been removed for clarity.

In continuing studies of the Möbius isomers of coronoid systems, semiempirical AM1 (Austin model 1) and PM3 (perturbational model 3) methods and the $3\text{-}23G^{(*)}$ *ab initio* method have been used to re-investigate the structures and properties of the Möbius isomers of coronene. Further, the work has been extended to include studies of the four Möbius isomers of [12]kekulene (Figure 2) and the six Möbius isomers of [18]kekulene (Figure 3) using the PM3 method. Computational results for each of the molecules are reported herein. Each Möbius isomer is identified by its individual character string as previously described.[1]

METHODS

All computations were carried out using the SPARTAN suite of programs[3] running on Silicon Graphics Indigo2 workstations. The initial geometries were constructed with the BUILDER module in SPARTAN, using the expert mode.

RESULTS

The tables below list the calculation results. In the tables, the following symbols and abbreviations are used: ΔH_f, the heat of formation in kcal/mol; E_{HOMO} and E_{LUMO}, the highest occupied and lowest unoccupied molecular orbital energies, respectively,

DISCUSSION

Figure 4 illustrates the final geometries of all of the PM3-calculated Möbius coronenes and kekulenes. The results, based especially upon vibrational analyses and heats of formation calculations, suggest that each of the Möbius isomers of coronene, [12]kekulene, and [18]kekulene are real minima on their respective potential energy surfaces. The lowest energy Möbius isomer of coronene, $(ABA)^6C^6$-Möbius coronene, is about 150 kcal/mol less stable than coronene itself, while similar computations of the lowest energy Möbius isomers of [12]kekulene and [18]kekulene yield values of about 53 kcal/mol and 29 kcal/mol, less stable, respectively, indicating that the larger rings can accommodate the strain of the Möbius half twist. These isomers may be better targets for synthetic studies.

An additional isomer of $(ABA)^6C^6$-Möbius-coronene has arisen in the PM3 calculations, and is also illustrated in figure 4. This isomer has apparently relieved some of the twisting strain by forming four-membered rings reminiscent of "Dewar benzene".

The previously reported descriptor system adequately describes the different possible Möbius isomers of these coroniods. However, the values obtained for the [12]kekulene isomers $(BAABC)^6(DDE)^6$ and $(BAABC)^6(EDD)^6$ are computationally identical. Adjacent cuts and twists appear to produce identical isomers. The [18]kekulene isomers $(BAABCDC)^6(EEFGF)^6$, $(CBAABCD)^6(EEFGF)^6$ and $(CBAABCD)^6(FEEFG)^6$ are also computationally identical.

Synthesis of (-)-(S)-4b, (S)-8b, (S)-8c, (S)-8d Diisopropyl 4b,8b,8c,8d-tetrahydrodibenzo[a,f]cyclopropa[c,d]pentalene-8b,8c-dicarboxylate: A Project on Absolute Asymmetric Induction

Kimberly Johnson and Jacob E. Simpson, Jr

Department of Chemistry, Furman Unviersity, Greenville, SC 29613

Faculty Advisor: Moses Lee

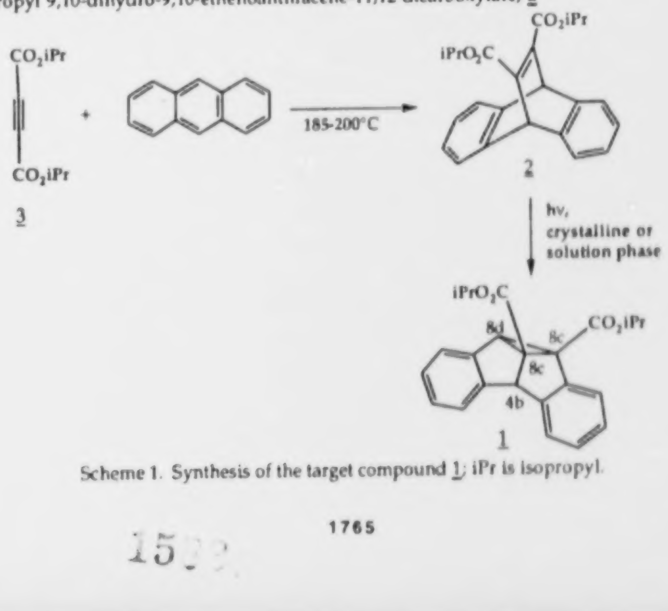
A laboratory project on the absolute asymmetric induction of the titled compound 1 from a solid phase photochemical rearrangement of the achiral compound 2 is described. Compound 1 generated in this way was found to be optically active and had an enantiomeric excess of 20% favoring the (-)-(S)-4b, (S)-8b, (S)-8c, (S)-8d enantiomer. In comparison, a similar solution phase photochemical reaction gave product 1 as a racemic mixture.

BACKGROUND

One of the areas in organic chemistry that is receiving a lot of attention is asymmetric synthesis, i.e. preparation of optically active compounds from achiral substrates (Crosby, 1991). Examples of methods of asymmetric induction involve the use of chiral auxiliaries and chiral catalysts, including the use of enzymes and catalytic antibodies (Trost, 1994). It is our plan to develop laboratory exercises that demonstrate these concepts of asymmetric induction in our organic chemistry curriculum. While a series of laboratory projects that demonstrate the use of chiral auxiliaries (Lee, et al., 1995) and enzymes (Lee, et al., 1994) to achieve asymmetric induction have been published, there has been no reports of a laboratory project that illustrates the concept of absolute asymmetric induction.

Absolute asymmetric induction is a process to prepare optically active compounds directly from achiral reactants without external intervention of pre-existing optically active groups, and it is unique to the crystalline phase. A number of examples of absolute asymmetric syntheses have been reported (Penzien and Schmidt, 1969; Evans, et al., 1986; Garcia-Gaibay, et al., 1986; Chen, et al., 1992; Caswell, et al., 1993; Scheffer, 1994). In these reactions, either enantiomer could be preferentially formed depending on which crystalline enantiomorph was formed predominantly. Therefore the probability of producing mainly one enantiomer is high in one reaction, but over an infinite number of experiments, exactly equal amount of both enantiomers will be produced. The enantiomeric preference can also be influenced by impurities present in either the sample or by "self seeding" of an enantiomer. As part of a plan to design a project to demonstrate the phenomenon of absolute asymmetric induction, the synthesis of the titled compound was developed. This project also demonstrates the use of various laboratory techniques (extraction, thin layer and column chromatography, vacuum distillation, photochemistry) and spectroscopic (^{1}H-NMR, IR, polarimetry, and circular dichroism) methods that are commonly used in contemporary organic chemistry.

Scheme 1 depicts the synthesis of (-)-4(S)-diisopropyl 4b,8b,8c,8d-tetrahydrodibenzo[a,f]cyclopropa[c,d]pentalene-8b,8c-dicarboxylate, 1, from the achiral diisopropyl 9,10-dihydro-9,10-ethenoanthracene-11,12-dicarboxylate, 2



Scheme 1. Synthesis of the target compound 1; iPr is isopropyl.

(Evans, et al., 1986; Garcia-Gaibay, et al., 1986; Chen, et al., 1992; Caswell, et al., 1993; Scheffer, 1994). Compound 2 has been previously demonstrated to either crystallize from cyclohexane or solidify from its molten form to give visually indistinquishable crystals in two dimorphic space groups, Pbca and $P2_12_12_1$. These crystals have identical metling points but different solid state infrared spectra. X-ray analyses have shown that both dimorphs crystallize in asymmetric conformations, but only the $P2_12_12_1$ crystals are chiral; the Pbca crystals are racemic . Studies published by Scheffer's group have shown that laser-induced photochemical rearrangement of a single $P2_12_12_1$ crystal of compound 2 produced an optically active (-)-compound 1 which has the (S)-4b, (S)-8b, (S)-8c, (S)-8d absolute configuration as the predominant enantiomer .

In this project, photochemical rearrangement reactions were run both in the crystalline and solution phases, and the products were analyzed for optical activity, enantiomeric excess, and the absolute configuration of the predominant enantiomer. The starting material, compound 2 was produced directly from a Diels-Alder reaction of diisopropyl acetylenedicarboxylate 3, which can be readily prepared from esterification of acetylenedicarboxylic acid and isopropyl alcohol.

RESULTS AND DISCUSSION

The crystalline phase photochemical rearrangement of compound 2 was conducted in three separate shortened (3 cm) 5mm quartz NMR tubes. The crystals of 2 that were used in this experiment were obtained from solidifying molten samples in the NMR tubes. The samples were kept under an atmosphere of nitrogen, capped and irradiated at 350 nm and room temperature using medium powered lamps in a Hanovia photoreactor for nine days. The crude product was purified by recrystallization from ethyl acetate and hexanes to remove the unreacted compound 2. Analysis of the concentrated mother liquor by ^{1}H-NMR spectrometry revealed a mixture of the desired adduct 1 (55.8%, i.e. an overall yield of 13%) and some unreacted 2 (44.2%) (see Figure 1).

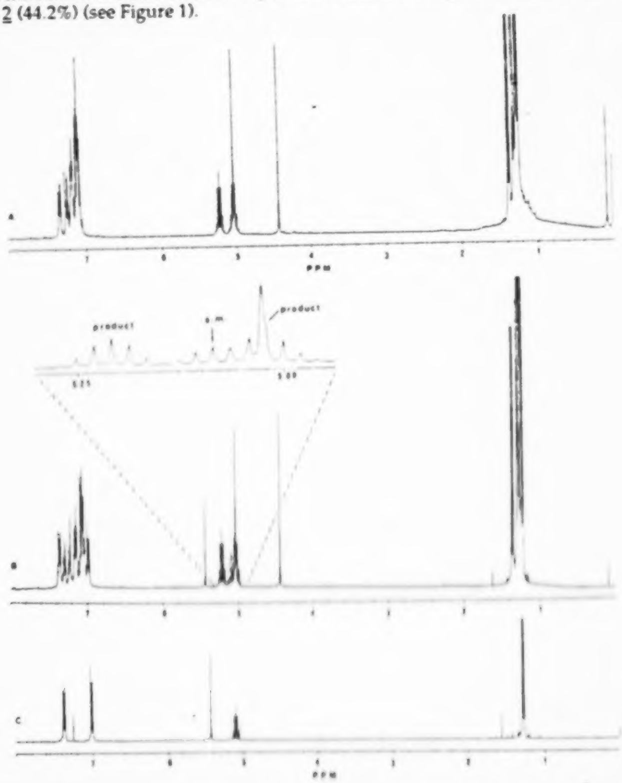


Figure 1. 300 MHz ^{1}H-NMR spectra of compounds 1 and 2. A, compound 1. B, mixture of compounds 1 and 2 that was obtained from the crystalline phase photochemical reaction. An insert of an expansion from 4.90 to 5.30 ppm is given; s.m. denotes starting material. C, compound 2.

This mixture was not purified by silica gel column chromatography because the two compounds co-eluted in all the solvents tested. A chloroform solution of this mixture was found to be optically active, $[\alpha]_{578}$ at 22°C of -7.4° [c = 0.0065g of $\underline{1}$/mL], and since the contaminating compound $\underline{2}$ is optically inactive, it was excluded in the calculation of the value of "c" in the polarimetric analysis. The *minus* optical rotation indicated that the major enantiomer had the (S)-4b, (S)-8b, (S)-8c , (S)-8d absolute configuration (5-9). Additionally, the same chloroform solution of the mixture of $\underline{1}$ and $\underline{2}$ also produced an intrinsic CD band at 246 nm, $[\theta]$ at 22°C = -1.26×10^5 mdeg M^{-1} cm^{-1} (see Figure 2).

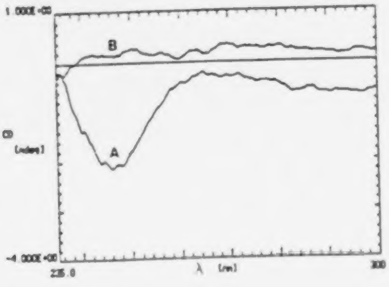

Figure 2. CD spectra of photoproducts. Part A is the spectrum of the mixture of compounds $\underline{1}$ and $\underline{2}$ that was obtained from the crystalline phase photochemical reaction. Part B is for compound $\underline{1}$ obtained from the solution reaction.

As indicated in Figure 3, further analysis of the product mixture by ^{1}H-NMR in the presence of 0.25 molar equivalents of a chiral lanthanide shift reagent [Eu(hfc)3, tris(3-heptafluoropropylhydroxymethylene)-(+)-camphorato] europium (III) showed that the enantiomeric excess (e.e.) of the (-)-(S)-4b, (S)-8b, (S)-8c , (S)-8d enantiomer of compound $\underline{1}$ was 20 ± 4%, i.e. it was present in 60% and the antipode was present in 40%.

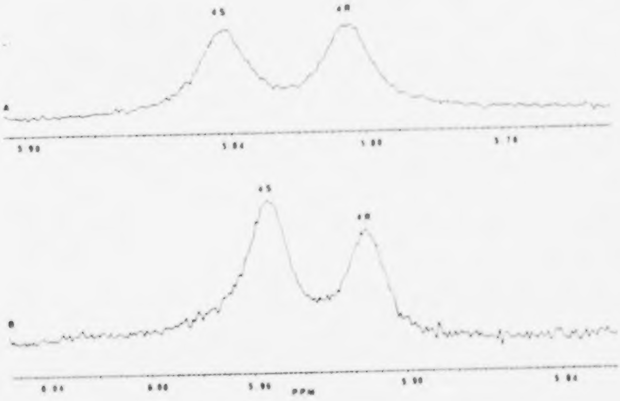

Figure 3. 300 MHz ^{1}H-NMR analyses of the racemic and optically active photoproducts in the presence of 0.25 molar equivalents of Eu(hfc)$_3$. The 4b-(S) [lower field] and 4b-(R) [higher field] signals are indicated. Parts A and B are for compound $\underline{1}$ obtained from the solution and solid reactions, respectively.

As a control experiment, two nitrogen purged solutions of compound $\underline{2}$ in acetone were irradiated at 350 nm for nine days to produce compound $\underline{1}$. Since the starting material $\underline{2}$ was absent in the crude product, it was purified by silica gel column chormatography to give product 1 (see Figure 1) in a combined yield of 38%. Since these reactions were done in a solution phase, it was not surprising that a chloroform solution of the product showed no optical activity at 578 nm [c = 0.0074g/mL], and no intrinsic CD band was seen in the CD spectrum (see Figure 2). ^{1}H-NMR analysis of this product in the presence of 0.25 molar equivalents of $Eu(hfc)_3$ revealed an enantiomeric excess of 0 ± 4%, i.e. a racemic mixture (see Figure 3).

CONCLUSION

This project demonstrates an example of absolute asymmetric induction in the solid phase photochemical rearrangement of the achiral reactant 2 to give an optically active sample of compound 1. The results will contribute to a more complete coverage in the pedagogy of asymmetric induction in organic reactions. Participation in the project will provide students with experience in contemporary laboratory techniques and spectroscopic methods of organic chemistry.

EXPERIMENTAL

Synthesis of disopropyl acetylene aicarboxylate 3

A solution of 5.0 g (0.044 mol) of acetylenedicarboxylic acid in 250 mL of isopropanol and 20 mL of concentrated sulfuric acid was heated to reflux for 2 hrs and 45 min. Upon cooling the reaction mixture to roon temperature 50 mL of water was added, and the solution was then extracted three times (150 mL each) with chloroform. The chloroform extracts were combined, washed with 50 mL of saturated sodium bicarbonate, and dried with anhydrous sodium sulfate. Concentration of the filtrate gave an oil which was distilled using a Kugelrohr apparatus at 75°-80°C and 2.5 mm Hg to yield the desired product 3 as a clear oil (4.25 g, 0.021 mol, 49%). TLC (2.5% $CH_3OH/CHCl_3$) Rf = 0.59. ^{1}H-NMR (300 MHz, $CDCl_3$): δ 1.30 (d, 6.6, 12H), 5.15 (hept, 6.0, 2H). IR (neat): ν 2971, 2356, 1720, 1466, 1374, 1261, 1180, 1099, 1018, 894, 819, 743, 688 cm^{-1}.

Synthesis of diisopropyl 9,10-dihydro-9,10-ethenoanthracene-11,12-dicarboxylate 2

A mixture of 5.0 g (0.28 mol) of anthracene and 6.12 g (0.031 mol) of alkyne 3 was heated at 185-200°C in an oil bath for 1 hour. Upon cooling the reaction mixture to room temperature the contents were dissolved in 75 mL of ethyl acetate, and then 125 mL of hexanes was added to precipitate the remaining anthracene. Concentration of the filtrate gave an solid residue which was purified by silica gel column chromatography using a solvent of 5% ethyl acetate: 95% hexanes to give the desired compound as a white solid. The solid was recrystallized from cyclohexane, and the crystals were collected and dried in a vacuum oven at 40°C, about 1 mm Hg, to yield product 2 (5.67 g, 0.015, mol, 44%). TLC (10% ethyl acetate/hexanes) Rf = 0.36. Mp 145°C [Lit. 145 -146 °C (5-9)]. IR (KBr-pellet): ν 2966, 1713, 1631, 1455, 1267, 1220, 1149, 1096, 1044, 908, 838, 750, 673, 609 cm^{-1}. ^{1}H-NMR ($CDCl_3$): δ 1.28 (d, 6.9, 12H), 5.09 (hept, 6.3, 2H), 5.42 (s, 2H), 6.98 - 7.38 (m, 8H).

Solution Phase Phtochemical Rearrangement of Compound 2 Synthesis of Diisopropyl 4b,8b,8c,8d-tretahydrodibenzo[a,f]cyclopropa[c,d]pentalene-8b,8c-dicarboxylate 1

Two separate samples of 45.3 mg (0.120 mmol) and 45.9 mg (0.122 mmol) of compound 2 were placed into two separate 10 mm quartz NMR tubes were dissolved in 10 mL of acetone. After the solutions were degassed with a gentle stream of nitrogen they were sealed and the caps were wrapped with parafilm. The reaction tubes were placed in a photoreactor at 350 nm at room temperature for 9 days. The samples were combined, concentrated, and purified by silica gel column chromatography using an initial solvent of 2% ethyl acetate: 98% hexanes. The percantage of ethyl acetate of the solvent was raised consecutively to 4, 6, 8 and finally 10% after every 50 mL of solvent. The desired fractions were combined and concentrated to an oily product 1 (35.2 mg, 0.094 mmol, 38%). TLC (10% EtOAc/ hexane) Rf = 0.43. IR (neat): ν 2966, 1719, 1461, 1378 1284, 1243, 1102, 1031, 1044, 908, 826, 732, 614 cm^{-1}. ^{1}H-NMR ($CDCl_3$): δ 1.21 (d, 6.5, CH_3), 1.25 (d, 6.5, CH_3), 1.27 (d, 6.6, CH_3), 1.35 (d, 6.6, CH_3), 4.43 (s, 8d-H), 5.02 (s, 4b-H), 5.03 (hept, 6.5, CH-isopropyl), 5.22 (hept, 6.8, CH-isopropyl), 7.04 - 7.31 (m, 8H). $[\alpha]_{578}$ 22°C = 0 (c = 0.0074 g/mL). No CD band present. ^{1}H-NMR studies with 0.25 molar equivalent $Eu(hfc)_3$: 5.842 ppm for the (S)-4b, (S)-8b, (S)-8c, (S)-8d enantiomer (50.2%), and 5.805 ppm for corresponding R,R,R,R-enantiomer (49.8%), hence e.e = 0.4 ± 4%.

Crystalline Phase Phtotochemical Rearrangement of Compound 2

Three separate samples of adduct 2 (2 x 200 mg, 0.532 mmol; 210 mg, 0.558 mmol) were introduced into three shortened (3 cm) 5-mm quartz NMR tubes. The tubes were selaed under nitrogen, and wrapped with parafilm. The samples were heated in a hot mineral oil bath at 145-160°C for 20 minutes, until the samples had melted. After the smples had solidified at room temperature over a 5 day period they were placed in the photoreactor at 350 nm and room temperature for 9 days. The contents of each of the tubes were dissolved in 15 mL of

A catalyst system consisting of a tungsten oxyphenolate complex [$WOCl_3(OC_6H_3$-2,6-$Cl_2)$] and tributyltin hydride (Bu_3SnH) was used in the olefin metathesis polymerization of dicyclopentadiene. An industrial process for this polymerization was modified using a 50% dilution of the reactants with methylcyclohexane and quenching the reaction with methanol at the gel stage to produce some soluble polydicyclopentadiene for HNMR. Computational methods were used to predict the monomeric subunit formed in the polymerization.

INTRODUCTION

The polymerization of dicyclopentadiene, is an olefin metathesis reaction. Olefin metathesis (1) is a general reaction of unfunctionalized and, in select cases, functionalized alkenes.[1]

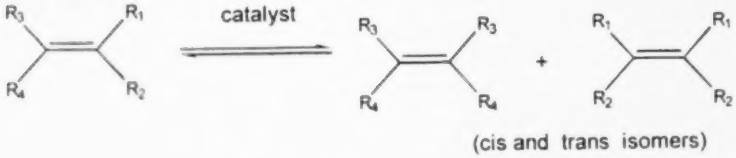

Figure 1: Olefin Metathesis

The most common metathesis catalysts involve a transition metal halide and main group alkylmetal co-catalyst. The generally accepted reaction mechanism involves the reversible addition of a transition metal alkylidene to an alkene to form a metalocyclobutane.[1]

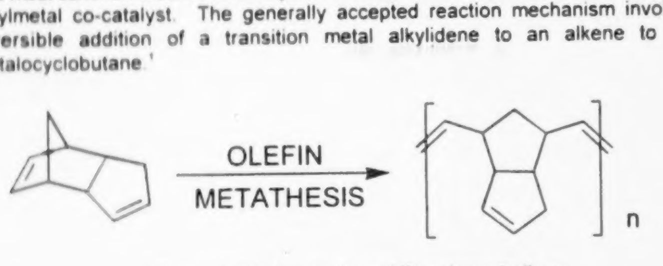

Figure 2: Polymerization of Dicyclopentadiene

The metathesis of dicyclopentadiene catalyzed by a tungsten oxyphenolate complex/tributyltin hydride catalyst system (2) is an equilibrium controlled process.[2] The product, polydicyclopentadiene, is a polymer in which the double bond of the bicyclo[2.2.1] ring system is metathesized.[1]

The purpose of this research was to propose a suitable method to form soluble polydicyclopentadiene in an undergraduate organic laboratory setting. An industrial procedure[2] was used as the basis for the polymerization. This procedure was then modified to produce soluble polydicyclopentadiene and to use conventional organic laboratory equipment in the process.

EXPERIMENTAL

general methods

All reactions were performed under inert atmosphere. Flushing with an inert gas (N_2 or Ar) was performed by bubbling N_2 or Ar through a septum and DCPD with a needle. An air exit needle was put in the septum to allow air to escape as the test tube filled with inert gas. This bubbling was allowed to take place until one was sure the tube was full of inert gas (1-2 minutes). All additions of reagents were performed by syringe.

tungsten catalyst ($WOCl_3(HOC_6H_3\text{-}2,6\text{-}Cl_2)$) preparation

Modifications of a published procedure[3] were employed. $WOCL_4$ (1.14 g) was stirred (not dissolved) in methylcyclohexane (15 mL). 2,6-dichlorophenol ($HOC_6H_3\text{-}2,6\text{-}Cl_2$) (0.54 g) was added to methylcyclohexane (7.5 mL) and stirred until the 2,6-dichlorophenol was dissolved. The phenolic solution was added dropwise over 30 minutes to the methylcycloexane/$WOCl_4$ solution. The reaction mixture was stirred at room temperature with a magnetic stir bar for two hours. The catalyst was used as a solution (0.1 mL).

polydicyclopentadiene preparation

Modifications of a published procedure[4] were employed. Solution 1 of dicyclopentadiene (DCPD) (2.00 mL), Bu_3SnH (0.0156 mL), $P(OBu)_3$ (0.0240 mL), and methylcyclohexane (2.00 mL) was made in a test tube flushed with N_2. Solution 2 of dicyclopentadiene (2.00 mL), $WOCl_3(OC_6H_3\text{-}2,6\text{-}Cl_2)$ (0.00688 g), 2-methoxyethyl ether (diglyme) (0.0044 mL), and methylcyclohexane (2.00 mL) was made in a flask flushed with N_2. Solution 2 was added to Solution 1 via syringe. The product solution was mixed and placed in a hot tap water bath. When the polymer entered the gel stage, it was dumped into methanol (~30 mL) and stirred to collect the polymer in one piece.

polydicyclopentadiene workup

The polymer was filtered through a Buchner funnel. The precipitate was dried under a vacuum pump. The precipitate was dissolved in chloroform (~30 mL). The solution was filtered, and the clear solution was rotary evaporated. The film on the flask (dissolved polydicyclopentadiene) was scraped with a spatula and placed in an NMR tube with deuterated chloroform. The HNMR (200 MHz) was performed.

computational methods

Macrmodel 3.5 was used on an "Indy" silicon graphics workstation to predict the subunit of polydiciyclopentadiene formed in the metathesis: endo-5 or endo-6, by comparing the relative energies of the subunits.

RESULTS AND DISCUSSION

The computational results from MacroModel gave a 216.49 kJ/mol energy for the reaction pathway to endo-5 and a 157.43 kJ/mol energy for the pathway resulting in endo-6. Due to thermodynamic control for the polymerization, the endo-6 product is formed due to the lower energy of the conformer. The literature NMR of polydicyclopentadiene used to compare with experimental NMRs was for the endo-6 conformer. The experimental NMRs compared favorably to the endo-6 literature NMR.

The experimental modification from the literature method used in industry proved to be somewhat successful. Enough soluble polydicyclopentadiene was produced to run an NMR, but not a large amount. There are many complications with these modifications. One of these is the determination of the gel stage. There is a very small window in which soluble polydicyclopentadiene can be obtained. If one quenches the reaction prematurely no product is formed, but if one waits too long no soluble polydicyclopentadiene is formed. The oxyphenolate catalyst system is very unstable, its reactivity changes (i.e. different amounts of catalyst are needed on different days) and it lasts for a maximum of two weeks. The amount of dissolved polymer is very small (around 0.1g). The experimental NMRs of this dissolved polymer have some impurities

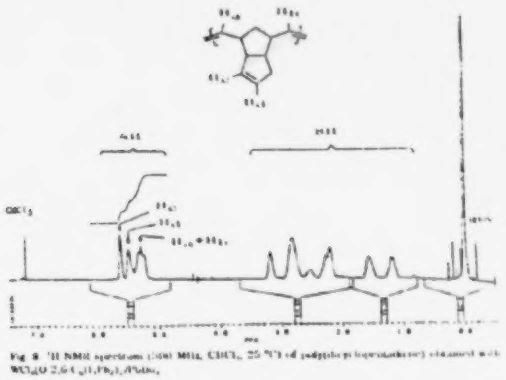

Figure 3: Literature HNMR Spectrum of PDCPD

in them (i.e. monomer) compared to the literature spectrum above.[2]

More work is currently being done at Miami University on this research project. different catalyst systems are being used to attempt to form a linear soluble polymer rather than a mostly insoluble, cross-linked polymer as was formed using the oxyphenolate catalyst system.

In the experimental spectrum below, there are peaks at 5.9 ppm and 3.9 ppm thatare not in the literature spectrum of polydicyclopentadiene. The peak at 5.9 ppm is due to dicyclopentadiene (monomer) that could not be gotten out of the polymer. The peak at 3.9 ppm is unknown as to what it may be due.

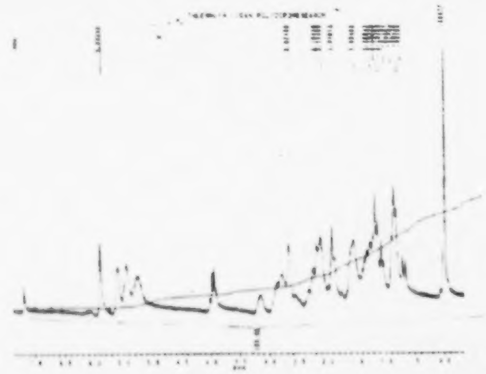

Figure 4: Experimental HNMR Spectrum of Dicyclopentadiene

CONCLUSION

Soluble polydicyclopentadiene can be formed using an oxyphenolate complex to catalyze the polymerization of dicyclopentadiene and following the experimental method described previously. The amount of soluble polymer produced by this method is not large, but an HNMR can be performed on the dissolved polydicyclopentadiene. These experimental HNMRs compare favorably to the literature HNMR for polydicyclopentadiene. Computational methods can be used to predict the subunit formed in the polymerization, endo-6.

ACKNOWLEDGEMENTS

The author wishes to express his appreciation to those at Miami University, namely Dr. James W. Hershberger, Karl Thuemmler, and graduate students Ken Chan and Ben Williams. The author also thanks Mrs. Elsie Smith, Mrs. Carol Leslie, and Dr. Randy Johnston at Union University for writing letters of recommendation. I would like to thank the Miami University Department of Chemistry for providing the facilities for the research. Lastly, I would like to thank the National Science Foundation and The Howard Hughes Medical Research Fellowship for providing funding for the research.

EXAMINATION OF THE DECARBOXYLATION OF KETOISOVALERATE USING PYRUVATE DECARBOXYLASE FROM *Saccharomyces cerevisiae*

Michael B. Meek

Betty H. Stewart

Pyruvate decarboxylase from *Saccharomyces cerevisiae* (SCPDC) is a hysteretically regulated enzyme that catalyzes the decarboxylation of α-keto acids to the corresponding aldehyde and CO_2. The kinetics of the decarboxylation of ketoisovalerate (KIV), an analog of pyruvate, the normal substrate of SCPDC, were examined. The sigmoidal characteristics of substrate activation were observed for both pyruvate and KIV. However, the mechanisms of regulation and catalysis for these substrates are different.

INTRODUCTION

Pyruvate decarboxylase catalyzes the decarboxylation of pyruvate to acetaldehyde and carbon dioxide in the anaerobic alcoholic fermentation pathway following glycolysis. This enzyme not only catalyzes the decarboxylation of pyruvate, but also a number of α-keto acids including aromatic β-substituted α-keto acids. (Sun, 1995) This enzyme also requires a coenzyme, thiamin diphosphate and a cofactor, magnesium sulfate, and is usually purified as a holo-enzyme with thiamin diphosphate (ThDP) and magnesium tightly bound at neutral pH. (Ullrich, 1970)

Pyruvate decarboxylase from *Saccharomyces cerevisiae* (SCPDC) is a tetramer with a molecular weight of 242 kDa, with one ThDP and magnesium binding site per monomer. (Lindqvist and Schneider, 1993) SCPDC is hysteretically regulated by its substrate, and a plot of reaction rate as a function of substrate concentration gives a sigmoidal curve at low substrate concentrations, which indicates substrate activation (Boiteux and Hess, 1970) Recently, a mechanistic model for regulation and catalysis was developed by Alvarez et al. based on isotope effects and proton inventories. Alvarez et al. suggested that sulfhydryl addition to the regulatory molecule occurs within each catalytic cycle, acting as a switch to open the active site to permit substrate in or allow the product out. (Alvarez, 1995)

Because SPDC decarboxylates a number of α-keto acids, the mechanism of action is fully understood. The model suggested by Alvarez et. al. is based on pyruvate as the α -keto acid. This study examined the catalysis of ketoisovalerate (KIV), an analog of pyruvate containing an isopropyl group, to test the Alvarez et. al. model. Steady-state kinetic experiments and proton inventory experiments were performed to study the detailed mechanism of action of SCPDC. The proton inventory experiment contributed to the understanding of regulation and catalysis of SCPDC by pyruvate and the larger substrate, KIV.

EXPERIMENTAL

Several enzymes and cofactors including the SCPDC, cocarboxylase (ThDP), nicotinamide adenine dinucleotide (NADH, reduced form) and ketoisovalerate were purchased from Sigma Chemical Co. The liver alcohol dehydrogenase (LADH) was purchased from Fluka and the sodium citrate, citric acid and magnesium sulfate were purchased from Fisher Scientific. A 0.10 M sodium citrate buffer was used in both the water form (pH=6.2) and deuterated form (pH=6.3). A 0.10 M solution of the magnesium sulfate and thiamin diphosphate were also prepared for use in the SCPDC solution. A typical SCPDC solution contained 9.2 nM SCPDC, 0.3 U/mL LADH, 5 mM magnesium and ThDP, 0.265 mM NADH and varying concentrations of KIV (0 - 50 mM). For the full saturation kinetic runs, a typical assay vessel would consist of a set volume of SCPDC solution followed by a varying amount of citrate buffer and substrate to a total volume of 1 mL. (Sun, 1995) The assay was measured at 360 nm and was allowed to run for 200 seconds with the absorbance being recorded every two seconds. The kinetics of the decarboxylation reaction were measured indirectly by a secondary coupled reaction that used liver alcohol dehydrogenase (LADH). In this reaction, NADH is oxidized to NAD^+ as LADH reduces the acetaldehyde to ethanol. NAD^+ does not absorb at 360 nm, as does NADH, thus, a negative absorbance is recorded.

A proton inventory is a solvent isotope experiment that leads to a definition of the number of exchangeable protons in the structure of an enzyme's catalytically active site. The reaction kinetics, or rate velocities, are determined in a series of isotopic water solvents. It begins with pure protium oxide and works up through mixtures of increasing atom fraction of deuterium to nearly pure deuterium oxide. The result is a compilation of rates as a function of the atom fraction of deuterium present in the solvent. This yields a list of kinetic isotope effects at each of the contributing sites, thus a proton inventory. The velocity was determined using the different atom fractions of deuterium based on a rate calculated from the full saturation kinetics. The interpretation lends itself to the shape of the curve. (Venkatasubban and Schowen, 1984)

RESULTS AND DISCUSSION

We examined the mechanisms of regulation and catalysis by SCPDC with KIV. Steady state saturation kinetic assays of SCPDC with KIV are shown in Figure 1.

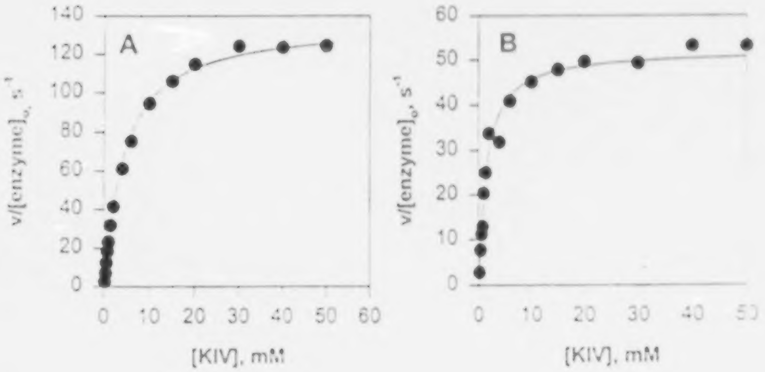

Figure 1. Steady-state saturation curves for the decarboxylation of KIV with catalysis by SCPDC at different atom fraction of deuterium, n.
(A) n = 0.0, (B) n = 0.99

A specific rate constant, k, was calculated for each assay using a modified version of the Michaelis-Menten equation. (Alvarez, 1995) The rate constant, k, is zero order with respect to substrate. It describes the events from reactant state to transition state for both decarboxylation and product release. (Sun, 1995)

Figure 2 shows the proton inventory of SCPDC with pyruvate and KIV.

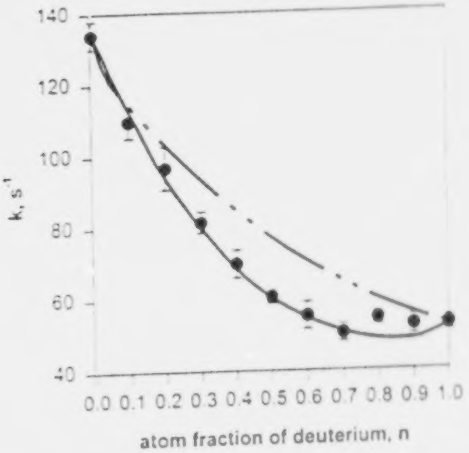

Figure 2. Proton inventory of SCPDC with Pyruvate and KIV Dashed line represents pyruvate data and solid line re[resemts KIV data

Pyruvate forms a "hypercurve" that suggests multiple protons being exchanged in the active site. In the mechanistic model of hysteretic regulation and catalysis by SCPDC with pyruvate proposed by Alvarez et al., the substrate enters the regulatory domain of the enzyme and binds to the sulfhydryl group of a cysteine residue. Sulfhydryl addition activates the enzyme through a conformational change, which opens the enzyme's active site. Sulfhydryl elimination in the regulatory domain closes the active site and the catalytic cycle begins. Entry of the pyruvate into the active site is the rate-determining step. SCPDC decarboxylates pyruvate, releasing CO_2 and aceta'dehyde Sulfhydryl addition in the regulatory domain opens the active site and acetaldehyde is released. Decarboxylation and product release are equally rate-limiting. Sulfhydryl elimination then closes the active site and prepares for another catalytic cycle

KIV forms a "super hypercurve" that suggests multiple protons are being exchanged in the active site also. Figure 3 presents a model for regulation and catalysis by SCPDC with KIV

Figure 3. Possible model for regulation and catalysis by SCPDC with KIV

For KIV, the rate determining step is removal of the proton from ThDP by a base, accompanied by a conformational change in SCPDC. This rate determining step using KIV is relatively fast and unobserved using pyruvate as substrate. Both generation of acetaldehyde and product release are rate-determining.

Although the shapes of the proton inventory curves for pyruvate and KIV are similar, the mechanisms of regulation and catalysis are different. KIV, which has a bulky isopropyl R-group, slows the rate of catalysis due to increased steric strain placed on the enzyme in both the regulatory and active sites. In addition, increased electronic effects of KIV are involved with the isotope effects.

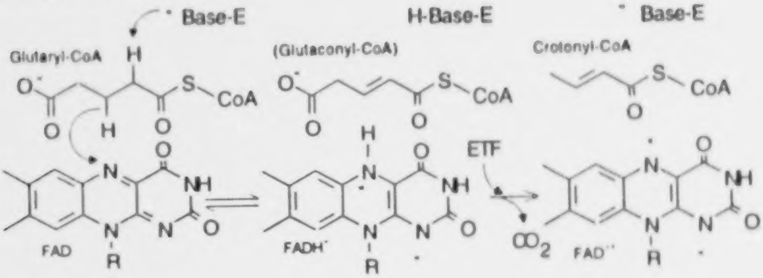
INTRODUCTION

The acyl-coenzyme A (CoA) dehydrogenases are a class of enzymes responsible for the oxidative breakdown of fatty acids and amino acids as well as the transfer of electrons to electron transfer flavoprotein (ETF). ETF works to shuttle electrons between the acyl-CoA dehydrogenases and the electron transport chain for the production of ATP for the cell.

Glutaryl-CoA dehydrogenase (GCD), an acyl-CoA dehydrogenase, plays a role in the breakdown of the amino acids lysine, hydroxylysine, and tryptophan. It also catalyzes the oxidation and subsequent decarboxylation of the substrate, glutaryl-CoA, to crotonyl-CoA according to Equation 1 (Gomes, et. al., 1991).

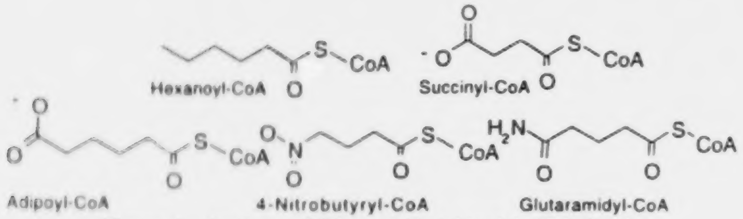


Equation 1: Mechanism of GCD

Individuals born with specific mutations in this enzyme develop certain metabolic illnesses, such as Glutaric Aciduria Type I, that lead to death within the first decade of life. The mutations in the enzyme are thought to interfere with the electron transfer that occurs between the enzyme and its substrate. Therefore, it is important to study the electrochemical relationship between GCD and its substrate, glutaryl-CoA, so that better ways to understand these metabolic illnesses may be elucidated.

Because the reaction occurring between GCD and its substrate results in the elimination of CO_2, it is an irreversible reaction. This irreversibility complicates electrochemical study of the enzyme:substrate complex and thus it becomes necessary to look at analogs of the substrate. The purpose of this study was to evaluate commercially available and synthetic analogs of glutaryl-CoA to determine the extent of their activity (if any) with GCD.

The analogs chosen for this study include hexanoyl-CoA, succinyl-CoA, adipoyl-CoA, 4-nitrobutyryl-CoA, and glutaramidyl-CoA. Their structures are shown below. It can be seen, for example, that hexanoyl-CoA is similar in chain length to glutaryl-CoA but lacks a carboxyl group. Succinyl-CoA has



Hexanoyl-CoA

Adipoyl-CoA
4-Nitrobutyryl-CoA
Glutaramidyl-CoA

Figure 1. Analogs of Glutaryl-CoA Used in This Study

one less methylene group than glutaryl-CoA while adipoyl-CoA has one more methylene group. These features should prevent decarboxylation. 4-Nitrobutyryl-CoA contains a nitro, rather than a carboxylic acid group. The nitro group of this analog is isoelectronic with the carboxylic acid group of glutaryl-CoA and thus should mimic the binding properties of the carboxyl group of glutaryl-CoA. Finally, glutaramidyl-CoA contains an amide in place of the carboxylic acid group found on glutaryl-CoA. This amide is also believed to mimic the carboxylic acid group present in glutaryl-CoA. For these reasons, it is feasible that these analogs may show activity with GCD.

Hexanoyl-CoA and succinyl-CoA are commercially available. The syntheses of adipoyl-CoA and 4-nitrobutyryl-CoA are based on the following general reaction scheme (Bernert and Sprecher, 1977). First, the acid derivative is reacted with ethyl chloroformate to produce the anhydride. This product is next reacted with a lithium CoA (LiCoA) salt, yielding the acyl-CoA derivative.

Li-S-CoA
2:1 Water/THF
pH 8
Acyl-CoA

Equation 2: Synthesis of Adipoyl-CoA and 4-Nitrobutyryl-CoA

Since glutaramidyl-CoA has not been previously synthesized, a model reaction between glutarimide and a small sulfhydryl compound was developed as a basis for the CoA reaction. This model reaction is shown below. In this reaction, glutarimide is subject to a nucleophilic attack by mercaptoethanol. This attack breaks open the ring to yield the resulting amide and thioester. The success of the reaction would provide grounds for the plausibility of the synthetic scheme for glutaramidyl-CoA formation. Similarly to the model reaction using mercaptoethanol, glutarimide should also be subject to a nucleophilic attack by LiCoA, thereby yielding the desired product.

EXPERIMENTAL

Unless otherwise stated, all reagents used in these studies were purchased commercially (Aldrich, Milwaukee, WI and Sigma, St. Louis, MO) and were used without further purification. Absorbance measurements were obtained using a Hewlett-Packard 8452A uv/vis diode array spectrophotometer. Nuclear magnetic resonance spectra were obtained using a Varian Model EM360L spectrometer. Enzymatic assays were performed using human GCD expressed in and purified from *E. coli* using methods described by Husain and Steenkamp (1985) and by Frank E. Frerman (personal communication).

Preparation of Substrate Analogs

Adipoyl-CoA synthesis followed Equation 2. Adipic anhydride was synthesized according to the method of Hill (1930), and coupled to CoA via the method of Bernert and Sprecher (1977) as modified by Lenn (1989). Nitroprusside tests (Stadtman, 1957) confirmed the coupling and product purification was performed using the method of Corkey (1985) as modified by Lenn (1989). The product was stored in a concentrated aqueous solution at -20 ^{o}C.

4-Nitrobutyryl-CoA was synthesized according to Kultgen, et. al. (1997). Nitroprusside tests confirmed CoA coupling and product purification was performed as above. The product was stored in a concentrated aqueous solution at -20 ^{o}C.

For the reaction described in Equation 3, 0.0136 g of glutarimide were dissolved in 3 mL of 2:1 H_2O/THF solution. This solution was transferred to a 5 mL conical vial and refluxed with 25.3 µL of mercaptoethanol and 19 µL of NaOH (pH 9) for 4 hr. Next, the pH of the solution was adjusted to 3 using 6 M HCl, and the resulting mixture was washed 3 times with ether. The aqueous layers were collected and lyophilized. The resulting precipitate was dissolved in a minimum amount of D_2O for NMR analysis.

The synthesis of glutaramidyl-CoA was carried out in accordance with the reaction described in Equation 4, using a 2:1 molar ratio of LiCoA and glutarimide. Glutarimide (2.5 µg) and 31.6 µg of LiCoA salt were dissolved in 3 mL of a 2:1 solution of H_2O/THF. This solution was transferred to a 5 mL conical vial fitted with a reflux condenser, stir vane, and boiling chips. The pH of the solution was adjusted to 9 using concentrated NaOH. The solution was refluxed for 2 hours. Next, 2 drops of 6 M HCl were added, and the resulting mixture was washed 3 times with ether. The aqueous layers were collected and lyophilized. The resulting precipitate was dissolved in a minimum amount of deionized H_2O for purification according to the method described by Williamson (1983). The dissolved precipitate was applied to a DEAE Sephadex A-25 column (1.5 X 22 cm). A linear gradient of 0.2 M NaCl/0.1 mM HCl (80 mL) to 0.6 M NaCl/0.1 mM HCl (100 mL) was used for elution. The A_{260} and A_{232} of the collected fractions were monitored. A plot was constructed of A_{260} versus fraction number. Two peaks appeared on the graph indicating two sets of fractions with a higher concentration of CoA. The fractions corresponding to each peak were consolidated and lyophilized. The resulting precipitate of each sample was dissolved in a minimum of deionized H_2O. An absorbance spectrum was recorded for each sample from 200 nm to 310 nm. These spectra were compared to spectra of a known coupled CoA analog and a free CoA sample of the same wavelength range to determine which fractions contained excess CoA and which contained coupled CoA. Pooled fractions were stored at -20 ^{o}C.

Assays for Analog Activity with GCD

GCD assays were performed similarly to that described by Husain and Steenkamp (1985). Assay stock solutions were prepared containing 100 mL of 0.1 M KPi buffer (pH = 7.5, RT) and 1.7 mg of 2,6-dichlorophenolindophenol. For glutaryl-CoA, hexanoyl-CoA, and succinyl-CoA assays, separate 1 mL stock solutions containing 0.00111 g of an individual CoA derivative were first prepared. An individual 250 µL aliquot of a CoA derivative stock solution was then added to a 25 mL aliquot of the assay stock solution. Three milliliters of this stock + CoA derivative solution was added to a standard cuvette, followed by 30 µL of a 0.13 M aqueous phenazine methosulfate solution, and 50 µL of GCD. The decrease in absorbance of this mixture with time was monitored at 600 nm to determine GCD activity. For adipoyl-CoA, 4-nitrobutyryl-CoA, and impure glutaramidyl-CoA, assay quantities were determined by measuring the A_{260} of stored aqueous analog and comparing this value to the A_{260} of glutaryl-CoA at the concentration at which glutaryl-CoA is used for GCD assays. Appropriate dilution factors were calculated to ensure that when small (µL) aliquots of each analog solution were added to 2.9 mL of the assay stock solution and 30 µL of the 0.13 M phenazine methosulfate solution, that the final assay mixture was consistent in analog concentration with glutaryl-CoA final assay mixtures. Ten microliters of GCD were added to the final assay mixture and the A_{600} was monitored as before to determine activity. An assay using glutaryl-CoA was repeated at this time using 10 µL of GCD.

RESULTS AND DISCUSSION

Successful modeling of the glutaramidyl-CoA reaction using mercaptoethanol is shown by the NMR spectrum presented in Figure 2.

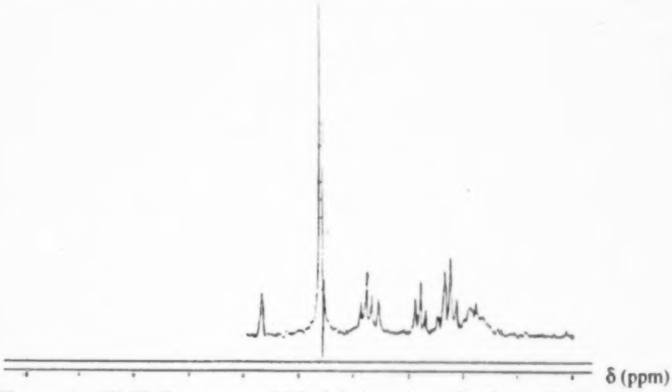

Figure 2. NMR Spectrum of Model Reaction. Scale reads from 0 - 10 ppm.

This spectrum shows peaks characteristic of the thioester product. The broad multiplet at 1.6 ppm corresponds to the two hydrogens of the carbon β to the thioester. The two overlapping triplets at 2.2 ppm coincide with the four hydrogens on the carbons α to the two carbonyl groups. The triplet at 2.7 ppm is indicative of the methylene hydrogens next to the sulfur atom and the triplet at 3.8 ppm corresponds to the methylene hydrogens next to the alcohol group. Spinning side bands of the large H_2O peak are found at 3.5 ppm and 5.7 ppm. This H_2O peak at 4.1 ppm is a result of the exchangeable hydrogens of the amide and alcohol groups. This successful model synthesis supports the assertion that the glutarimide ring could be broken open through nucleophilic attack to yield the formation of a thioester. The synthesis of glutaramidyl-CoA, however, is still in the process of being confirmed. Evaluation of the fractions collected following the A-25 column for their A_{232}:A_{260} absorbance ratios did not yield values near 0.5, the ratio indicative of a clean CoA derivatization (Lenn, et. al., 1990). However, GCD assays performed with impure product mixtures, discussed below, suggest synthesis of the desired product.

The percent activities in Table 1 were calculated by dividing the GCD activity with the analog by the GCD activity with its native substrate, glutaryl-CoA. All five analogs show evidence of activity with GCD and thus appear viable for future GCD electrochemical studies.

Table 1. Table of Analog Activities

Analog	*Percent Activity*
Hexanoyl-CoA	44.4
Succinyl-CoA	13.4
Adipoyl-CoA	3.4
4-Nitrobutyryl-CoA	4.7
Glutaramidyl-CoA (impure)	14.1

As of yet, this study remains incomplete. More work is needed on the characterization and purification of the analog, glutaramidyl-CoA. However, this study was successful in that the synthesis of three substrate analogs and the elucidation of their activity with GCD were able to be evaluated. This data, by shedding some light on the interaction of GCD with its substrate, will be helpful to the ensuing electrochemical studies of GCD:substrate analog complexes as well as be helpful to others wishing to synthesize similar acyl-CoA derivatives.

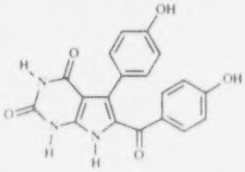
Dr. Keith Krumpe and Dr. John Gupton

A main emphasis of this research group in past years has been to develop new approaches for the synthesis of interesting and important pyrroles. It has been demonstrated that the pyrrole is a central structure in many naturally occurring, bioactive compounds. One such molecule is Rigidin. It has been shown to be important in the regulation of Calmodulin activated phosphodiesterase and a potential chemotheraputic agent. This effort towards the synthesis of Rigidin has focused on a "pyrrole-first" approach. This work details the synthesis of a trisubstituted pyrrole intermediate and outlines the planned approach to the target molecule.

INTRODUCTION

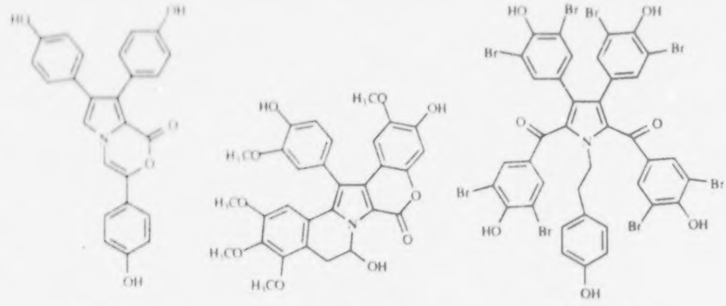
An active area for organic chemistry research continues to be the discovery and synthesis of new chemotherapeutic agents for the treatment of various forms of cancer. One specific target of recent efforts has been Calmodulin.[1] It is a protein that binds up to four calcium ions at a time, and has been shown to be an activator of a particular molecular form of phosphodiesterase. It is also a major contributor to calcium signaling in the cells of all eucaryotic organisms. The regulation of Calmodulin activated phosphodiesterase by a variety of pharmaceutical agents, has been the emphasis of researchers attempting to synthesize antitumor compounds. One such compound, Rigidin (1), has recently been isolated from the Okinawan marine truncate Eudistoma cf. rigida by Kobayashi and coworkers.[2]



1

Figure-1. Rigidin.

Rigidin (1) has at its core, a fundamental cyclic structure called a pyrrole. This moiety is comprised of four carbon atoms and one nitrogen connected in a ring and doubly bound in such a way as to create a conjugated system of pi electrons (an energetically favorable situation). Although the specific mechanism of activity is not completely understood, the pyrrole ring, in addition to its substituents, appears to be important in that it is present in a number of potential chemotherapeutic agents (for examples, see Figure-2).[3]



Lukianol A Lamellarin A Polycitone A

Figure-2. Pyrrole Containing Potential Chemotherapeutic Agents.

Unlike previously reported syntheses[4] that have employed a uracil/pyrimidine first approach, we have elected to utilize a "pyrrole first strategy" to the synthesis of Rigidin (see Figure-3). The key intermediate in this strategy is the trisubstituted pyrrole 3 that results from the condensation of vinylogous amide 4 with aminoketone 5. The western portion of Rigidin (1) can be constructed by introducing an amine in the 5-position of the pyrrole and using it and the ester as a foundation for the uracil ring.[5] With the skeleton complete, the only item remaing in the synthesis is the demethylation of the ethers.

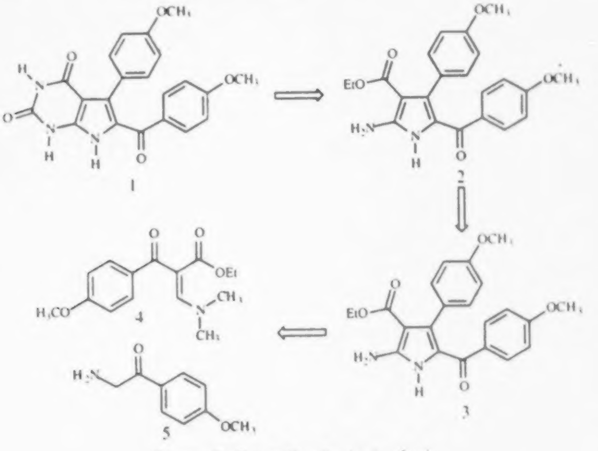


Figure-3. Retro-Synthetic Analysis

This approach to pyrroles can be viewed generally as the coupling of a three-atom unit with a two-atom, nitrogen containing unit (Figure-4). We have found that it allows for the controlled production of a variety of substitution patterns, including: 2,3-disubstituted[6], 2,4-disubstituted[7], 2,5-disubstituted[6,8] and 2,3,4-trisubstituted[9] pyrroles. A number of three carbon synthons are available and can be reacted under different conditions depending upon the nature of the nitrogen-containing unit.

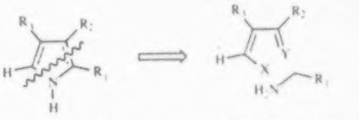

Figure 4. Vinylogous Imine Derivatives — A 3 + 2 Approach to Pyrroles

RESULTS AND DISCUSSION

Trisubstituted pyrrole 3 is the product of a convergent synthesis that utilized two commercially available 4'-methoxyacetophenones (6 and 7) as the initial starting materials (see Figure-5). Claisen condensation[10] of 4'-methoxyacetophenone (6) with diethyl carbonate produced β-ketoester 7 in 85% yield. Without purification, 7 was transformed into vinylogous amide 4 in high yield (78%) by refluxing it with N,N-dimethylformamide dimethyl acetal (DMFA) in dimethylformamide (DMF). This approach to the synthesis of vinylogous amides[11] has been used extensively in our laboratory and provides us with the requisite three-atom units in excellent yields.

The two-atom unit, aminoketone 5, was obtained by first converting 2-bromo-4'-methoxyacetophenone (8) to azide 9 and then reducing it to aminoketone 5a (Figure-5). The azide was obtained in 87% yield by reacting the bromide with an ethanolic solution of sodium azide for 24 hours.[12] Unfortunately the reduction of the azide group to the amine was not as straight forward as was anticipated. Reactions utilizing traditional conditions[13] for the production of amines from azides either resulted in no discernable reaction or produced significant quantities of pyrazine 11 (Figure-6) when reduction did occur . However, it was found that the treatment of the azide with one equivalent of triphenylphosphine[14] and three equivalents of *p*-toluene sulfonic acid (*p*TSA) monohydrate in THF produced analytically pure 5a in 90% isolated yield. The water from the *p*TSA serves to decompose the intermediate phosphorimine (11) while the acid itself traps the aminoketone 5 before dimerization to pyrazine 12 can occur.

Figure-5. Synthesis of Trisubstituted Pyrrole 3.

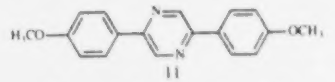

Figure-6. Pyrazine Byproduct

With the two necessary componets in hand, the synthesis of pyrrole 3 was initiated (Figure-5). The first step in the sequence involved the exchange reaction between vinylogous amide 4 and α-aminoacetophenone 5a. This process produced a new vinylogous amide (10) in a crude yield of greater than 95%. Based upon previous studies in our laboratory,[15] it was not surprising that this exchange occurred smoothly. Cyclization of the pyrrole was effected in 30% yield by dissolving vinylogous amide 10 and an additional equivalent of *p*TSA in ethanol and refluxing the solution overnight. It is believed that the protic solvent facilitates enolization of the isolated ketone which undergoes an Aldol condensation with the β-ketoester. The dihyropyrrole (13) that is produced readily eliminates water to produce the energetically favorable aromatic pyrrole 3 (Figure-7).

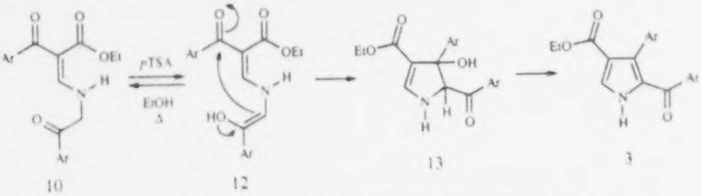

Figure-7. Proposed Mechanism for Pyrrole Formation

CONCLUSION

Although pyrrole 3 has been successfully synthesized, the yield for the cyclization remains less than ideal. Previous work in our group with similar reactions indicates that the reaction is very much substrate dependent. In other words, ideal reaction conditions are very much dependent upon the nature of both the two- and three-atom units that are used. Therefore, we have begun a systematic investigation of this reaction in an effort to maximize its yield. While this study is in progress, trisubstituted pyrrole 3 will be collected so that further progress towards Rigidin can be made. The approach that will be taken is outlined in Figure-8.

Figure-8 Steps Remaining to Complete Rigidin

EXPERIMENTAL PROCEDURES

Synthesis of 2-Carbethoxy-3-dimethylamino-1-(4'-methoxyphenyl)-2-propenone (4)

4.01 g (0.167 mol) of 60% sodium hydride and 47.06 g (0.398 mol, 48.27 ml) diethyl carbonate were suspended in approximately 150 ml of toluene, and this solution was heated to 60° C. 10.0 g (0.067 mol) of 4'-methoxyacetophenone (6) was dissolved in approximately 150 ml of toluene and added dropwise to the above solution over three hours. The reaction stirred and changed from gray to dark orange-brown with an increase in temperature to approximately 70° C within the first 30 min. The reaction was allowed to stir for an additional 48 hrs and monitored by thin layer chromatography. After completion, the solution was cooled to 0° C and 25 ml of glacial acetic acid was added. This mixture was then poured into a mixture of 40 ml of ice and 10 ml of concentrated hydrochloric acid. After being separated, the aqueous layer was extracted with ethyl acetate (3 x 50 ml). The combined organic layers were washed sequentially with saturated sodium bicarbonate solution (2 x 50 ml) and brine (2 x 50 ml), and dried over anhydrous magnesium sulfate. Concentration of solution under reduced pressure afforded 12.6 g (85.1%) of a yellow oil that was identified as ethyl 4'-methoxybenzoylacetate (7) on the basis of the following physical properties: IR (neat) 2918, 2820, 1740, 1675, 1600, 1030, and 840 cm^{-1}; NMR ($CDCl_3$, 200 MHz) δ 1.23 (t, 3H, J=7.1 Hz), 3.84 (s, 3H), 3.92 (s, 2H), 4.18 (q, 2H, J=7.1 Hz), 6.92 (d, 2H J=8.8 Hz), 7.90 (d, 2H, J=8.8 Hz).

2.22 g (10.00 mmol) of the above β-ketoester (7) and 4.77 g (40.00 mmol) dimethyl formamide acetal (DMFA) were added to 100 ml DMF and allowed to reflux and stir overnight. The methanol byproduct was removed on the rotoevaporator under reduced pressure. Concentration by Kughelrohr distillation under reduced pressure afforded 2.18 g (78.5%) of a dark red oil that was idendified as 2-carbethoxy-3-dimethylamino-1-(4'-methoxyphenyl)-2-propenone (4) on the basis of the following spectral properties: IR (neat) 2860-3000, 1675, 1585, 1430, 1375, 1075, 960, 845, 775, 200-600 cm^{-1}; NMR ($CDCl_3$, 200 MHz) δ 0.955 (t, 3H, J=7.0 Hz), 2.77-3.06 (m, 6H), 3.83 (s, 3H), 3.98 (q, 2H, J=7.0 Hz), 6.88 (d, 2H, J=7.4 Hz), 7.66 (s, 1H), 7.80 (d, 2H, J=7.4 Hz).

Synthesis of α-Amino-4'-methoxyacetophenone *p*-toluenesulfonic acid salt (5a).

To a solution containing 3.13 g (40.81 mmol) of sodium azide in 300 ml of ethanol was added a solution of 10.0 g (43.65 mmol) of 2-bromo-4'-methoxyacetophenone (8) in 150 ml of ethanol. After stirring at room temperature for 20 hrs, the solution was concentrated to 1/2 its volume under reduced pressure. The remaining solution was diluted with 250 ml of diethyl ether and washed with 300 ml of water. The organic layer was separated and washed with brine (2 x 50 ml). The original water layer was back extracted twice with ether (2 x 50 ml) and the resulting organic layers were washed again with brine. All organic layers were combined, dried over anhydrous magnesium sulfate, and concentrated. Recrystallization of the resulting yellow crystals from dichloromethane and hexane afforded 7.30 g (87.3%) of pale yellow crystals that were identified as 2-azido-4'-methoxyacetophenone (9) on the basis of the following spectral properties: mp 69.5-71.0°C; IR (neat) 2905, 2105, 2100, 1680, 1590, 1175, and 825 cm^{-1}; NMR ($CDCl_3$, 200 MHz) δ 3.88 (s, 3H), 4.50 (s 2H), 6.96 (d, 2H, J=9.2 Hz), 7.89 (d 2H, J=9.2 Hz).

2.00 g (10.46 mmol) of the above azide (9), 2.74 g (10.46 mmol) of triphenyl phosphine and 5.97 g (31.38 mmol) of *p*TSA were combined in THF (100 ml) and allowed to stir overnight at room temperature. The resulting white crystalline solid was filtered and dried under reduced pressure. The yield of solid product was 1.80 g (90.0%) and it was identified as 2-amino-4'-methoxyacetophenone on the basis of the following spectral properties: mp 187.6-188.9°C; IR (KBr) 2800-3300, 1690, 1600, 1160, 1020, 820, 675, and 560 cm^{-1}; NMR

(DMSO, 200 MHz) δ 2.27 (s, 3H), 3.85 (s, 3H), 4.52 (s, 2H), 7.10 (d, 4H, J-7.8 Hz), 7.46 (d, 2H, J=8.4 Hz), 7.98 (d, 2H, J=9.2 Hz), 8.08-8.22 (s, 3H).

Synthesis of 4-Carbethoxy-2-(4'-methoxyphenacyl)-3-(4'-methoxyphenyl)pyrrole (3).

0.50 g (1.89 mmol) of vinylogous amide (4) and 0.64 g (1.89 mmol) of amino ketone *p*TSA salt (5a) were dissolved in 50 ml of ethanol and allowed to stir and reflux under an inert atmosphere for 48 hours. The reaction was cooled to room temperature and the solvent was removed under reduced pressure. The resulting light brown solid product was redissolved in chloroform and washed with saturated sodium bicarbonate solution (2 x 100 ml). The organic layer was separated and dried over anhydrous magnesium sulfate. Concentration of the solution under reduced pressure yielded 0.42 g (55.9%) of an oily solid which was identified by TLC as not being either of the starting materials and by crude NMR as vinylogous amide (10). Without purification, the solid was redissolved in 100 ml of ethanol, 0.253 g (1.33 mmol) of *p*TSA was added, and the solution stirred at reflux for 10 hrs. After cooling, the reaction was concentrated under reduced pressure, dissolved in 100 ml of chloroform, and washed saturated sodium bicarbonate solution (2 x 50 ml). The organic layer was dried over anhydrous magnesium sulfate and concentrated under reduced pressure. Chromatography of the crude product with 25% ethyl acetate-75% hexane afforded 0.11 g (14.5%) of a yellow solid that was identified as 4-carbethoxy-2-(4'-methoxyphenacyl)-3-(4'-methoxyphenyl)pyrrole (3) on the basis of the following spectral properties: mp 124.0-127.2°C; IR (KBr) 3280, 1680, 1600, 1250, 900, 830, 600 cm^{-1}; NMR (CDCl$_3$, 200 MHz) δ 1.22 (t, 3H, J=7.0 Hz), 3.71 (s, 3H), 3.73 (s, 3H), 4.19 (q, 2H, J=7.0 Hz), 6.53 (d, 2H, J=8.8 Hz), 6.61 (d, 2H, J=9.2 Hz), 7.03 (d, 2H, J=8.8 Hz), 7.36 (d, 2H, J=9.2 Hz), 7.72 (d, 1H, J=3.2 Hz), and 10.0-10.2 (bs, 1H).

Thomas R. Cundari

The design of more effective insulin mimetic agents remains a goal of diabetes research. Vanadyl complexes show promise as effective anitdiabetic drugs, but at present predicting the compounds which will be most effective insulin mimetics by experiment is costly and inefficient. The object of this research was to develop computational methods to accurately and efficiently predict the structure of vanadyl complexes. Once established, the computational method enabled structure-function studies to be done on vanadium drugs. Overlays of theory versus experiment structures affirm that modeling vanadium insulin mimetics may be carried out with reasonable accuracy. Analysis revealed maximum activity of vanadium drugs with a volume of 500 A^3.

BACKGROUND

The design of more effective insulin mimetic agents remains a goal of diabetes research.[1] One group of compounds that show promise as effective insulin-mimicking compounds contain the metal vanadium.[2] Specifically, vanadyl (VO^{+2}) compounds stimulate glucose oxidation in rat adipocytes and lower blood glucose levels in diabetic rats.[3] The advantages of such drugs include oral administration and a minimization of long-term health problems common to diabetic patients such as cardiac and circulatory problems, visual difficulties, and premature death.

The efficacy of vanadium drugs is sensitive to the vanadium metal and its attached ligands.[4] However, no rational basis for selection of optimal ligands exists at present. Drug companies that presently test over 10,000 compounds a year would be able to study the complexes most likely to be the best insulin-mimetic compounds first. This eliminates costly and inefficient experimental work by prioritizing compounds that will be studied. It is highly desirable, therefore, to use computers to model chemical interactions, predict shape, and determine pharmacological properties of drugs before synthesizing the compound in the lab. In addition, once one understands what chemical properties contribute to the drug's effectiveness, the efficacy of drugs may be increased by changing the various components of the chemical. Altering the drug to increase water solubility is an example of a method to make drugs more effective with less side effects.

Past research has been done by the Cundari group on modeling related vanadium compounds called pervanadates.[5] These complexes include a central vanadium molecule in the (+5) oxidation state and two attached peroxy ligands; a typical example is shown in Figure 1. The vanadium metal, in addition to the attached ligands which surround it, in pervanadates is responsible for a large portion of their activity.[4] The objects of the present study are vanadyl complexes which are characterized by the vanadium in the (+4) oxidation state and an oxide ligand; a typical vanadyl complex is shown in Figure 2. Both pervanadates and vanadyl complexes have been shown to be potent insulin mimetics by increasing glucose oxidation, reducing blood glucose levels, and inhibiting protein tyrosine phosphatase (PTP).[4]

16

Finally, computational studies at the University of Memphis complement experimental studies of vanadium compounds being performed at Mississippi State University. It is the goal of this combined effort to develop greater insight into the design of more effective vanadium-based anti-diabetic drugs. Computer-aided design of many drugs is now a reality, however this has not yet been achieved for metal-containing drugs due to the difficulties in computer modeling of metal chemistry.

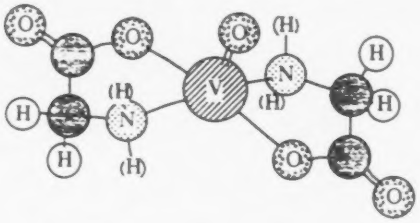

Figure 2: Vanadyl Complex with Glycine Ancillary Ligands.

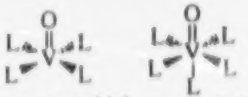
HYPOTHESIS

The objective of this research is to develop computational methods to accurately predict the structure of vanadyl complexes in an efficient manner. Once the computational model is validated by comparison with existing experimental data, the information obtained by computation will be used to identify new antidiabetics. By establishing a computational method, one is able to perform structure-function studies on vanadium drugs. The primary focus of this research will be on compounds with coordinated amino acids and related ligands because of their steric bulk, hydrophilicity, and chirality, properties which have been shown to determine insulin mimic ability. Furthermore, since amino acids are naturally occurring compounds, there is reduced possibility of toxic side effects if they are incorporated into antidiabetic drugs.

METHODOLOGY

Vanadium, a transition metal, gives vanadyl complexes a chemical diversity that is very challenging for computer modeling.[2] However, the accuracy of the computer models of vanadyl compounds can be checked by comparing calculated geometric data to that of published experimental results.[6] This allows one to develop a thoroughly validated computational model with which to study the properties of new compounds.

Vanadyl compounds to be studied are of the form L_nVO with vanadium in the +4 formal oxidation state; L_n signifies the ligand(s) which are attached to the vanadyl species. Complexes with four ancillary ligands (n = 4) are square pyramidal, while complexes with five ancillary ligands ($n = 5$) are octahedral, Figure 3. Biologically significant ligands to be studied are amino acids and other nitrogen and oxygen-based ligands since these form stable compounds with vanadyl.



square pyramidal   octahedral

Figure 3: Prototypical Vanadyl Structural Types.

Standard molecular mechanics programs (MM) which have been modified in our lab for vanadyl complexes are used to draw the preliminary sketch of the target complex and optimize its geometry.[7] A basic MM force field is given by equation 1.

$$U_{steric} = U_r + U_q + U_t + U_{vdw} \qquad (1)$$

Molecular mechanics is a simple ball-and-spring model of chemical systems, where the balls represent the atoms and the bonds are represented by springs. U_r describes the amount of energy needed to compress and stretch the bond between two atoms. U_Θ is the energy required to increase and decrease a bond angle formed by three atoms. U_τ is the amount of energy required to rotate about an individual bond or spring. Lastly, U_{vdw} describes the strength of the interaction between atoms which are not directly chemically bonded to each other. The optimum geometry of a drug is the combination of bond lengths, bond angles, etc. with the lowest steric energy (U).

There is no guarantee that the first structure sketched in is the lowest energy structure. Therefore, molecular dynamics (MD) is used to search for different low energy geometries by simulated annealing of a compound by heating it up to high temperatures (500 - 1000 K), and then cooling the drug back down to 0 K. The MD procedure begins with a rough sketch of the drug's conformation. The preliminary geometry is heated up allowing the atoms to freely move about. The drug is then allowed to cool. As a result of the continual heating up and then cooling down of the drug, one should be able to obtain the lowest energy (i. e., naturally occurring) geometry. Approximately fifty simulated annealing cycles (heating up followed by cooling down) are run to search for the lowest energy geometry. We have found this approach allows us to consistently determine the structure of metal-containing drugs. The simulated annealing process is depicted graphically in Figure 4.

RESULTS AND DISCUSSION

Based on preliminary theory-experiment data, we conclude that quantum mechanical calculation of molecular mechanical parameters for vanadium insulin mimics may be carried out with reasonable accuracy. To provide graphical proof that molecular mechanics can be used to accurately calculate geometries of vanadium insulin mimetics, computer generated models can be overlaid with experimental geometries. These overlays affirm that computational methods for prediction of vanadium complexes are accurate. Vanadium dioxo dioxalate and vanadium dioxo s-peida are just two examples of nearly twenty vanadyl drugs whose theory-experimental overlay shows good agreement. These examples are shown in Figure 5 and Figure 6.

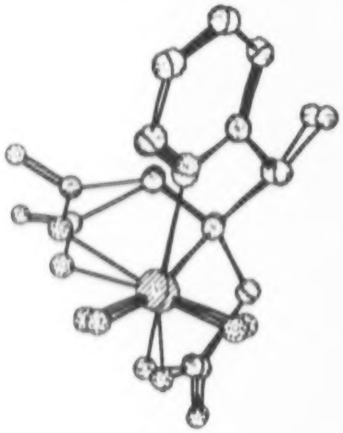

Figure 6: Overlap of Experimental and Predicted Geometries of V^{+5} Dioxo S-peida

Furthermore, the speed with which molecular mechanics may be applied to metal complexes is very fast. What takes many days to generate on a high performance computer using previously developed methods now takes only six seconds with comparable accuracy on a Macintosh personal computer using the MM methods developed in our lab. In addition the MM-predicted structures are as accurate, if not more accurate, than previous methods.

Now that the accuracy of the MM method has been demonstrated by comparison with known experimental systems, it is now possible to employ this computational model with good confidence for the study of novel vanadyl antidiabetics. In previous research from our group,[5] a quantitative structure activity relationship was developed by plotting the inhibition of PTP (a measure of antidiabetic drug activity)[4b] with molecular volume of the drug. The correlation suggests that there is maximum activity of vanadium drugs with a volume of ≈ 500 Å^3. Perhaps this is due to the chemical interactions between the vanadium drug and the drug receptor site. A nice illustration of this relationship between size and efficacy is the lock and key hypothesis. The drug must fit inside the substrate just as a key fits inside a lock; thus, size greatly affects activity. It is of interest in the future to investigate relationships between drug activity and other chemical properties such as hydrophilicity (which determines solubility in water) and chirality (related to the three-dimensional shape of the drug). These properties, along with size, have been shown by experimentalists to be important determinants of antidiabetic activity.

Other future work will include exploring further this relationship between activity and volume. In addition, potential vanadium drugs must be limited to those that are stable in the acidic environment of the stomach. Systems that meet this criteria will be isolated. Acid stability and the other chemical properties mentioned are intimately related to the structure of the drug, and hence accurate prediction of this property is paramount. Our preliminary results are therefore very encouraging in this regard.

ACKNOWLEDGMENTS

Faculty Advisor: Christopher K. Ober

ABSTRACT

Liquid crystalline networks combine the high dimensional stability typical of thermoset networks with the electrical and mechanical orientability of liquid crystals, allowing vastly different properties in the parallel or perpendicular directions of thin films to be locked-in upon curing to form a network. Accordingly, mixtures of a mesogenic dicyanate (DCN), bis(4-hydroxy-methyl-phenyl)terephthalate, and a commercially available thermosetting monomer, bisphenol-A-dicyanate (AroCy B10), were studied for curing behavior by polarized light optical microscopy. It was found that the time to the start of nematic phase development is an exponential function of curing temperature and seems independent of mixture composition. Remarkably, it was also found that mixtures containing up to 90 mol% B10 in DCN formed liquid crystalline mixtures capable of uniaxial orientation by magnetic or electric field alignment.

INTRODUCTION

Recently there has been a growing interest in the preparation and characterization of liquid crystalline (LC) networks. Such networks provide both the high dimensional stability and mechanical orientibility typical of polymer networks and the unique anisotropic behavior of LC materials. LC networks with a high degree of crosslinking further offer favorable properties for nonlinear optics and electronic packaging. Specifically, great interest has been shown in the use of LC networks as thermosetting resins for circuit board fabrication. For this use, such a network should combine the excellent thermal stability and dielectric properties that make cyanate esters very attractive in this area. In addition, the LC character allows such networks to be oriented either by electric field or surface alignment. Furthermore, because LC thermosets are transparent to microwave radiation, they can be used as the base material for radar apparatus, while their light weight, high impact resistance, and chemical stability make them very attractive materials for aircraft structures.

The use of thermosetting LC networks opens the possibility for selective orientation and subsequent "locking-in" of different structures, providing very different physical and chemical properties in select regions. Mesogens can be aligned prior to curing through the use of an electric field on the order of 1 V/μm. In addition, the cross-linked network retains locked-in orientations up to 100°C above the glass transition temperature.

A mesogenic dicyanate (DCN) of *bis(4-hydroxy-methyl-phenyl)terephthalate* shown in Figure 1a, was used as reported elsewhere[1]. The thermosetting agent used is a commercially available monomer, bisphenol-A dicyanate (AroCy B10), shown in Figure 1b.

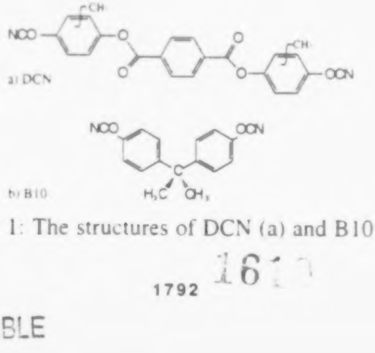

Figure 1: The structures of DCN (a) and B10 (b)

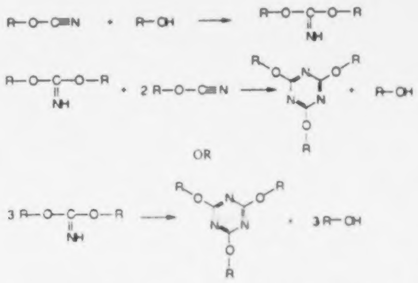
BEST COPY AVAILABLE

When DCN and B10 are dissolved in chloroform or dichloromethane, and the precipitate is dried and cured, a cyclotrimerization of the cyanate groups form a compact, six-membered triazine ring at each cross-link site on heating. Possible mechanisms for such a reaction[2] are shown below in Figure 2.



R—O—C≡N + R—OH ⟶ R—O—C(=NH)—O—R
R—O—C(=NH)—O—R + 2 R—O—C≡N ⟶ + R—OH
OR
3 R—O—C(=NH)—O—R ⟶ + 3 R—OH

Figure 2: Suggested mechanisms for the formation of triazines

It has been estimated that the cured compound will remain liquid crystalline up to 20 mol% B10 in the mixture[3]. The actual saturation value is of great interest, however, as often a balance between the thermosetting properties of B10 and the liquid crystallinity of DCN is desired.

Another variable in the curing reaction is the temperature at which the reaction is carried out. It has been estimated that the curing will continue to completion for temperatures in the range of 180°C to 240°C[4]. As expected, higher curing temperatures lead to a shorter LC phase induction time due to the increased kinetic energy driving the reaction.

This paper will present evidence showing that mixtures of DCN and B10 could be liquid crystalline up to 90 mol% B10 in DCN. Polarizing optical microscopy observations show that high B10 mixtures are in many cases indistinguishable from low B10 mixtures after curing and that mixtures containing up to 90% B10 become liquid crystalline and show a vivid Schlieren texture. In addition, the curing reaction was monitored for mixtures of B10 and DCN and analyzed for the start of nematic phase development as a function of curing temperature and mixture composition. It was found that composition does not affect the nematic phase induction time whereas there is an exponential relationship with curing temperature.

EXPERIMENTAL SECTION

DCN was provided by Hilmar Korner, who synthesized *bis(4-hydroxy-methyl-phenyl)-terephthalate* as reported elsewhere[1,5]. AroCy B10, bisphenol-A dicyanate, was kindly provided by IBM Endicott and used without further purification.

Mixtures of DCN and B10 were made by weighing the appropriate amount of DCN and B10 to total 200 mg into glass vials and adding excess chloroform or dichloromethane. The mass of DCN, m_{DCN}, to be added to make a mixture of total mass 200 mg and of mole fraction of B10 X_{B10} is given by (1) where the molar mass of DCN is 428 g/mol and B10 is 278 g/mol.

$$m_{DCN} = \frac{(0.200\mathrm{g})\left(428\frac{\mathrm{g}}{\mathrm{mol}}\right)(1 - X_{B10})}{\left(278\frac{\mathrm{g}}{\mathrm{mol}}\right)(X_{B10}) + \left(428\frac{\mathrm{g}}{\mathrm{mol}}\right)(1 - X_{B10})} \quad (1)$$

Samples analyzed for the curing reaction were taken as flakes of dried precipitate from solution. The flakes were placed on cleaned glass slides without cover-slip and heated in a Mettler FP-82 hotstage. Light intensity data was collected as a measure of sample birefringence by a Mettler 17517 photomonitor in an eyepiece of a Nikon *Optiphot2-Pol* polarizing optical microscope (POM) at 50x magnification. Data was collected with a custom program written for LabView.

Samples prepared solely for the purpose of determining liquid crystallinity were prepared from droplets of solution on glass slides, also without cover-slip so as to reduce external stress on the samples. The slides were all cured on a hot-plate at 200°C ± 5°C for 1 h and were examined at room temperature by POM. Color photographs were taken on Kodak color film by a 35 mm Nikon camera attachment on the microscope.

Flake and solution deposited film compositions were compared by Fourier transform infrared spectroscopy (FT/IR) using a Mattson 2020 Galaxy Series FT/IR.

RESULTS AND DISCUSSION

Curing Behavior of the Mixtures

As samples are heated it is observed the transmitted polarized light intensity increases briefly on melting but remains near zero until the start of nematic phase development, t_s, measured in minutes. Subsequently the whole sample becomes birefringent and the light intensity reaches a maximum after t_e minutes. In general, the light intensity varies with time as shown in Figure 3.

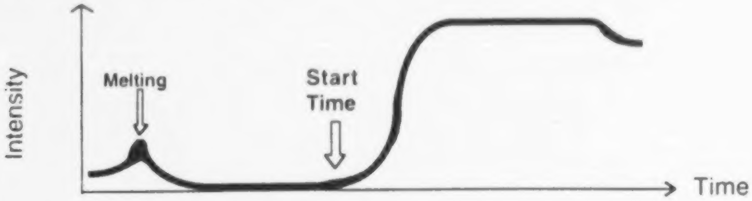


Figure 3: Sample birefringence at high temperature

Figure 4 shows the results of the tests, averaging points at the same temperature, for the start of the nematic phase development at various curing temperatures. The end time versus T gives similar results.

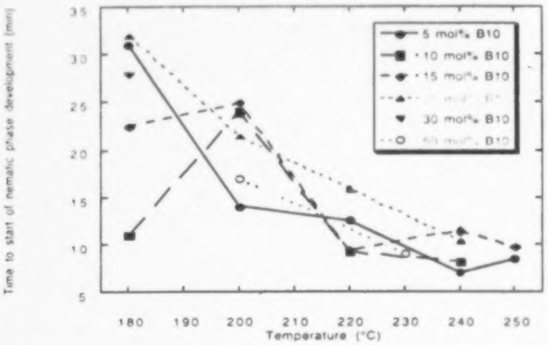

Figure 4: Relationship between time to start of nematic phase development and curing temperature

It is clear from the graph that there exists an exponential relationship between curing temperature and time to the start of nematic phase development. However, Figure 4 also indicates that there is no clear relationship between composition and either variable. Figures 5 separates estimates an exponential relationship between time and temperature by fitting a linear relationship to ln(t) versus 1/T

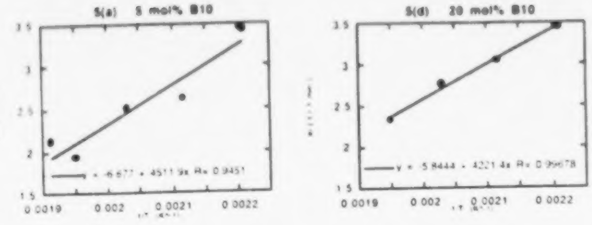

Figure 5: Arrhenius plots showing the exponential relationship between time and temperature for 5 mol% B10 and 20 mol% B10 mixtures.

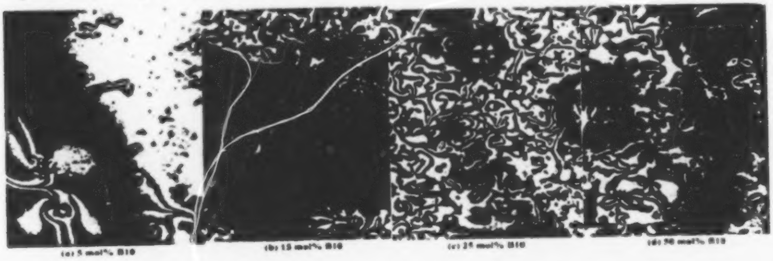
The slope of the extrapolated lines in Figure 5 is directly related to the activation energy for network formation. It is clear that the 20 mol% sample has a smaller slope and thus a smaller activation energy associated with it than the 5 mol% sample. However, samples of other compositions do not show this same trend. This may indicate that further testing is required while more vigorously controlling sample dimensions.

Liquid Crystallinity of B10/DCN Mixtures

It was predicted that B10/DCN mixtures would be liquid crystalline only up to 20 mol% B10[1] and the observation of a LC phase up to 50 mol% B10 raised the question of how much B10 can be added to the LC DCN in order for the mixture to remain LC. Solutions were made in increments of 5 mol% B10 and the films were cured for later examination by POM. It is clear from such observations that films of up to 90 mol% B10, but less than 95 mol% B10, are LC and show a clear Schlieren texture.

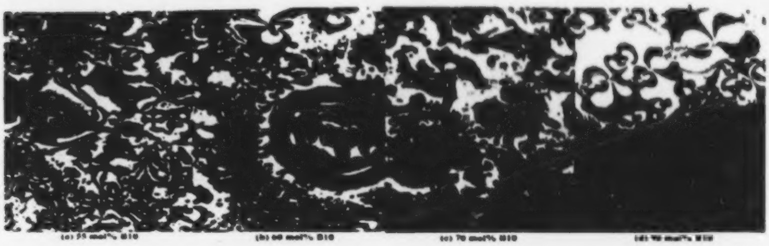
There are differences, however, between samples with low B10 content and those with more B10 than DCN. To be sure, these differences may be due to variations in film thickness as all solutions of more than 50 mol% B10 were made with dichloromethane, while those of less than 50 mol% B10 were made with chloroform simply because those solvents were available at the time the solutions were made. Because dichloromethane has a larger vapor pressure than chloroform, the films deposited from the former solution could be thinner than those from chloroform. As the color of LC samples is primarily a thickness effect, the less vibrant color of higher B10 samples may be explained by the possibly thinner films made from dichloromethane solution.



(a) 5 mol% B10 (b) 15 mol% B10 (c) 25 mol% B10 (d) 50 mol% B10

Figure 6: LC mixtures prepared from chloroform solution

Figure 6 shows photographs taken at room temperature of 5, 15, 25, 50 mol% B10 while figure 7 shows 55, 60, 70, and 90 mol% B10. It is interesting to note how similar 25 mol% B10 and 50 mol% B10 look (both from chloroform solution) and how different 50 mol% B10 is from 55 mol% B10 (the later from dichloromethane).



(a) 55 mol% B10 (b) 60 mol% B10 (c) 70 mol% B10 (d) 90 mol% B10

Figure 7: LC mixtures prepared from dichloromethane solution

Some samples were noted to develop a feathered, brushed texture on the surface. It is possible that there is a crystalline phase developing on the surface. Wide angle x-ray diffraction testing of the mixtures failed to show any sharp peaks. Rather, the broad and diffuse pattern is indicative of an amorphous or LC structure.

CONCLUSION & FUTURE WORK

Mixtures of a thermosetting monomer B10 and a mesogenic dicyanate DCN were analyzed for the time to start of LC formation as a function of curing temperature. It was found that there exists an exponential relationship between the time to the start of LC formation and the curing temperature, though there is no clear relationship at this time between either variable and mixture composition.

Mixtures were also examined for the presence of an LC phase by POM. It was found that samples of up to and including 90 mol% B10 in DCN appear liquid crystalline. Some samples developed a feathered texture on the surface which may indicate the presence of a crystalline phase. Synchrotron x-ray diffraction will be used to test this. In addition, solid state NMR will be used to determine if curing mixtures are LC entirely or are phase separating, as exposure to high-intensity electric or magnetic fields will align LC samples.

Continuing investigation into the liquid crystallinity of low mesogen concentration mixtures will continue to develop the theory behind LC formation as well as many possible industrial end-uses, allowing more efficient production of LC thermosetting resins and a fuller understanding of their properties.

INTRODUCTION

Faraday rotation experiments on the sodium salt of 2-napthoic acid doped in polyvinylalcohol (PVA) films have been employed to explore the paramagnetic properties of its excited triplet state. To the best of our knowledge Faraday rotation data for an excited electronic state of an organic molecule has not previously been reported in the literature.

The most unique feature of the 2-naphthoate/PVA system is the observed room temperature phosphorescence. Previous research on 2-naphthoate salts adsorbed on cellulose paper support has shown the experimentally determined lifetime of the triplet state to be in the range of 0.5 to 1.0 seconds at room temperature.[1] The observed room temperature phosphorescence is due to the strong hydrogen bonding interaction between the hydroxylic sites on the polymer backbone of the host and the delocalized negative charge on the carboxyl group of the 2-naphthoate salt (Figure 1). The hydrogen bonding greatly reduces the movement of the 2-naphthoate, which hinders the motional quenching of the triplet state[2] and allows for room temperature phosphorescence data to be obtained. In order to measure phosphorescence, photochemists usually have to cool the sample to liquid nitrogen temperatures to form a rigid glass, which reduces collisional effects. The hydrogen bonding environment in the PVA host provides a rigid environment at room temperature, which is similar to the environment found in the low temperature glasses.[1] The unusually long lifetimes of the triplet state, which result from the environment the host provides, make it possible to obtain relatively large steady state populations of the paramagnetic state making it possible to probe the system with Faraday rotation. The transparent nature of the PVA film in the region of visible light also makes it a good host matrix for Faraday rotation measurements.

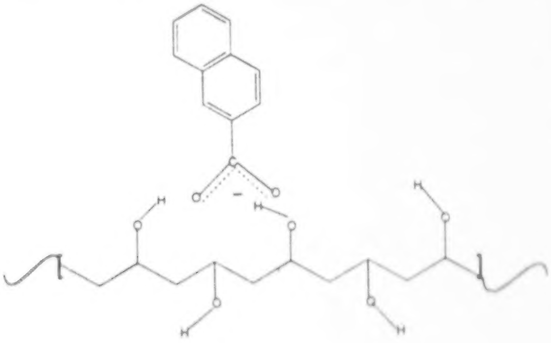

Figure 1. The hydrogen bonding interaction between the 2-naphthoate salt and the hydroxylic sites in the PVA polymer backbone.

Faraday rotation is the amount of rotation detected when a plane of linearly polarized light is rotated by passing through a sample in the direction of a magnetic field. Microscopically, the rotation is created by the unequal splitting of the ground or excited state energy levels due to the applied magnetic field. This rotation is described by[3]

$$\Theta_r = VHL \qquad (1)$$

where V is the Verdet constant (in degrees $gauss^{-1}$ cm^{-1}), H is the magnetic field strength (in gauss), and L is the sample length (in cm) The Verdet constant (V) is a proportionality constant which generally increases as the wavelength of plane polarized light approaches the fundamental absorption wavelength of the sample of interest[3] The magnitude of the Verdet constant is effected by several inherent properties of the sample These properties include the maximum concentration density, the refractive index, and the transition matrix elements[3,4] Since the amount of rotation is directly proportional to the length of light transversing the sample, a longer sample length would normally be desirable In this case, however, the sample thickness also needs to be optimized in regards to generating the excited naphthoate molecules in the sample with an ultraviolet light source

According to Weber[3], the Verdet constant of a diamagnetic substance is determined by

$$V_{dia} = 4\pi^2 N v^2 \sum_b \frac{P(a,b)}{(v^2 - v_{ab}^2)^2} \qquad (2)$$

where V is the frequency of the probe laser, V_{ab} is the electronic absorption wavelength of the sample, N is the number of sample molecules and P(a,b) is a electronic transition matrix element

For paramagnetic molecular systems the Verdet constant is[3,4]

$$V_{para} = \frac{4\pi^2 v^2 \chi}{g\beta ch} \sum_{a,b} \frac{P(ab)}{v^2 - v_{ab}^2} \qquad (3)$$

where β is the electronic Bohr magneton, g is the electron g-value, and χ is the magnetic susceptibility of the sample The other constants have their usual meaning For paramagnetic species χ depends on temperature as[5]

$$\chi = \frac{C}{3kT} \qquad (4)$$

where C is the Curie constant for a specific sample, T is the absolute temperature, and k is Boltzmann's constant As a result, the Verdet constant for paramagnetic species in a sample matrix can be increased by lowering the temperature, while V for the diamagnetic species would remain unchanged

The presence of a rotation of plane polarized light by the triplet state can be described by the effects of the magnetic field on the triplet sublevels In the presence of a magnetic field the triplet state is split into three states with projections of the magnetic moment along the field of $1h\ 2\pi$, $0h\ 2\pi$, and $-1h\ 2\pi$, respectively The contribution of each state to the optical rotation is obtained by dividing the interaction energy by the corresponding excitation energy[4] Even though the interaction energies of the two triplet states with magnitudes $1h\ 2\pi$ and $-1h\ 2\pi$ are equal but opposite in sign, the corresponding excitation energies are slightly different so that the total rotation caused by the three triplet sublevels is different from zero[4] As a result, Faraday rotation data for the excited triplet state of 2-naphthoate has the potential to yield information about the relative energies of the triplet sublevels as well as their populations Information about the triplet sublevel energies and relative populations for 2-naphthoate in the PVA host can be used to learn about the physical properties of the polymer host This data may also serve as a useful experimental model of the excited triplet states of the naphthalene ring system, which is an important paramagnetic probe system used in many recent studies[6,7]

EXPERIMENTAL

Sample Preparation

Naphthoic acid was purchased from Aldrich and purified by fractional vacuum sublimation. The purified acid was then dissolved at an appropriate concentration in standard NaOH solutions. Aliquots of the NaOH solutions were then added to a solution of 99% hydrolyzed 105-110 kdal PVA from Baker dissolved in hot water. The resulting solutions were rotoevaporated to a viscous paste and caste into a film well. Typically films were dried under nitrogen gas for several hours and then left to dry overnight in a vacuum desiccator. The optimum sample dimensions for the Faraday rotation experiment were determined to be a film of 1cm long (along the axis of the Faraday laser probe) and 0.05 cm thick (along the axis of the UV lamp source) at a naphthoate concentration of 2.5 mM. The optimum film thickness and concentration for UV excitation were based on the absorption coefficient for the naphthoate salt at the excitation wavelength.

Phosphorescence Decay Measurements

Phosphorescence decay data was measured with a Lambda Physik M2000 pulsed-nitrogen laser exciting the PVA sample with a 337 nm pulse (4.5 ns in width at ca. 8mJ/pulse). The subsequent emission was recorded from emitted sample light which was focused onto a Hitachi 139 photomultiplier tube (PMT) ($\tau_{RC} < 0.1$ μs). The PMT output voltage was signal averaged on a Tektronix 2221A 100MHz digital oscilloscope with 1 K of data points. The timing of each decay acquisition was controlled by a Keithly System 570 data acquisition workstation which triggered the acquisition of the PMT signal on the scope at ca. 20 ms after triggering the laser pulse in order to avoid averaging any signal from scattered laser light or fluorescence. The room temperature measurements were made inside of an optical cryostat with the sample bathed in room temperature dry nitrogen gas. The low temperature measurements were obtained in the same cryostat with the sample immersed in liquid nitrogen at 77 K.

Faraday Rotation Measurements

The experimental apparatus that was used for Faraday rotation measurements is a modified version of a design described in previous work.[8] A helium-neon laser generates electromagnetic radiation at a wavelength of 630 nm. The resulting light is optically chopped at a lock-in reference frequency of 210 cycles/sec to reduce any external noise received by the detector. The light travels through a plane polarizer and then through a hole bore into the electromagnet where it encounters the sample. The magnetic field strength was measured with a Rawson-Lush rotating coil gaussmeter. The sample is placed between the poles of the electromagnet in a fused quartz dewar. The dewar is connected to a heat exchanger which is filled with liquid nitrogen. Dry nitrogen gas is pumped through the coil in the bottom of the heat exchanger and the cold nitrogen gas is blown over the sample in the dewar. The dewar can also be filled with liquid nitrogen in order to work at 77 K. After the plane polarized light leaves the opposite pole of the magnet it transverses another plane polarizer which is connected to a stepper motor. The stepper motor increases the angle of polarization by 1° at which point the intensity of the light is detected via lock-in amplification and recorded. The paramagnetic triplet state of the 2-naphthoate salt was generated by irradiating the sample perpendicular to the magnetic field direction with a Spectral Energy 500W Hg lamp fitted with a, water filter, 320 nm band pass filter, and a 1 m Oriel light pipe. The polarizer rotates 360° and a computer program records the intensities which are then fitted to a cosine squared curve. A second program computes the angular shift difference between the two minimum values of the curve. The curve is then plotted and analyzed.

DATA ANALYSIS

The phosphorescence decay data at room temperature and 77 K was transferred from the digital scope to a computer and fit to a simple monoexponential decay. The best fit to the decay data at room temperature produced a lifetime $\tau = 1.25 \pm 0.05$ s (where τ is the 1/e time). The best fit of the data at 77 K resulted in $\tau = 1.19 \pm 0.05$ s. A typical room temperature decay is shown in Figure 2.

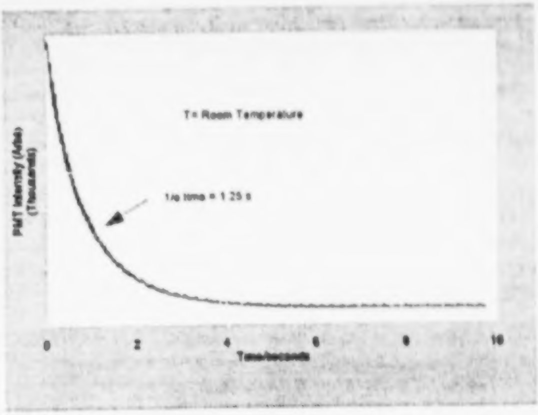

Figure 2. Room temperature phosphorescence decay of 2.5 mM 2-naphthoate in a PVA film.

To determine the faraday rotation of the paramagnetic species, two successive runs were performed both with an applied magnetic field, however, during one run the sample was irradiated with ultraviolet light and during the other run the sample was not irradiated. So the resulting spectra compared the rotation due to the diamagnetic ground state of 2-naphthoate and the paramagnetic triplet state of 2-naphthoate. The rotation spectra acquired with the UV lamp on and off at room temperature showed no observable change in the Faraday rotation due to the paramagnetic triplet state, which is present when the lamp is on. By cooling the samples we expected the value of χ in Equation 3 to increase in magnitude thereby increasing the Verdet constant for the paramagnetic state relative to the diamagnetic state and increasing the observed relative magnetic rotation. The rotation spectra acquired with the UV lamp on and off at 77 K produce a measurable change in rotation of 3.05° ± 0.01°. The Faraday rotation data for the doped PVA sample at 77K is shown in Figure 3.

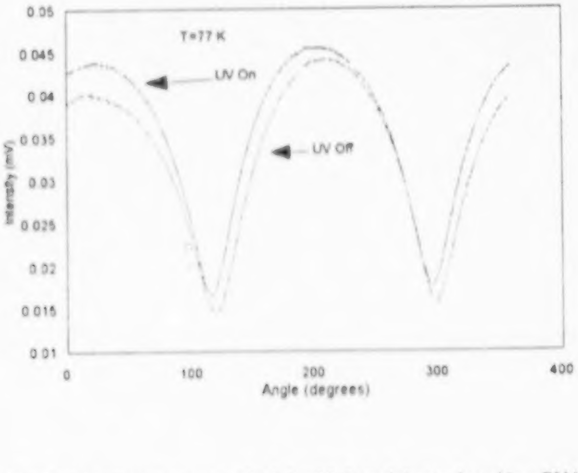

Figure 3. The Faraday rotation spectra for 2.5 mM 2-naphthoate doped in a PVA film at 77 K.

DISCUSSION

The experimental lifetimes of 2-naphthoate in PVA film at room temperature are in agreement with what is known in the literature for 2-naphthoate on paper support.[1] Clearly the PVA film is providing an environment which is as rigid as the paper host for the naphthoate salt. The fact that τ does not change significantly in going from room temperature to 77 K indicates that the rigid nature of the PVA host has not changed in regards to restricting the motion of the probe molecule. Apparently, the hydrogen bonding interactions between the salt and the PVA film are so dominant that any changes in the polymer density with temperature are relatively insignificant.

Using Equation 1 the Verdet constant was calculated to be .10±0.05 minutes/(gauss cm). Although there is no precedent in the literature to compare this result to, literature values for the Verdet constant of similar diamagnetic organic molecules are ca. five orders of magnitude larger for the neat solids.[9] The dilute concentration of the naphthoate salt can account for ca. 3-4 orders of magnitude difference in the Verdet constant, which reflects a steady-state population of the excited triplet state of 1% to 10% of the ground state. This is at least reasonable.

In Figure 3 the intensities of the non-irradiated spectrum and the irradiated spectrum are different. The extinction angles do not reach zero on the intensity scale. Possible explanations may be that either scattering of the laser light was occurring in the polymer medium or that the light had become elliptically polarized. Elliptical polarization occurs because of unequal absorption by the medium of the left and right components of circularly polarized light resulting in some amount of probing light reaching the detector at the extinction angles. It is probable that both of these explanations occurred because each comparative run was accomplished with the sample in the same location.

ACKNOWLEDGEMENTS

The authors would like to thank Ms. Meagan Doody for her assistance in making some of the Faraday rotation measurements and Mr. RJ Sucharski for his assistance in making some of the Phosphorescence decay measurements. We also acknowledge the Morris Fellowship for Undergraduate Research at SUNY Brockport and the NSF for its support of this project under grant DUE9452265.

Dr. J.R. Stephens

Valproic acid(VPA) is an anticonvolsant drug that is associated with a rare, but serious liver toxicity. It has been suggested that a prodromal infection may play a role in the development of this hepatotoxicity. Recent studies in rats have shown that VPA increases the lethal toxicity associated with bacterial endotoxin(LPS) and tumor necrosis factor(TNF). Eicosanoids, prostaglandins and leukotrienes, are known mediators of the normal response to an infectious illness. An on-line extraction, reverse phase high-performance liquid chromatography (HPLC) procedure has been developed to investigate the hypothesis that eiconsanoid concentrations are altered by treatment with combinations of VPA and TNF. Rat eicosanoid production is altered by *in vivo* treatment with VPA, TNF, and VPA-TNF combinations. Future studies will investigate the effects of VPA and TNF on eicosanoid production in rats.

INTRODUCTION

Valproic acid(VPA) is an anticonvulsant drug associated with a rare but serious human liver toxicity syndrome. It has been suggested that a prodromal infection may play a role in the development of this hepatotoxicity. Recent studies in rats have shown that VPA increases the lethal toxicity of bacteria endotoxin(LPS) and tumor necrosis factor(TNF). (Stephens et al, submitted for publication) Circulating endotoxins result in the release of eicosanoids, cell mediators, from blood cells, vascular endothelial cells, and smooth muscle cells. Eicosanoids are ubiquitous, potent vasoactive compounds with important cellular effects and most have one or more pathophysiologic effects consistent with involvement of mediators of circulatory shock and associated cardiovascular derangement. (Bottoms et al.,1995) An on-line extraction, reverse-phase HPLC procedure was developed to measure the changes in rat plasma concentrations of eicosanoids in response to treatment with VPA, TNF, and combinations of VPA and TNF.

OBJECTIVES

The objective of this work is to develop a technique which separates and measures eicosanoid standards using on-line extraction, reverse phase HPLC and to analyze eicosanoid concentrations in plasma obtained from Sprague-Dawley rats treated in-vivo with VPA, TNF or the combination of VPA and TNF.

METHOD

Sprague-Dawley rats were divided equally into four treatment mg/kg, i.p.) and TNF (17.5 mg/kg, i.v.) Blood samples were obtained 2 hours after treatment. Blood plasma was obtained by centrifugation and frozen at -20°. 200 µL of plasma from each sample were treated with 700 µL of MeOH, 4.0 mL of H_2O, and 100 µL CH_3CN:MeOH (1:1) containing 125 ng/mL of PGB_2. Following overnight storage at -20°, samples were centrifuged at 2000 g for 20 minutes. The supernatant was removed and immediately subjected to on-line extraction and HPLC analysis or placed at 4° until analysis.

The extraction column, a LICHROSPHERE RP-18 5 MICRON guard column, was equilibrated with 7.4 mL pre-wash solvent (2.5mM $H_3PO_{4(aq)}$:MeOH (85:15)). The 5 mL sample was pumped onto the extraction column with an Altex Model 110 A pump. The extraction column was washed with a total of 6 mL of pre-wash solvent. The sample was then injected onto the analytical column, LICHROSPHERE 100 RP-18 N-ENCPD 54 - 150mm x 4.6mm.

The initial HPLC conditions were 25% Solvent A (H_2O:CH_3CN:TFA, 70:30:0.04), 75% Solvent B (H_2O:CH_3CN:MeOH:TFA, 20:60:20:0.05) at a flow rate of 0.75 mL/min. A linear solvent gradient was run from 75% Solvent B to 100% Solvent B over 20 minutes. The detector wavelength, initially set at 280nm to detect prostaglandins and leukotrienes, was changed to 237nm at 15 minutes in order to detect HETEs. Data were collected for 25 minutes.

RESULTS

An on-line extraction, reverse phase HPLC procedure was designed which successfully separated seven eicosanoid standards, fig. 1. The procedure, based on one developed by Yu and Powell(1995), involved a 20 minute linear gradient and a lambda shift from 280nm to 237nm at the 15 minute mark. PGB_2, LTC_4, LTD_4 and LTE_4, absorbed at 280 nm and eluted at 7, 10.5, 12 and 12.9 minutes respectively. 5-hete, 12-hete and 15-hete, absorbed at 237nm and eluted at 17.4, 19.1 and 20.8 minutes respectively. Figure 2-5 displays eicosanoids present in the plasma of rats treated with saline, VPA, TNF and VPA-TNF. Changing concentrations of eicosanoids create a unique pattern for each treatment. Notably, peaks appear at 13.1, 21.6 and 22.3 in all rats treated with VPA or VPA and TNF relative to untreated rats. There is a significant increase in peak 10.8 among rats treated with TNF. Further, there is an increase in peak 10.8 between rats treated with TNF and VPA-TNF. Lastly, there is a notable difference in peak 4.1 between untreated rats and rats treated with TNF of VPA-TNF.

CONCLUSION

An on-line extraction, reverse phase HPLC technique was developed which successfully separated and measured seven eicosanoid standards.

Analysis of rat plasma samples suggest that rat eicosanoid production is altered by *in vivo* treatment with VPA, TNF and VPA-TNF. The variety of differences in eicosanoid concentrations provide enough information to warrant further investigation of the effects of VPA and TNF on eicosanoid production.

Susan C. Jackels

ABSTRACT

Macrocyclic ligand chemsitry has been a recent field of interest combining organic and inorganic chemistry. New and traditional techniques of organic synthesis have been derived to make a wide variety of macrocycles that can bind numerous cations. This study has focused on the iron chelating properties of a polyazamacrocycle with six nitrogen donors.

The synthesis and identification of an iron complex of (pyo)$_2$[18]dieneN$_6$. (3,6,14,17,23,24-hexaazatricyclo[17.3.1.]tetracosa-1(23),8,10,12(24),19,21-hexane) is reported. A previous synthesis was refined in which the complex was formed from reactions of pyo$_2$[18]dieneN$_6$ with iron(II) sulfate and was isolated as a sulfate salt. The spin and oxidation state of Fe were confirmed through magnetic susceptibility tests. Infrared spectra are consistent with the presence of ligand pyo$_2$[18]dieneN$_6$ in the complex. While the compound has yet to be obtained pure, preliminary elemental analysis results are consistent with the other characterization data. A discussion of future goals for the resolution of the enantiomers is included.

INTRODUCTION

Macrocyclic ligands that bind metals have several applications including metal extraction and modeling for metal binding proteins. Hemoglobin and chlorophyll are two examples of metal binding proteins that contain macrocyclic ligands. Stable macrocyclic ligands have also been used in medical imaging and chemotherapy.[1] The (pyo)$_2$[18]dieneN$_6$ ligand is of particular interest because when coordinated it has helical topology which is a fundamental structure in nature as seen in proteins and DNA.[2]

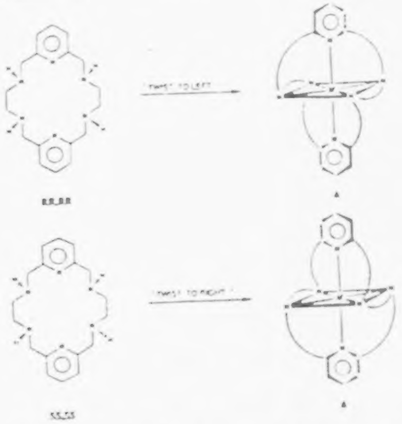

Figure 1. (pyo)$_2$[18]dieneN$_6$ isomers and the helical morphology of the enantiomers in the "right" and "left" octahedral wrap.

The polyaza macrocycle, $(pyo)_2[18]dieneN_6$, and its complexes with several metals have been synthesized and reported.[3] Polyaza macrocycles have recently received much attention; triaza and tetraaza macrocycles have been extensively studied in coordination chemistry and more recently macrocycles with N = 5 or 6 have been of interest, where N is the number of coordinating nitrogens.[4] $Pyo_2[18]dieneN_6$ is intriguing because it was found to bind a variety of metals, and in some cases more strongly than the closely related and previously studied $[18]aneN_6$.[3] Furthermore, the metal complexes found to have a unique structure.

The presence of pyridine rings is presumed to add stability to the coordination by contributing favorably to the enthalpy and entropy. Some possible explanations for these effects are detailed by Rothermel et al. The enthalpy of coordination might be favored due to the larger dipole moment of pyridine compared to secondary amines. Second, pyridine may relieve potential steric hindrance caused by ortho hydrogen atoms since it is connected to the macrocycle through the 2,6 position. Thirdly, the pyridine rings may preorganize the ligand for coordination by effecting a rigid structure.

The ability for this ligand to bind metals of varying sizes led to the hypothesis that the macrocycle could wrap and unwrap to accommodate differently sized cations. Rothermel et al. found that the planarity and rigidity produced by the two pyridine rings limited the structure to wrap only in the meridional mode. When bound to a metal, the $(pyo)_2[18]dieneN_6$ twists in Δ and Λ helical forms. This produced D_2 symmetry corresponding to a hexacoordinated pseudooctahedral wrap.[3] Bryant et al. measured the angle of wrap of the ligand bound to several different metals including alkaline earth, transition, and lanthanide metals. As predicted, the angle changed with the size of the metal.[7]

Since the ligand can twist in either of two directions it forms two enantiomers. Bryant et al. resolved the enantiomers by separating diastereomeric salts of barium (+)-tartrate. The resulting diastereomers were separated based on their differing solubilities.

Each metal introduces a unique chemistry. This current study continues the previous work by exploring the ligation of $(pyo)_2[18]dieneN_6$ with a new cation. This project investigates the synthesis and characterization of the macrocyclic iron complex, $[Fe((pyo)_2[18]dieneN_6)]^{2+}$, isolated as a bisulfate salt.

EXPERIMENTAL

The preparation of $(pyo)_2[18]dieneN_6$ was done according to published methods.[1,3] Chemicals were reagent grade and used as purchased.

Preparation of $[Fe((pyo)_2[18]dieneN_6)]^{2+}$

Equimolar amounts of $(pyo)_2[18]dieneN_6 \cdot H_2O$ and $FeSO_4 \cdot 7H_2O$ (0.745 mmol) were dissolved in anhydrous methanol(10 ml). The mixture was heated for 45 minutes during which color of the cloudy solution changed from a deep red to a reddish brown. Once the solution had cooled the reddish precipitate was collected through suction filtration, washed with cold MeOH and dried in a vacuum desiccator. The dried product was a rust color. (Yield, 24%)

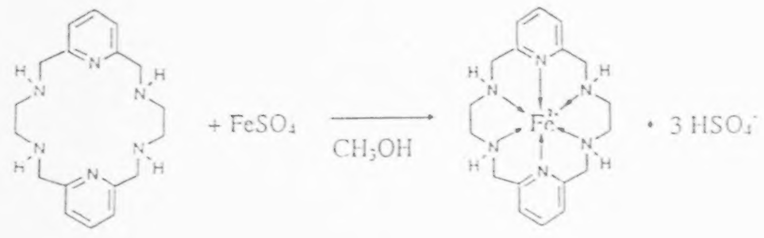

Figure 2. Synthesis of the iron complex

BEST COPY AVAILABLE

Infrared spectra were collected using a diffuse diffraction apparatus on a Perkin-Elmer Paragon 1000. The solid sample was mixed in KBr.

The Evans Balance was used for magnetic susceptibility measurements.

CHARACTERIZATION

The methods attempted for characterization of the product include IR spectroscopy, NMR spectroscopy, magnetic susceptibility, and elemental analysis.

Infrared spectral results. (KBr pellet, (cm-1)) v_{C-H} aromatic, 3146 (w); v_{C-H} aliphatic, 2939, $v_{C=N}$ and $v_{C=C}$ 1573, 1455, v_{SO} 1110 - 1130.

Proton nuclear magnetic resonance. The bands were broadened due to the paramagnetic effects of iron.

Magnetic susceptibility tests. The magnetic susceptibility, $X_g = 0.663 \times 10^{-6}$ cgs/g. To calculate the spin state, a correction for diamagnetic contribution of other atoms in the molecule is required. The result, X_A is used in determining a value for the spin state, $\mu_{eff} = 2.828(X_A T)^{1/2} =$ 0.86 BM. This number was compared to the known values for the spin states of iron.

DISCUSSION

Elemental analysis was not completed in this study due to difficulties in recrystallizing the product. The product which is either a sulfate or bisulfate salt was not soluble enough in any solvent for thorough recrystallization. This problem may also affect other results for the characterization of the salt.

In a previous unpublished study that attempted synthesis of the complex using ferrous sulfate or ferric sulfate, it was shown through magnetic susceptibility tests that the product form each synthesis was the same. An elemental analysis was attempted with the ferrous sulfate crude product. The results indicated that the product was most likely a tris-bisulfate salt. This would indicate that the iron was in the 3+ oxidation state.

Further evidence for the 3+ oxidation state and conclusion that the product is a tris-bisulfate salt is given by the yield results. In the preparation of $[Fe((pyo)_2[18]dieneN_6)]^{3+}$, the ratio of iron(II) to sulfate in the ferrous sulfate is 1:1. In the proposed tris-bisulfate product, the ratio of iron(III) to sulfate is 1:3. Therefore, at most one would expect a yield of 33% of the expected iron complexes since the limiting reagent is the bisulfate. The observed yield was around 24%. The iron is oxidized from 2+ to 3+ in the reaction, most likely by O_2 in the air. It is well known that iron(II) can be easily oxidized presence of oxygen. We did not attempt the reaction under an inert gas.

When NMR spectroscopy was attempted in the previous study the peaks were distorted. This is due to paramagnetism of the iron. To further study the magnetic moment of the iron, magnetic susceptibility measurements were made. The results indicated that the product was paramagnetic. If the Fe is in the 3+ state, then the results indicated that the spin state is low, so the iron(III) is in the t_2g^5 state. The number 0.86 BM is compared with known values for the spin states of iron(III). The range for low spin iron(+3) is 2.2 - 2.7 BM. The observed experimental value of 0.86 BM is somewhat lower than the accepted range and the discrepancy could be due to incomplete purification.

The reported IR results give evidence for the presence of the $(pyo)_2[18]dieneN_6$ ligand and the bisulfate salt.

The proposed 3+ oxidation state and low spin state for the iron is supported by the fact that iron prefers these states when in complexes with the strong chelating amines 2,2-dipyridil and 1,10-phenanthroline. Furthermore, the most stable binding state for iron(III) is octahedral. As discussed in the introduction the $(pyo)_2[18]dieneN_6$ ligand coordinates with the metal in a pseudooctahedral wrap.

CONCLUSIONS

The completed characterization tests indicate that the preparation of $[Fe((pyo)_2[18]dieneN_6)]^{3+}$ as a bisulfate salt was successful. The insolubility of the crystals prevented thorough purification of the product, so some error may have been introduced into the characterization tests.

Future goals include purification and upon success elemental analysis. Purification will be attempted by exchanging the bisulfate anion for a tartrate anion. The procedure will also lead into prevented thorough purification of the product, so some error may have been introduced into the characterization tests.

Future goals include purification and upon success elemental analysis. Purification will be attempted by exchanging the bisulfate anion for a tartrate anion. The procedure will also lead into resolution of the two enantiomers of the iron complex. The + tartrate salt diastereomers can be resolved based on their differences in physical properties.

The Plasma Etching of Metals and Metal Compounds

Gordon Shaw
Department of Chemistry and Physics
Skidmore College
Saratoga Springs, NY 12866-1632

Research Advisor: Dr. Judith Halstead

ABSTRACT

Historically, pattern transfer technology in microdevice synthesis (e.g. the manufacturing of integrated circuit chips) has used aqueous (water based) wet etching technology. Increasingly, gas phase plasma dry etching is necessary for the fabrication of the very small features of modern microdevices. With plasma dry etching, like many of the other processes currently used in the semiconductor industry, technology has advanced so rapidly that a clear understanding of the underlying scientific principles have not kept pace for many etching processes. Most kinetic studies in the literature focus on silicon. Etching many metals is also often a critical issue in microdevice synthesis. The current study proposes to investigate the kinetics of the plasma dry etching of titanium and tungsten. The etch rate, halogen and metal atom concentration in the gas phase will be determined as a function of the etch gas pressure and composition.

INTRODUCTION

In recent years, the microcomputer industry has been expanding rapidly. With this expansion has come a staggering wave of advancement in the production of computer chips. The scale on which the circuitry of a cutting-edge microchip must be manufactured is often in the micrometer range (Sze,1988). This clearly requires the use of methods which go beyond direct manipulation of wires by humans or even precision machinery. Plasma etching is just such a method.

In making a computer chip, a thin metal film is deposited on a semiconductor substrate in a process called chemical vapor deposition (CVD,) a chemical reaction outside the scope of this project. The thin film is covered by a non-reactive mask in the shape of a circuit the manufacturer intends to produce. The chip is then subjected to the plasma etching reaction. The process of plasma etching, the chemical reaction being studied in this project, involves the removal of small amounts of metal from a sample reactive gas. The parts of the metal layer not covered by the mask are etched away, and when the mask is removed, the portion of the film covered during etching is left behind as a thin film circuit. These processes are used to deposit layer after layer of metal on a silicon substrate to form the microscale electrical connections necessary for modern microcircuitry.

The plasma etching of titanium and tungsten are of importance to microchip manufacturers. Tungsten is frequently used as a material to form connections between the different areas of the microchips, i.e. in microcircuit interconnects. Titanium is proposed as a diffusion/adhesion barrier if, in the future, copper replaces tungsten as an interconnect material. Copper has an inherent advantage as a microcircuitry material because of its low electrical resistivity. This allows for smaller wire, and hence a more complex, faster circuit. The only drawback is that copper tends to have difficulty adhering to silicon surfaces, and when it does, the metal atoms diffuse into the silicon, making for an unreliable connection. If a layer of titanium is deposited on a silicon surface, and then the copper on top of that, the titanium layer serves the dual purpose of aiding adhesion, and preventing diffusion (Sze, 1988), hence this titanium layer is referred to as a diffusion/adhesion barrier.

Although the etching of these metals is of great importance to industry, the reaction process is not very well understood. It is known that if an electrical discharge is applied to a low pressure gas flow system, a mixture of charged and neutral reactive gas species known as a plasma results. Light emitted from the glowing plasma can be used in emission spectroscopy to determine the concentration of various gaseous species in the plasma. Absorption spectroscopy can also be used to probe plasma chemistry. It is suspected that reactive gaseous species in the plasma combine chemically with the metal sample forming a gaseous metal compound as a product. If light passes through the plasma in a region where these gaseous metal atoms are present, wavelengths of light corresponding to atomic absorption lines will be absorbed, and in situ atomic absorption spectroscopy can then be used to determine the metal atom concentrations. Details of the reaction scheme remain a mystery in the case of tungsten and titanium. The purpose of this project is to develop a kinetic model or reaction mechanism for the plasma etching of titanium and/or tungsten.

EXPERIMENTAL

The apparatus used in this project consists of a Pyrex glass reaction cell, which is kept at a pressure of 0.1 to 0.3 torr by a vacuum pump. The reaction gases used were CF_4, $CFCl_3$, CF_2Cl_2, CHF_3, SF_6, or BCl_3. The gas is flowed through the system at a steady rate regulated by MKS mass flow controllers. With the gas flowing, a current is applied to two parallel plate electrodes inside the reaction cell. The current alternates at a radio frequency (13.6 million cycles per second) and has a power of about 50 watts. This current dissociates the gas molecules into both electrically charged reactive gas species (ions) and electrically neutral gaseous free radicals. This mixture of reactive gaseous species, the plasma, reacts with a bulk metal sample etching a layer of metal atoms off.

In this project, the metal sample (titanium or tungsten foil) is weighed, and then placed on the bottom electrode and allowed to react with the plasma for a determined amount of time. When the sample is removed, it is weighed again. The amount of metal removed per unit time is called the etch rate, and is used as an indicator of the reaction rate of the plasma with the metal.

$$\text{Etch Rate} = \frac{\text{(change in sample mass)}}{\text{(etching time) (sample density) (sample surface area)}} \qquad (1)$$

Emission spectroscopy measurements were taken using a Princeton Applied Research model 1450 photodiode array plasma monitor to determine the concentration of the primary reactive etching species (halogen atoms). The F-atom and Cl-atom concentration were assumed to be proportional to the intensity of emission lines at 755 nm and 728 nm respectively.

Atomic absorption spectroscopy data was obtained by passing light from a titanium hollow cathode lamp through the reaction cell during etching. The 399.8 nm emission from the lamp is absorbed by gas phase Ti-atoms present in the cell. The concentration of these Ti atoms can be determined using Beer's law:

$$\ln (Io / I) = \sigma \, l \, c \qquad (2)$$

where Io is the intensity of the light before absorption, I is the light intensity after absorption occurs in the plasma, σ is the effective cross section which is estimated from electronic transition probabilities to be about $1*10^{-12}$ atoms/cm2 (Halstead et.al. 1990,) l is the length of the light's path in which metal atoms, and hence absorption, will occur (for this project, it is assumed that metal atoms can only exist between the electrodes, so l is the length of the electrodes: 7.5 cm.) C is the concentration of metal atoms in the given region.

RESULTS/DISCUSSION:

In a typical experiment, the etch rate, metal atom and halogen atom concentration were determined as a function of various other system parameters including gas flow rate, type of gas mixture, system pressure, and amount of electrical power.

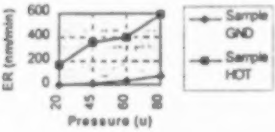

Figure 1: hot and gnd etch rates

As shown in figure 1, etch rates in which the metal sample was in direct contact with the powered (hot) electrode were more than an order of magnitude higher than etch rates during experiments in which the sample was on the grounded electrode. Presumably, the interaction of the charged particles with the metal to is greater when the sample is in contact with the hot electrode since there is electrostatic attraction between gaseous ions and the charge on the electrode. The increased etch rate when this is the case supports the argument for including some kind of interaction with charged gas particles in the plasma etching reaction mechanism. An in depth discussion of the role of ions in the physical removal of metal during plasma etching of silicon is presented by G. Hancock 1994, J.W. Coburn 1994, and W. Yoo, et. al. 1994.

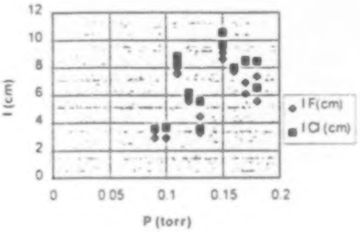

Figure 2: halogen concentration vs. P

Using the emission and absorption spectroscopy techniques described earlier, the fluorine and chlorine atom concentrations in a CFCl3 plasma were measured concurrently with the etch rate and gas phase titanium-atom concentration during an etch. Figure 3 shows that the intensity of both F-atom and Cl-atom emission intensity increases with the pressure of the etch gas (CFCl3.) and hence on the halogen atom concentration in the plasma. There is also a possibility that a double peak in X-emission intensity exists, with one maximum around 0.11 torr, and one around 0.15 torr.

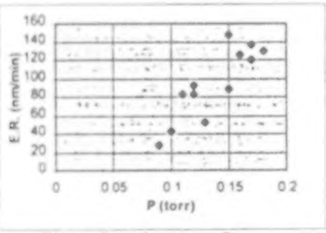

Figure 3: etch rate vs. P

As shown in figure 3, the etch rate also increases with the pressure of CFCl, and exhibits the double maxima around 0.11 and 0.15 torr. This supports the presumption that halogen atoms are the primary initial reactive etching species.

In a previous study of Ti etching with SF6, by Halstead et.al. 1990, it is proposed that F free radicals react at the surface of the metal to produce TiF, which dissociates in the plasma leaving gaseous Ti atoms.

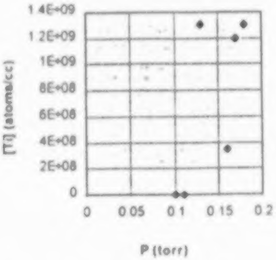

Figure 4: gas phase [Ti] vs. P

Absorption spectroscopy data summarized in figure 4 shows an increase in gas phase Ti atom concentration over the pressure range studied, and once again a double maximum in roughly the same area as the maxima of X-emission and etch rate. This verifies the presence of Ti atoms in the plasma, and solidifies the connection between halogen atom concentration and etch rate.

It is known that varying the oxygen concentration has a significant effect on the concentration of fluorine radicals in the plasma (Kim, et.al. 1995) The results presented in figures 5 and 6 show that oxygen content of the etch gas mixture significantly affects the etch rates of both titanium and tungsten respectively in a CF4 plasma.

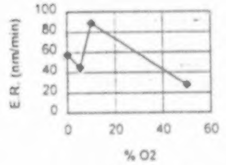

Figure 5: Ti E.R. vs. %O2

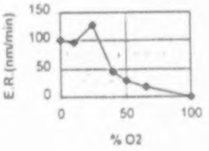

Figure 6: W E.R. vs. % O2

CONCLUSION:

Features of the plasma etching reaction were studied by varying the system's parameters. The fluorine and chlorine atom concentration under various reaction conditions were examined using emission spectroscopy. Absorption spectroscopy was used to determine the concentration of gas phase Ti-atoms in the etching plasma, and support the finding that etch rate increases with halogen atom concentration. It has also been verified that introduction of oxygen into an etching plasma significantly affects the etch rates of both W and Ti. From the data, a kinetic model of the etching mechanism will be constructed. This will provide useful insights into the reaction process of plasma etching. Among them, whether fluorine atoms are enough to account for the etching reaction, or whether some other species are involved.

Pipelines and Potential Disaster
An Introduction to Cathodic Protection

Society's continued dependence on fossil fuels, such as crude oil and natural gas, necessitates that there be a mode for safe, dependable transmission of these fuels The method most often used to move huge quantities of oil and gas is through an extensive system of underground metal pipelines Because these transmission lines are hidden from our view, few of us ever consider the potential danger lurking beneath the surface The natural process of oxidation-reduction (corrosion), over time, will cause metal pipes to fail, resulting in tremendous losses An electrochemical approach, cathodic protection offers a simple, cost-efficient means of insuring pipeline reliability, thus safeguarding human life and our environment

INTRODUCTION

Beneath concrete and asphalt, our pasturelands and waterways, lie a maze of oil and gas transmission lines This network is so vast in its scope, encompassing large sections of the land and water we depend on for our continued subsistence, that we cannot afford to behave irresponsibly in its maintenance

Of primary importance in the effort to maintain safe, reliable transmission lines, is the necessity of dealing with the perpetual threat of corrosion and eventual degradation of those metal lines Cathodic protection has been the method used most often to protect metal in buried fuel tanks and pipelines, employing the basic concept of a galvanic cell, with a cathode and anode [1] Simple in approach, cathodic protection halts the natural process of metal to metal ion loss from pipe to its surrounding electrolyte through installation of one of two types of systems galvanic or impressed current [2] Either of these systems produce sufficient levels of protective current that serve to polarize the cathodic area (pipeline) in relation to the anodic area (the galvanic or impressed systems) establishing an equilibrium, thus preventing further flow of ions from the metal into solution [3]

Oxidation-Reduction Reactions

The chemical reaction responsible for corrosion of metals is referred to as an oxidation--reduction reaction, or redox reaction[4] which describes the chemical process of corrosion of metal pipelines Prior to installation of a cathodic protection system, a pipeline will contain corrosion cells, with each cell containing a cathode and an anode Left unprotected, metal ions are lost (oxidation) at the anodic areas, with acceptance of electrons (reduction) occurring at the cathodic areas (See equations 1-3)

Half-reaction at the anode $2Fe \dashrightarrow 2Fe^{2+} + 4e^{-}$ (oxidation) (1)
iron ------> dissolved iron ions + electrons

Half-reaction at the cathode $O_2 + 2H_2O + 4e^{-} \dashrightarrow 4OH^{-}$ (reduction) (2)
dissolved oxygen + water + electrons ------> hydroxide ions

Total reaction $2Fe + O_2 + 2H_2O \dashrightarrow 2Fe^{2+} + 4OH^-$ (3)
iron + dissolved oxygen + water ------> dissolved iron ions + hydroxide ions

Once cathodic protection is implemented, contrasting application may be made with oxidation taking place at the anode(s) of the system and reduction occurring at the pipeline [5]

Galvanic System

The galvanic (sacrificial) system of cathodic protection is usually applied when required levels of current needed for pipeline protection and electrolyte (soil or water) resistivity is low [6] Adequate protection is achieved by utilizing a metal more reactive to oxidation than the metal to be protected as the sacrificial anode, and connecting it to the pipeline by a wire Because the sacrificial metal is a better reducing agent (more easily oxidized) than the iron pipe, needed electrons are supplied from the anode, flowing through the wire to the pipe, preventing oxidation of the pipe and further loss of metal [7] (See figure 1)

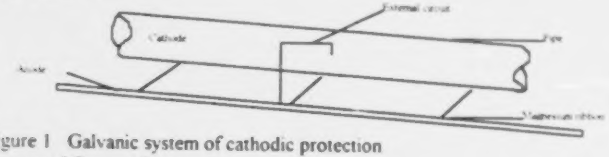

Figure 1 Galvanic system of cathodic protection

Impressed Current System

Impressed current systems are employed when current requirements and resistivity of the electrolyte are high, necessitating that dc voltage levels be adjusted to fit specific conditions Adequate levels of protection are achieved through installation of a transformer rectifier control unit and several anodes These anodes, placed in the electrolyte and joined to the positive terminal of the rectifier with a wire, provide a flow of electrons that pass through the rectifier, out its negative terminal, and on through another wire to the metal pipe [8] (See figure 2)

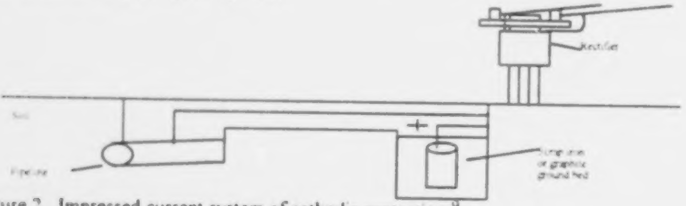

Figure 2 Impressed current system of cathodic protection [9]

Brief History of Cathodic Protection

The concept of protecting metal from ion loss is not a new one As early as 1823, Sir Humphrey Davy was commissioned by the British Admiralty to examine the corrosion of the copper sheathing on their naval vessels By 1824, Davy reported that the loss of copper could be decreased by using sacrificial blocks of iron coupled to the hulls of the ships, effectively halting further ion loss into the surrounding salt water [10] So efficient was this method that marine growth (formerly poisoned by copper ions going into solution) multiplied upon the hulls of British vessels and reduced their speed, prompting the Admiralty to decide against it After Davy's death in 1829, his cousin, Edmund Davy, employed methods of localized protection of iron buoys with zinc anodes Yet, overall cathodic protection of marine vessels was not examined again until about 1950, this time by the Canadian Navy With the use of antifouling paints in combination with anticorrosion paints, it has been proven that it is possible to cathodically protect ships and considerably lessen maintenance costs [11]

With the availability of AC current, impressed cathodic protection systems of metal underground structures took place in England and in the United States, about 1911 By the 1930's, most, if not all of the major pipeline companies were, to some degree, using cathodic protection and coatings to protect their pipelines from corrosion [12]

Cost of Corrosion

The cost of metallic corrosion extends far beyond the estimated $300 billion spent in the United States each year on both direct and indirect losses, which include shutdowns, loss of product, loss of efficiency, contamination, and over-design. Gas pipeline incidents, at a high of about 400 in 1970 and a low of around 60 in 1989, each resulting in serious injury and fatalities to humans, as well as damage to the environment, are losses that cannot be measured in dollars and cents.[13] Corrosion and Cathodic Protection engineers, working with N.A.C.E. (National Association of Corrosion Engineers), the petroleum industry, and the U.S. Department of Transportation, have contributed immensely to the current decreases in pipeline failures within the United States.[14]

CASE HISTORIES OF PIPELINE DISASTERS

Technical descriptions of corrosion and cathodic protection, though informative, are inadequate in depicting the reality of what occurs when high-pressure oil and gas transmission lines are not consistently maintained. The December 9, 1987 issue of the Tulsa World reports that the Williams Pipe Line Company had been fined $209,000 for violations of federal pipeline safety regulations between 1983 and 1985. This fine, the maximum amount permitted by law, was a result of a federal investigation that began after a Williams pipeline, in Mounds View, Minnesota, exploded in July of 1986, injuring one person and killing a woman and her daughter. Two hundred thousand dollars of the total fine was penalty for failure of the pipeline company to maintain adequate cathodic protection on several sections of pipeline. A National Transportation Safety Board report on the explosion stated that the rupture was due to "failure of the Williams Pipe Line Company to correct known deficiencies in the cathodic protection applied to the lines."[15]

Although ruptures of pipelines due to corrosion account for about 12.4% of reportable incidents between 1970 and 1993, this percentage represents a way to simply and significantly lower the likelihood of similar incidents in the future and is, in fact, now taking place. U.S. Gas Pipeline Safety Records indicate that injuries from gas incidents have steadily declined, despite the fact that there over 1.6 million miles of regulated pipelines spread out over this country. With the combined efforts of oil companies, whose standards often exceed those imposed by the U.S. Department of Transportation, it is conceivable that corrosion-related incidents in oil and gas transmission lines will continue to decrease in the coming years.[16] Yet, this expected decrease does not permit us to lessen our vigilance in this area. A "worst-case scenario" of what can happen to us here, in the U.S., is taking place in Russia, right now.

The February 1996 issue of Discover reports that for the past 20 years, oil has been pumped through the Kharyaga-Usinsk regional pipeline, stretching across 100 miles of northern Russia into its heartland, with little regard for the environment. Carrying as much as 220,000 barrels of oil each day, the World Bank estimates that since 1994, close to 730,000 barrels--more than 100,000 tons of oil--have seeped out of miles of corroded pipeline into the surrounding water, land, and air. A U.S. government report estimates the amount of oil leaked as closer to 270,000 tons. Either way, if we accept the 100,000 ton estimate in favor of the higher one, this spill surpasses that of the Exxon Valdez nearly three times over. Initially, huge ponds of oil, standing six to seven feet deep and 20 to 30 feet across, covered an area of approximately two to three miles. Today, most of the wildlife have gone and studies indicate that the freshwater fish catch in the region has plummeted by about 85%. This incident's far-reaching consequences in irreparable damage to Russia's Earth capital, with loss of biodiversity to the surrounding ecosystems render the economic expense of massive clean-up efforts to be negligible in comparison. Yet, all over Russia, old and corroded pipelines continue to carry tons of oil in an attempt to support a teetering national economy.[17]

FIELD HISTORY

Cathodic protection may be measured by using an electrode which has a relatively fixed value of potential (or electromotive force in volts), regardless of the environment in which it is used, called a reference half-cell or reference electrode.[18] For our purposes, the Saturated Copper-Copper Sulfate Half-Cell was the electrode chosen. This electrode consists of metallic copper immersed in saturated copper sulfate. It is most often used in taking field measurements and adequate for most corrosion investigations.[19]

The designated site for testing was a 30" line, currently being operated by Arco (Seaway) Several feet away from the Seaway line and parallel with it, are the test leads for a pipeline operated by Aquila, so it was tested for cathodic protection, as well Testing began at the Seaway mile marker #96 + 0500 ft , off of FM 362, and ended at Seaway's mile marker #98 + 3310 ft , at Reids Prairie Road

Potentials were taken by placing the tip of the electrode into the soil (electrolyte) over the pipeline near one of its test leads The positive (red) wire from the voltmeter was connected to that test lead, while the negative (black) wire was connected to the copper-copper sulfate half-cell Using the 2-volt DC scale, readings registered upon the face of the voltmeter (a Beckman HD-110 digital multimeter) and were subsequently recorded Results are recorded on table 1

Table 1 Results of potentials taken with copper-copper sulfate electrode

Mile Marker	Location	Seaway	Aquila
#96 + 0500 ft	S S FM #362	- 0 608V	- 1 455V
#96 + 4210 ft	S S Howell Rd	- 0 615V	- 1 469V
#98 + 3310 ft	Reids Prairie Rd	- 0 503V	- 1 438V

Potentials registering more negative than - 0 850V indicate that cathodic protection is in place and operating The potentials taken on the Seaway line showed that it was not cathodically protected, while the Aquila line was A call to Kyle Coslow of Arco revealed that the 30" Seaway line and its facilities were being changed in order to accommodate transmission of oil instead of gas, necessitating that the cathodic protection system be turned off until construction on the line could be completed

CONCLUSION

As the demand for fossil fuels grows, the network of underground oil and gas transmission lines expands with it Advanced methods of corrosion prevention and cathodic protection are now routinely applied to these new lines Yet, interspersed throughout the country are their aging predecessors, many of which have been in operation for more than forty years Originally placed beneath uninhabited sections of land, these pipelines now lie beneath large residential and commercial areas where it would be impractical and/or impossible to replace them with newer pipe Properly applied, galvanic and impressed current systems of cathodic protection continue to be the preferred approach for preventing pipeline failures

During the course of my research, several pipelines were examined Of this number only one (Seaway) was found to be without cathodic protection This discovery highlights the fact that although most oil and gas transmission lines are never seen, they must not be forgotten Failure to properly protect these lines, whether it be due to corporate down-sizing, ignorance, and/or gross negligence, will eventually result in catastrophic consequences This is something none of us can afford

ACKNOWLEDGMENTS

I would like to thank Dr Brian Hale, Dr Verne Lehmberg, and the people of N A C E (National Association of Corrosion Engineers) for their guidance and support Special thanks to my father, Jerry C Cochran, without whose help I would never have attempted to research a subject such as cathodic protection

Monitoring water quality and quantity is necessary in order to effectively manage land use decisions upstream. It is also needed to plan flood control structures and estimate the dependability of water supplies. This project was conducted on the Rum River in Anoka, MN. The purpose was to monitor the River for one sampling season and determine the quality and quantity of the water body, and also compile much needed baseline data on the river. The study revealed that the Rum River has acceptable water quality.

BACKGROUND

The Metropolitan Council Environmental Services (MC) is required by state legislature to determine target loads for every watershed in the Twin Cities Metropolitan Area. The MC developed a program which issues grants to local governmental agencies in order to collect water quality baseline data. The MC purchases the water sampling equipment and analyzes the water samples for the local agencies. The MC believes this program will get local governmental units involved in keeping water quality a top priority and increase their desire to educate the people living in each watershed and contributing to the water quality. The Anoka Conservation District (ACD) was one of the governmental agencies to receive a grant from the MC. The ACD tests the Rum River outlet to the Mississippi River in Anoka, Minnesota.

The Rum River starts at Vineland Bay of Mille Lacs Lake, threads together several lakes near the city of Onamia, then makes its way along a 148 mile course to the city of Anoka and the Mississippi River (Homuth, 1977). The river flows through three major cities: Anover, Ramsey and Anoka, where it empties into the Mississippi River. Along this course it travels through forested areas, agriculture farmland, cities and industrial developments. Monitoring of the Rum River is necessary in order to effectively manage land use decisions upstream. It is also needed to plan flood control structures, and estimate the dependability of water supplies (Brooks, et al, 1991). The overall objectives of this research project are to: (1) compare water quality results of the Rum River to standards determined by the Pollution Control Agency and the Environmental Protection Agency and (2) establish a streamflow-elevation rating curve so water quality values can be related to streamflow discharge.

MATERIALS AND METHODS

Sampling equipment (ISCO 6700) which collects streamwater was set up near the outlet of the Rum River. The location was chosen based on accessibility, safety from vandalism or accidents with boats and canoes, ability to take measurements of the river, and stormwater outlet locations. The sampling equipment included a 24 unit water sampler, a staff gauge, and a shelter box which stores the water sampler under lock and key. The water sampler was triggered when the river level reached a certain elevation. It collected water samples every three hours during a stormflow event. Samples were then weighed based on elevation and combined together. The MC tested the samples for the following water quality parameters: Total Suspended Solids (TSS), Volatile Suspended Solids (VSS), Total Phosphorous (TP), Dissolved Phosphorous (DP), and Chemical Oxygen Demand (COD). The MC chose these parameters because they were determined to give the best measure of water quality with the least amount of testing.

Discharge was measured at relatively the same time water samples were collected and at approximately the same location of the water sampler. It was determined by:

$Q=V*A$ (1)

where:

Q=Discharge (ft^3/s)

V=Velocity (ft/s)

A=Area (ft^2)

The cross sectional area of the stream was determined by wading across the river with a rope marked at 10 foot increments. Every ten feet the depth of the River was measured with a ruler and the velocity was measured with a Pygmy flow meter at .6 meters from the surface. Elevation was determined by taking a staff gauge reading at the same time discharge was measured. Once all data was collected for the season, it was used to develop a streamflow-elevation rating curve. The rating curve is shown in figure 1, it is convenient because it allows the ACD to look at previous data and approximate how much water will be discharging from the river given a certain elevation. With this data the ACD can determine if any flooding precautions need to be made.

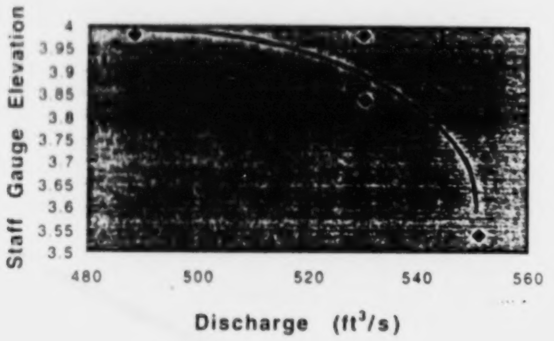

Figure 1: Rating curve, relates elevation to streamflow discharge

RESULTS AND DISCUSSION

The results of the water quality parameter tests remained fairly consistent. Table 1 indicates the results. The average level of each parameter tested for the sampling season was below acceptable water quality parameter guidelines for in-stream nonpoint source pollution. These guidelines were based on Minnesota Pollution Control Agency criteria and the Environmental Protection Agency standards. These results verify that the Rum River has acceptable water quality. One thing should be considered when reading the water quality test results; the composites made for each stormflow event were based on elevation and not

BEST COPY AVAILABLE

discharge. That could have caused the results to be off because it was not taking into account how much water was actually discharging for that particular stormflow event. For example, a larger river may rise the same amount throughout a storm event as a smaller one, but because the cross-sectional area is larger there is more discharge (Brooks, et al, 1991).

The results of the streamflow-elevation rating curve were not accurate (Figure 1). In theory, as the elevation of the river rises, so should the discharge. This discrepancy was most likely due to limited data and also imprecise data collection. The staff gauge was difficult to read at times and could have been tampered with. Also, the Rum River was approximately 200 feet wide at the site where data was collected, so some error was likely to occur when measuring the cross sectional area. Each time it was difficult to follow the same path when crossing the river and keep that path straight. Also a rope was used to determine depth from shore. Due to the inaccuracies in the rating curve there is a lack of reasonable correlation between water quality parameters and streamflow discharge.

Table 1: Water quality test results

	Period of Sampling					
Parameters (mg/L)	9/7/14	9/21/25	10/17/21	10/22/24	10/24/31	Acceptable Levels
COD	31	17	20	35	30	50
TP	0.06	0.07	0.09	0.06	0.06	0.1
DP	0.04	0.06	0.05	0.03	0.02	-
% Dissolved	67%	86%	56%	50%	33%	20-80%
TSS	6	4	3	4	5	30
VSS	2	2	2	2	<2	-
% Volatile	33%	50%	67%	50%	40%	50%

Peak Discharge (ft^3/s)	542	560	553	541	470	-

CONCLUSION

Many of the procedures used for monitoring in this project were not the most accurate. However, given funding, time constraints, and degree of accuracy required, they were satisfactory. The results of this project will allow the ACD to improve upon future monitoring programs.

Changes, are already underway. A dam downstream of the Mississippi River (Coon Rapids Dam) was down during this project so water levels of the Mississippi and Rum were low, making it easy to wade across and measure the cross sectional area and velocity. Next season the Dam will be up again, which will cause the water levels in the Mississippi and Rum to rise and no longer be shallow enough to wade across. The Dam will also cause the Mississippi to back water into the Rum and effect water quality results. The ACD, with advise from the MC decided to move the location of the water sampler for next season. The new location of the sampler will be upstream of this summers site and below the Anoka Dam. At this site a rating curve of the river was already determined by engineers and a continuous monitor will be set up to take elevation readings every half hour. Results for next season will be much more accurate.

Lead Contamination of Canned Food Products from Argentina

Margaret M. Ryan

Environmental Studies Program
University of North Carolina at Asheville
One University Heights
Asheville, NC 28804-3299

Faculty Advisor:
Dr. Richard P. Maas

The Argentinean food industry uses lead-alloy solders to seal cans containing food products, posing a serious problem of lead contamination in the food. Lead levels greater than 10 ug/day, if ingested, are considered toxic to humans and can lead to measurable neurological damage. The type of food (e.g., acidic, in oil,) contained in the can plays an important role in how much lead is being leached from the solder. This study analyzes 586 food samples of four different food types and 583 can samples by Atomic Absorption Spectrophotometry to determine the lead concentration of the food and to see if there is any lead remaining in the solder of the cans. The USFDA standard for lead in canned food is 0.250 ug/g. The results of this study indicate that 72% of the Argentinean food sample groups have at least one sample with lead levels that exceed the USFDA's standard. It is also found that tomato based products and fish in oil exceed the standards by the widest margin. Additional areas of interest within this discussion may include, the importance of keeping the laboratory equipment and environment free from lead that could possibly contaminate the analysis.

INTRODUCTION

Lead is a toxic substance that has been harmful to human health since ancient history and has become increasingly evident since the beginning of the Industrial Revolution. The implications of lead on the human body are particularly severe with children and pregnant women. It is known to affect cognitive behavior and learning development in children as well as cause miscarriages, premature delivery, and stillbirths in pregnant women[1]. There are many other serious health problems associated with lead that begin showing signs at lead levels as little as 10.0 ug/day. This hazard can be prevented with the elimination of lead from our environment. With the increased awareness of the implications from lead, great strides are being made to eliminate lead from our daily intake. There is considerable interest and concern in the amount of lead intake from paint, dust, soil, water and food. Lead in any of these may come into direct contact with a person through their daily activities. Removal of the source and restriction of further use is necessary as preventive medicine.

Lead enters the human body primarily by way of inhalation or ingestion. The major source of ingested lead is from the food we eat. The food may possibly be contaminated by a number of different sources which include:

-Biological uptake of lead from soils into plants consumed by man. Root vegetables contribute more lead than surface vegetables.

-Contact with industrial machinery and greases during harvesting and processing.

-Manufacturing and storage in cans.

-Location where vegetables are grown in relation to major highways. Airborne lead from automobile emissions accumulates on the vegetation. An inverse relationship between distance from the road and lead content has been observed. Although, in the United States, the problem of lead contamination from automotive sources has been reduced over the years by banning of leaded gasoline, in many other parts of the world, including Argentina, leaded fuels are still being used.

-The addition of lead in the kitchen. For example, the lead-containing glazes in pottery used to contain food or the tap water used in cooking.[2,3]

The interest of this research is the extent of lead contamination of food from the lead-alloy solder used in the manufacturing of cans by the Argentinean food industry. The cans are assembled in such a way that the contents of the can are exposed to the available lead along the seam of the wall. Further contamination results from the splashing of molten solder used in the manufacturing process.[4] The United States has taken great measures to reduce the daily lead intake by eliminating lead in the solder used to seal cans. Argentina, however, is in the process of elimination and considerable amounts of lead are still being detected.

The sample must proceed through a series of preparations to ensure the most representative sample. Initially, the food sample is blended for complete homogeneity. The food settled closest to the seam of the can typically contains the highest concentration of lead, so blending the entire contents is necessary to ensure thorough mixing. Next, the sample must sit through 16 hour nitric acid predigestion in order to break up all lead particulates. Lastly, the nitric acid/peroxide digestion process is performed to solubilize the metal and to remove any organic matter.[5] The sample is then ready for analysis.

The theory behind Atomic Absorption Spectrophotometry involves atoms in their ground state energy level being excited to higher energy levels by absorption of particular wavelengths of radiation. A hollow cathode tube made up of the element of interest, in this case Pb, emits wavelengths of radiation at which the elemental atoms absorb. The sample is converted to atomic vapor by aspirating it into a flame or graphite furnace which lies in the path of the radiation source. The larger the population of ground state atoms the greater the absorption of light. The absorption signal is used quantitatively in that the absorption is proportional to the concentration.

METHOD

Apparatus and Reagents

a) Atomic absorption spectrophotometer - Thermo Jarrell Ash Smith-Hieftje 11 with furnace atomizer 188 was used for all food samples. Single beam. Automatic background corrector with Deuterium background. 283.3 nm wavelength. 1.0 nm bandwidth.
Thermo Jarrell Ash Smith-Hieftje 12 with a long path air/acetylene burner was used for all can samples. Smith-Heiftje background. 217.0 nm wavelength. 1.0 nm bandwidth.
b) Food Processors - Black and Decker Power Pro FP 1000 and Black and Decker HC 2000
c) Ammonium dihydrogen phosphate -Dissolve 5.00 g in 0.3%(v/v) nitric acid and dilute to a volume of 1L.
d) Nitric acid - 2%. Dilute 10.0 ml concentrated HNO_3 to 500.0 ml
e) Lead Standard - NBS Standard Reference Material, 1566a Oyster Tissue 0.371%Pb

Sample Preparation

The tops of each can are washed with soap and water, rinsed three times with lead-free tap water and three times with deionized water. The top is removed and the contents of the can are transferred to a clean food processor. The food is blended for 3-5 minutes to ensure complete sample homogeneity.

25.0 g of blended food is weighted into a clean, labeled, weighed 250 ml polyethylene sample bottle and recorded to the nearest 0.01 g. Approximately 25.0 ml of 50% HNO_3 is added, shaken and allowed to stand for 16 hours to break up any particulate lead present. After the predigestion, the bottle with sample is weighed to determine the exact weight of the 50% HNO_3 used.

Approximately 1.0 g (weighed to the nearest 0.0001 g) of the food/nitric acid mixture is weighted into a tared, clean, labeled 50.0 ml Pyrex beaker and covered with a watch glass. For every ten food samples a duplicate of one food sample, a digestion blank, a spiked sample and a reference sample are prepared. The digestion blank is prepared by treating 360 ml of deionized water using the same procedures as a canned food sample. The spiked sample is prepared by adding 200.0 ul of 1.00 ppm lead reference solution to a one gram food sample. The reference standard is prepared by weighing 0.25 - 0.60 g (weighed to the nearest 0.0001 g) of a National Institute of Standards and Technology into a tared 50 ml beaker, dissolving in 20.0 ml of 50% HNO_3 and evaporating on a hot plate to approximately 5.0 ml.

To each food, duplicate, blank, spike and reference sample, 6.0 ml of concentrated HNO_3 and 2.0 ml of 30% H_2O_2 are added then placed on a hotplate and heated slowly to near dryness. This procedure is repeated twice using 3.0 ml HNO_3 and 1.0 ml H_2O_2 each time allowing it to reach complete dryness on the final step. If charring should occur, repeat last procedure.

Remove samples from hotplate and allow to cool. Rinse watch glasses into the beaker with 1.0 - 3.0 ml of 2% HNO_3. The solution is next gravity filtered through Whatman 43 or 54 filter papers into 10.0 ml volumetric flasks being sure to rinse the sides of the beakers with 2% HNO_3. The filter paper is removed and the funnel is rinsed. Fill to volume with 2% HNO_3. The samples are transferred to labeled 50.0 ml polypropylene vials and are ready for analysis.

The can samples are prepared by washing the cans thoroughly to remove all food, rinsed five times with lead free tap water and three times with deionized water. The cans are filled with 5%(v/v) acetic acid and allowed to sit 24 hours before analysis.

Instrument Analysis

EPA method 239.2 is used to analyze all food samples with the modifications of all samples being prepared in 2% HNO_3 and the addition of 20%(v/v) of ammonium dihydrogen phosphate just prior to each sample analysis.

A calibration curve to analyze the food samples is installed using a series of lead standard solutions of 0.0, 5.0, 10.0, 20.0, 30.0, and 50.0 ppb Pb in 2%HNO_3. The acceptable line correlation being greater than 0.995 and quality control standards of 2.0, 15.0 and 40.0 ppm having absorbencies within ±10%. The samples are analyzed for absorbance. After every ten samples the instrument is calibrated with a control and duplicate sample run having absorbencies within ±10%.

To install the calibration curve to analyze the can samples a series of lead standards solutions of 0.0, 0.1, 0.3, 0.5, 1.0 and 2.0 ppm Pb in 5% HOAc are used with an acceptable line correlation being greater than 0.995 and quality control standards of 0.2, 0.6, 1.5 ppm Pb having absorbencies within ±10%. After every ten samples a calibration with a control and duplicate sample run having absorbencies within ±10% is performed.

The amount of lead in the food is calculated as follows

$$\text{Pb Concentration (ug/g)} = \frac{\text{(AA signal ug/l)(0.0100 l)(Dilution Factor)}}{\text{(Mass of Analytical Food Sample g)}} \qquad (1)$$

where

$$\text{Dilution Factor} = \frac{\text{(Mass of gross food sample + mass of 50\% } HNO_3\text{)}}{\text{(Mass of gross food sample)}} \qquad (2)$$

RESULTS AND DISCUSSION

Table1 Statistical Analysis of Lead in Food and Can Extract Categorized by Food Type

Food				Lead Extracted from Can	
Food Type	n	Mean Lead (ug/g)	%>FDA Standard	n	Mean Lead in Can (ug/l)
Fish with no Oil or Tomato Sauce	57	0.453	28.1%	57	583
Fish in Oil	121	0.580	52.9%	121	506
Tomatoes or Product in Tomatoes	300	1.333	60.7%	298	931
Other	108	0.705	48.1%	107	385

The results indicate that 72% of the Argentinean food sample groups have at least one sample with lead levels greater than 0.250 ug/g. Table 1 gives a breakdown of lead levels according to food type. It can be seen that all food types have lead levels that exceed the USFDA standard with the highest concentrations of lead found in the tomato based products giving evidence that the chemical properties of the food play an important role in the amount of lead being leached from the solder. It is also found that there is a considerable amount of lead still available to be leached from the solder. A correlation between the amount of lead in food and the amount of lead remaining in the solder was considered but found to be difficult with the reasoning that the initial concentrations of lead in the solder are unknown and that the food may have already been contaminated by the sources mentioned previously.

Table 2 categorizes lead concentrations by brand name. It can be seen that all but 1 of the 19 brand name groups have percentages of lead in food that exceed the USFDA standard with the brand names Arcor, Margarita and Santa Isabella having the highest exceedences. It can also be seen that Arcor and Santa Isabella have the highest concentrations of lead still remaining in the can. This is an indication that the solder is the primary source of contamination in the food.

Table 2. Statistical Analysis of Lead In Food verses Can by Brand Name Category

	Food			Lead Extracted From Can	
Brand Name	n	Mean Lead (ug/g)	% Food> USFDA Standard	n	Mean Lead in Cans (ug/l)
Alco	55	1.177	61.8%	55	776
Arcor	20	6.866	100%	20	2156
Canale	53	0.589	58.5%	52	681

Mellino	60	0.815	58.3%	60	476
Parmalat	20	0.324	45.0%	20	1171
Puglisi	30	0.266	20.0%	30	503
Rural	20	0.550	25.0%	20	313
Santa Isabella	20	1.993	75.0%	20	1286
Silvia	35	0.821	48.6%	35	734
Supremicia	42	0.536	66.7%	42	504
Versalles	43	0.748	58.1%	43	186

A problem encountered throughout the analysis was obtaining zero concentrations of lead in the blank reagents. Before estimating the lead concentrations of the samples a mean concentration of the blanks is subtracted from all samples to adjust for non-zero blanks.

The blank, duplicate, spiked and standard samples undergo the same digestive procedures as the food samples in order to expose all the samples to the same conditions. If a situation occurs where theoretical values are not observed within certain percentages then measures must be taken to find and fix the problem.

Analysis was done on equipment and reagents used throughout the experiment to determine at which point the blank was being contaminated. Starting at the beginning of the experiment and in a step-by-step manner, samples from squirt bottles, pipets, polyethylene bottles, etc., were obtained and analyzed. It was found that the major source of contamination occurred from the Pyrex glass beakers and watch glasses employed during the hotplate digestion procedure. A certification process was then installed involving daily analysis of samples obtained from laboratory equipment that was thoroughly cleaned and run through an acid digestion procedure before the equipment was to be used in the actual digestion of the food samples.

It was later found that switching to Teflon beakers greatly reduced the lead contamination of the blank. An other observation that may be considered an advantage in using Teflon is in the handling beakers. It was found that the Teflon beakers can be removed from the hotplate using one's hands as opposed to tongs. Emphasis must be made here in that this is not a recommendation but an observation. Disadvantages in using Teflon are that the digestive procedure appears to take longer and the beakers are transparent prohibiting the visual progress of the digesting sample. The reduction of lead contamination by using Teflon was possibly the most important finding of this research and should be stressed upon at the beginning of any further experimental procedures involving lead analysis.

ABSTRACT

An Isologger is a lightweight personal toxic gas monitoring device recommended and used by industrial hygienists and product safety employees interested in workplace safety. If toxic gases are present in an environment, Isologgers warn the user of potential danger by sounding an alarm and recording the concentration of the gas. An experimental method used in the calibration of five of these devices subjected them to varying concentrations of the toxic gas, toluene diisocyanate (TDI), at different humidities. Because of the great risk to human health, it is important that these devices function properly at all times. Unfortunately, under extreme humidity conditions, these devices fail to indicate potentially dangerous levels of toxic gases. It was concluded that a lapse in quality control had occurred at the manufacturing facility, which could have severely affected the health of the exposed workers.

INTRODUCTION

Over the past 30 years, steady improvements and refinements have been made in the understanding and application of environmental sampling and analysis. One important application is the sampling of the workplace environment to protect the health of workers. Toluene diisocyanate (TDI) is a workplace pollutant associated with the production of polyurethane foams, elastomers, and nylons. Newer sampling and analytical procedures have been developed to achieve lower limits of detection for TDI due to lowering of exposure limits and eliminating some inherent problems with the older methods. Some other purposes for airborne sampling of isocyanates include assessment of worker exposure, compliance with exposure limits, assessment of ambient air quality, toxicological studies, and evaluation of monitoring methods and instruments. Innovative technology has advanced the field of isocyanate sampling. At the present time, paper-tape monitors are the most popular instruments available for monitoring for TDI. These are personal devices which can be worn at the workplace, as seen in Figure 1. The purpose of this study was to determine the reliability of paper-tape toxic gas monitoring devices in detecting levels of TDI at extremes in relative humidity in order to ensure user protection.

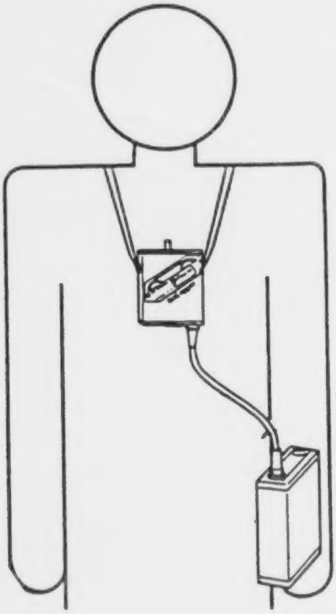

Figure 1. Isologger system on a person (MDA Scientific 1994).

MDA ISOLOGGERS

In April 1995, Bayer Corporation Product Safety Department in Pittsburgh, Pennsylvania, purchased five Isologger devices from MDA Scientific. An Isologger is a lightweight, personal toxic gas paper-tape monitoring device recommended and used by industrial hygienists and product safety employees interested in workplace safety. A master illustration of the Isologger systems is shown in Figure 2. Calibration of these toxic gas monitoring devices is essential in industrial settings where harmful gases often result as a product of manufacturing. If toxic gases are present in an environment, Isologgers record the concentration of the gas. Isologgers, as paper-tape monitors, indicate toxic gas exposure based on the collection of isocyanates on chemically impregnated filter paper tapes. The isocyanate reacts with the chemicals on the tape to produce a characteristic color stain. The intensity of the color stain, which is proportional to the concentration of isocyanates in the air, is measured photochemically and displayed directly on the tape. Inside the Isologgers is a white chemically coated tape called a Chemcassette. Chemcassettes indicate the level of toxic gases present in the environment by inscribing a discoloration on the tape. The Isologger monitors run on a rechargeable battery which can sample continuously for about 10 hours. At the end of a sampling session, the electronically stored data can be retrieved via a personal computer. Built-in alarm systems warn the user of potentially dangerous exposures. Because of the great risk toxic gases pose to human health, it is important that these devices function properly at all times.

THE EFFECTS OF TOLUENE DIISOCYANATE (TDI)

TDI is created in the production of many pharmaceutical products and is dangerous to employees exposed to the toxic gas. Some of the acute harmful effects of exposure to TDI are: dryness of the throat, tight feeling in the chest, itchy and red eyes, headache, nausea, fatigue and loss of appetite. Chronic exposure to the gas causes neurotoxic damage, including permanent brain and nervous system damage, loss of memory, and liver and kidney damage (Bayer Corporation 1992). Because of these severe human health effects, it is essential that significant precaution is taken when handling TDI. Calibration techniques are necessary in order to ensure their reliability. However, an inherent problem with the devices is that operation in harsh environments tends to cause false readings, subsequently not warning the user of potentially dangerous levels of toxic gases.

CALIBRATION METHOD

The experimental method used in this research involved subjecting the Isologgers to varying concentrations of TDI at different relative humidities to assess their reliability in extreme, but realistic environments. Atmospheres containing TDI at various concentrations and relative humidities were generated in the Bayer Industrial Hygiene Lab using a diffusion technique (three 2-mL volumetric flasks served as the diffusion cells). The TDI concentrations were obtained by controlling the temperature of the diffusion cells (51.5 C• for ~9 ppb (parts per billion), 59.5 C• for ~15.6 ppb, and 75 C• for ~44.6 ppb of TDI). The desired relative humidity of the atmosphere was obtained by controlling the humidity of the diluent air using a Miller-Nelson-Flow-Temperature-Humidity Control System (Model HCS-401).

The TDI atmosphere was measured concurrently with the five Isologgers and two 13-mm diameter 1-(2-pyridyl) piperazine (PP) coated filters as controls. The results of the Isologgers and the two control filters were then compared using a High Performance Liquid Chromatograph (HPLC). By comparing the 13-mm PP filters to the Isologger readings, conclusions were made about the validity of the five Isologgers.

Daily configuration and data retrieval of Isologgers was accomplished via a personal computer software program called *Isologger*. When employees use this program in an ordinary working situation, a profile with a graph of their results can be obtained and the data stored for future reference. During this experiment, each Isologger was subjected to a daily configuration in this program before a test could be run. Utilizing this software greatly facilitated the graphing and summarizing of test results.

RESULTS

In conducting the calibration of these devices, it was discovered that at certain humidities and concentrations of the gas, the devices were reading falsely. The calibration procedure revealed that the devices were consistently underestimating the TDI concentrations at various humidities and concentrations tested. At 50% relative humidity (RH), the Isologgers read the TDI concentration correctly. However, at lower humidities (25%RH), the tape monitors were ~30% lower, and at higher humidities (75%RH), the monitor responses read ~20% higher than the true concentration. A graph of the results represented in Figure 3, which portrays the deviancy of the monitoring systems from the ideal. The devices are designed to give a concentration measurement every two minutes. At higher humidities (75%RH and higher), consecutive two-minute readings oscillate around the true mean reading. These oscillations are due to the tape becoming slightly more transparent as water is absorbed. The oscillations can be very dramatic and the user must be made aware of this effect. Compared with the reference method, the Isologgers underestimated TDI concentrations at extreme measurements of relative humidity. Many of the Isologger readings fell below the ideal region, shaded in Figure 3, underestimating the concentrations of TDI.

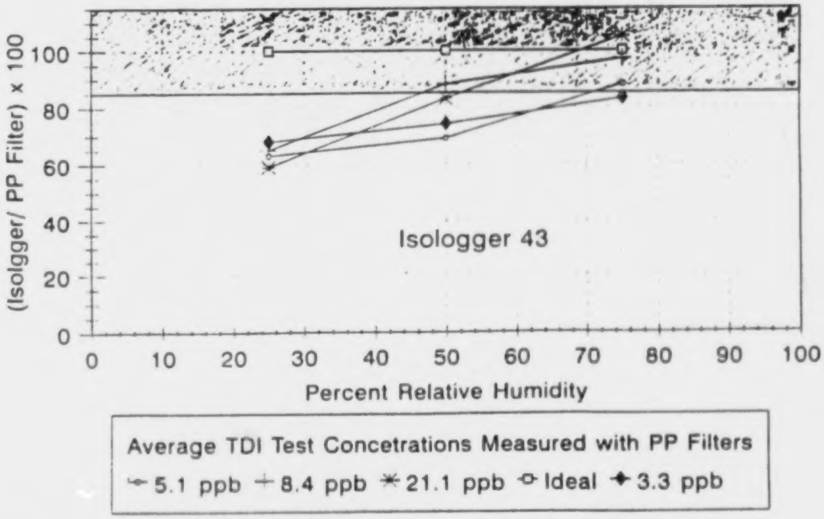

Figure 3. Percent relative humidity readings of one Isologger subjected to varying concentrations of TDI and then compared to the ideal (Dharmarajan 1996)

Further experiments revealed that the Chemcassette tapes for the Isologgers were coated with a partially-degraded chemical which deteriorated even further during transport in the hot summer months during the calibration period. A quality control problem had taken place at the manufacturer's and could have severely affected the health of the users of these devices. Those individuals involved in preparing the Chemcassettes had not properly checked the chemicals, allowing degraded substances to be used on the tapes. Based on these findings, until the quality control problem could be ameliorated, the paper-tape Isologger monitors were used only as screening instruments for TDI, and not for government exposure compliance purposes.

CONCLUSIONS

A significant conclusion of this research is that toxic monitoring devices designed for user safety may not always function reliably, subsequently exposing workers to toxic gas. The responses of the paper-tape monitors in reading TDI concentrations were affected by extreme, but common, measures of relative humidity. These fluctuations caused the monitors to read falsely, subsequently not warning the user of a potentially dangerous atmosphere of TDI. Exposure to a gas as harmful as TDI can cause severe health effects, drastically impairing a worker. The chronic effects of the gas may cause the individual to exhibit symptoms years after the exposure and the acute effects are extremely painful and dehabilitating. This calibration study was critical in that it tested the reliability of an instrument necessary for detecting a dangerous workplace atmosphere. It is important that studies such as this be made known to future users of paper-tape monitoring devices and that employees in hazardous workplaces be made aware of the discrepancies in technology presumably protecting their safety.

INTRODUCTION

The objective of this study was to observe the effects of carbon content on redox potential and fermentation products of flooded soils. The cycling of the element carbon in the environment is a well-understood phenomena. Carbon moves from the gaseous phase in the atmosphere to the solid phase in plant and animal tissue and then is either mineralized by decomposition or transformed back to the gaseous phase through respiration. However, the processes of metabolism differ greatly between terrestrial and flooded soils. In an aerobic soil, carbon is readily decomposed for respiration by soil microorganisms. This process takes place rapidly because oxygen, the preferred electron acceptor in the decomposition process, is plentiful. The predominant decomposition product is carbon dioxide and there is little carbon storage in the system.

In a water-saturated, oxygen-poor soil, carbon decomposition must be carried out by anaerobic decomposers. These anaerobic organisms function at a much slower rate than aerobic decomposers and use other ions such as NO_3^-, Fe^{3+}, and Mn^{4+} as electron acceptors in decomposition reactions (Ponnamperuma, 1972). Most carbohydrates are incompletely decomposed by these processes and form intermediate decomposition products such as low-molecular-weight organic acids and alcohols, and gases such as methane, hydrogen sulfide, and hydrogen gas (McKee and McKevlin, 1993). Due to the very slow breakdown process, called fermentation, the non-gaseous intermediate decomposition products tend to accumulate and much of the carbon deposited in an anaerobic soil remains undecomposed (Ponnamperuma, 1972). Therefore, flooded or hydric soils are much higher in organic matter content than terrestrial soils and provide an important sink for carbon.

The potential capacity of the soil to undergo oxidation-reduction (redox) reactions is called redox potential. Because oxygen is the preferred electron acceptor for these reactions, the lack of oxygen in a flooded soil causes the redox potential (Eh) to drop considerably. A lowered Eh value indicates the absence of oxygen as well as the presence of reduced forms of soil nutrients such as nitrogen, iron, manganese, and sulfur, which are substances used as reductants in place of oxygen. Redox potential is the single most important electrochemical property that distinguishes anaerobic soils from aerobic soils (Ponnamperuma, 1972).

Although much is known about the cycling of carbon and other nutrients through the environment, little information has been gathered on the fermentation products of decomposition in hydric soils. Different processes of anaerobic decomposition yield different products, and the availability of substrates for those different reactions hypothetically have an influence on the rate of formation and composition of fermentation products in the soil. The kinetic and thermodynamic characteristics of each reaction limit the rate at which it can proceed, and the varying availability of each substrate determine which reactions are dominant. Carbon content is one parameter that should have an effect on the rate of production and composition of fermentation products of a flooded soil

METHODS

Field collection. Soils were collected from a mountain bog in Graham County, North Carolina in May of 1996 and from a Carolina bay in Aiken County, South Carolina in 1993. The soils were air-dried, crushed, and homogenized, and all coarse materials were removed. The physical characteristics of pH, texture, cation exchange capacity, and organic carbon content of the soils were determined.

Soil Characteristics. Soil texture was determined with a hydrometer after removing organic matter with 10% hydrogen peroxide and suspending the soil samples with 0.5 N sodium hexametaphosphate (Gee and Bauder, 1986). Hydrometer readings were corrected for the temperature of the suspension water and the density of the dispersing agent. Soil organic matter content was determined by the dichromate oxidation method (Nelson and Sommers, 1982). The pH of each soil was measured in a 1:1 soil and water (weight to volume respectively) slurry. The cation exchange capacity of each soil was determined by a method similar to Plumb (1981). Exchangeable cations were first displaced using ammonium acetate buffered at pH 7. All samples were then washed with isopropyl alcohol to remove excess ammonium acetate. Finally, ammonium ions were displaced using a 10% NaCl solution and quantified using an ammonium electrode.

Development of GC/MS Methodology. Analytes were separated by gas chromatography and identified by mass spectrometry. Certain low-molecular-weight organic acids and alcohols were chosen as analytes because they were known to be common fermentation products. The method used on the gas chromatograph-mass spectrometer (GC/MS) was developed by adjusting the temperature programming of the instrument to achieve separation and detection of target analytes. Solutions of known concentrations of low-molecular-weight organic acids and alcohols were run under varying conditions to determine the optimum conditions for maximum analyte separation and identification. Two standards of high concentration were made for the common fermentation products. The alcohol standard included ethanol, 1-propanol, 1-butanol, 2-butanol, isopentanol, 1-pentanol, and the acid standard contained formic acid, acetic acid, propanoic acid, butanoic acid, and lactic acid. After achieving the best separation, the detection limit of each analyte was found by systematically diluting a solution containing only a single analyte. All acids were detectable at concentrations above 400 ppm. All alcohols were detectable at concentrations above 100 ppm except for ethanol which was detectable only above 500 ppm. However, when the standards were mixed the ethanol, formic acid, and lactic acid peaks were undetectable, even at concentrations of 1000 ppm. Therefore, only the presence of the other eight analytes were considered in this experiment.

Experimental Procedure. Three PVC columns were constructed for each soil (Figure 1). Each column was 17 cm tall with a PVC cap sealed with silicone sealant at the bottom. Each column was filled with soil to a depth of five centimeters, at which point a five-cm long segment of tygon tubing (8 mm inner diameter) was placed upright in the center of the column. A five-cm long rhizon soil moisture sampler was inserted in the tygon tube followed by sand that had been washed with hydrochloric acid and hydrogen peroxide. After placing soil around the tygon tube it was extracted, leaving a five centimeter column of sand to act as a filter surrounding the soil moisture sampler within the soil column. An additional five-cm layer of soil was placed on top of the sand filter and soil moisture sampler. A redox electrode was inserted into each soil column to one side of the soil moisture sampler. Then the columns were flooded with distilled water, leaving a two-cm layer of standing water at the top of each soil column. Soil solution was extracted from each soil column and the redox potential of each soil was monitored over a period of 50 days at intervals of 1, 2, 3, 4, 5, 7, 8, 10, 12, 14, 16, 18, 21, 24, 26, 28, 30, 35, 42, and 50 days. Distilled water was added to each column following the extraction of soil solution to maintain the two-cm water layer.

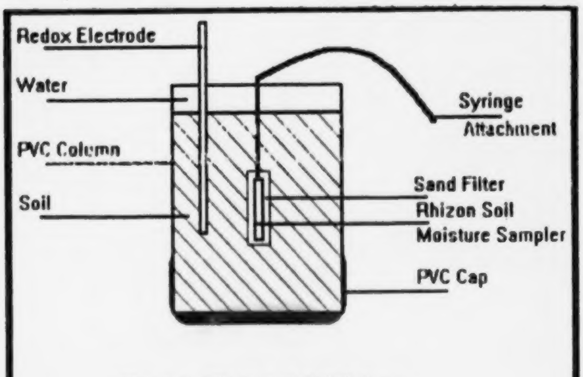

Figure 1. Diagram of Soil Column

On each sampling date the mass spectrometer was tuned and a standard containing all analytes at 1000 ppm was run. A 1-microliter sample of each soil solution was injected into the GC/MS and analyzed for the presence of analytes. Redox readings were corrected for the potential of the standard calomel electrode by adding 245 mV to each reading (Faulkner and Patrick, 1992). The fermentation products detected in the soil solution were analyzed in relation to redox potential and carbon content of the soil.

RESULTS

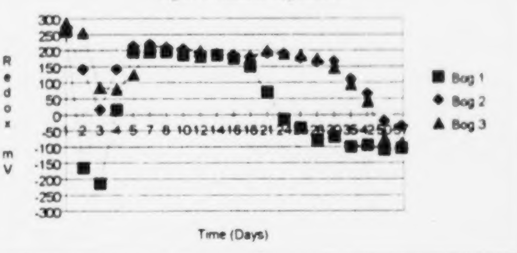
The two soils had very similar pH values and clay content (Table 1). However, the bog soil had more silt and less sand than the bay soil. The organic matter content of the bog soil was almost twice that of the bay soil. The CEC of the bog soil was much higher than that of the bay soil. This is probably due to the higher organic matter content.

Table 1 Soil Properties

	Mountain Bog	Carolina Bay
pH	4.19	4.26
% Organic Matter	13.3	6.9
CEC (cmol/kg)	31.4	17.9
% sand	44.9	59.6
% silt	41.7	23.0
% clay	13.4	17.4

The redox potential of all the samples showed similar trends (Figs. 2 and 3). After an initial dip over the first five days, redox decreased gradually until day 30, after which redox decreased more rapidly. This trend is characteristic of redox behavior in soils after flooding (Ponnamperuma, 1972). The exception to this general trend was the Bog 1 soil, the redox of

Figure 2 Redox of Bog Columns



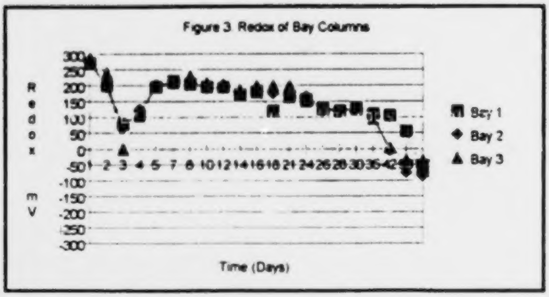


Figure 3 Redox of Bay Columns

which decreased dramatically after Day 18

None of the analytes were regularly detected in the bay samples Acetic acid was detected regularly in all three of the bog samples after a period of 14 days The certainty of computer identification of the acetic acid generally increased with time (Fig 4)

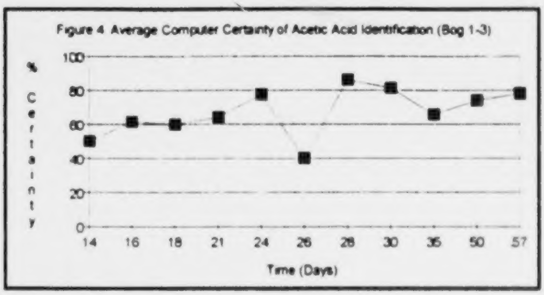

Figure 4 Average Computer Certainty of Acetic Acid Identification (Bog 1-3)

DISCUSSION

Redox values between 200 and -200 mV are considered characteristic of reduced soils (McKee and McKevlin, 1993) The redox of the bog and bay columns did not differ significantly although the carbon content of the two soils differed greatly Redox was consistently below 200 mV for all of the soil columns after Day 12 The bog columns showed acetic acid regularly after Day 14 while the bay columns did not Acetic acid appeared more frequently in Bog 1 before Day 14, and the redox of that column stayed consistently below 200 mV after Day 5 Acetic acid began to appear regularly in all the bog samples only after the redox of all three remained under 200 mV Acetic acid appeared only sporadically in the Bay samples, although the redox potentials were similar to those of the bog samples This suggests that the appearance of acetic acid was linked to greater carbon content of the bog soil

The results of the experiment were not as anticipated We consistently failed to detect lactic acid and ethanol, two of the more important fermentation products, in our standard Ethanol moved through the column almost as quickly as the solvent and could not be separated from the solvent Lactic acid was never identified as a solution component, even when a standard of commercial material was used This result is possibly a function of the specific nature of our GC column and the broadening of the sample peak into the baseline Also, lactic acid and ethanol can be metabolized by soil microorganisms into other substances like acetic acid (Ponnamperuma, 1972) Products could have been lost through these metabolic processes or by volatilization on contact with air in the sampling syringe

Our results suggest that the presence of acetic acid may be key in determining whether fermentation is occurring in a flooded soil The mountain bog soil, with an organic matter content of 13 3%, consistently yielded acetic acid, suggesting that for this soil fermentation begins to occur within two weeks of flooding The Carolina Bay soils, with only 6 9% organic matter content, showed no consistent pattern Further research could determine if acetic acid is the primary indicator product of fermentation One way to approach the problem is to conduct a similar experiment with soils containing more organic matter Another option is to refine the methodology, perhaps with a more sensitive detection method, and repeat the experiment If acetic acid is an indicator product, soils could easily be evaluated for the fermentation process

The Invasion of Carrotwood (*Cupaniopsis anacardioides*) A Study Comparing the Impact of an Exotic Species on two Islands in Sarasota, Florida

ABSTRACT

The Carrotwood tree is a native of Australia, but is commonly planted for landscaping purposes in southern Florida. After it escaped cultivation in the 1980s, it quickly established itself on mangrove and spoil islands where it thrives under the shade of Australian Pines and among coastal and inland mangroves. The species has recently been added to a Sarasota County ordinance (along with Australian Pine, Brazilian Pepper and Melaleuca trees), banning its future sale, transport and propagation. This is the first step in controlling Carrotwood growth. However, a lack of research into the species, particularly in southern Florida, limits the action county officials can take. Therefore, my thesis will focus on baseline scientific experiments that determine Carrotwood density as well as elevation and soil requirements. Two islands will be studied: John MacDonald island in Robert's Bay- formed completely from spoil, and Otter Key in Sarasota Bay- a natural island onto which spoil was dumped in the 1920s. These data will be used to compare the impact of the exotic species on two islands of different historical and vegetative origins and to evaluate environmental factors that may limit its growth.

BACKGROUND

The Carrotwood tree (*Cupaniopsis anacardioides*) is the most recent arrival of a group of exotic pest plants from Australia that were originally introduced to Florida as landscape plants. The species is a native of southeastern Queensland where it is common in depauperate rainforests along creek banks (Peter Mackey, personal comm.). Once thought to be "the perfect landscape tree", for the region (Newton, 1985), Carrotwoods began to escape from cultivated areas in the 1980s, and are currently invading the coasts of southern Florida - particularly mangrove and spoil islands. It is an aggressive species that can turn natural landscapes into dense exotic cover. Scientists with the bureau of Aquatic Pest Management surveyed the vegetation on over 100 spoil islands on the eastern coast of Florida. In 1988, no Carrotwoods were found, but a re-inspection in 1990 found many young Carrotwood plants (J. Jordan, personal comm., phide Oliver, 1992). Since Carrotwood is such a new arrival, not many of its natural history characteristics or distribution factors are known. Furthermore, there are no published scientific papers resulting from research conducted in Florida. This lack of information makes control and eradication of the pest even harder. Sarasota County has taken the first step by passing a stringent ordinance banning its sale, transport and propagation. Other coastal counties in Florida have passed similar, usually less strict, ordinances, but until more is known about the species and what affects its growth, control will be difficult.

To study the impact and habitat preference of non-cultivated Carrotwoods in natural areas, two islands were chosen for the analysis of plant density, soil salinity, soil pH and elevation. John MacDonald island (T37S R17E S1, Robert's Bay, Sarasota County) is a man-made spoil island created in the late 1960s. A relatively small strand of mangroves line the coast, while the interior is dominated by exotics - primarily Carrotwood and Australian pine (*Casuarina equisetifolia*). Unevenly distributed spoil piles are still evident in the ridge and swail system on which the vegetation grows. Otter Key is not a man-made island, but human intervention has played a minor role in the vegetational history of the island. In the 1920s, while the waterfront area of Sarasota was being developed, a plan arose to connect Otter Key to the mainland and develop it. This plan was never completed, but spoil was dumped onto the northern tip of the island and rows of Australian Pine trees were planted. However, the make-up of the two islands is drastically different. Otter Key is characterized by dense mangrove cover throughout the island and noticeably less exotic invasion. Human disturbance is less common because the vegetation is so thick in some areas that it is not possible to walk from one end of the island to the other. The hypothesis which forms the basis of my study is: the density of Carrotwoods will be different on these two islands because of the differential environmental characteristics of each island (i.e. pH, soil salinity, elevation).

METHODOLOGY

Four belt transects were set up on each island, beginning in areas of Carrotwood invasion (Transects 1, 2, 3 and 4 on John MacDonald Island and Transects A, B, C and D on Otter Key). Each transect was 25 meters long and 2 meters wide, consisting of five adjacent plots running in the same compass heading (the transects on John MacDonald Island followed the North-South compass line, while the transects on Otter Key ran parallel to the East-West compass line). Each plot was five meters long and two meters wide. All plants along the transect were identified, counted and placed into one of three size classes: Small (less than 0.5 meters), Medium (0.5 - 2 meters) and Large (taller than 2 meters). Carrotwood densities were calculated as number of plants found per square meter. Habitat type, disturbance and dominant species were also recorded for each plot.

Four soil samples were collected from each plot and analyzed for soil salinity and pH. Starting from the first plot, the samples were taken at 2.5 meter intervals, alternating between right and left side edges of the plots. Collections were made at two different depths from each of the sampling areas by using a soil auger. The auger was used to reach 9 inches into the ground, and again to take the second sample at 18 inches deep. The first depth, 0-9 inches, was labeled "X", while the second depth, 9-18 inches, was labeled "Y". Each time a sample was taken, a hand-held Kelway pH meter was used to find the pH of each sample before they were prepared for salinity analysis. Preparation and filtration of the samples followed the methods outlined by Head (1980) and Black (1965). All samples were allowed to air dry for a total of three days before being placed into the oven for further drying (the temperature in the ovens did not exceed 120 degrees Fahrenheit). After 24 hours, they were removed from the drying oven and placed into a sealed dessicator for an additional three days. This prevented the dry soil samples from collecting moisture from the surrounding air. All dry samples were crushed, passed through a 2mm sieve and prepared in a 1:1 soil to distilled water ratio. From there, they were filtered using a vacuum filtration apparatus. The filtrate was then placed onto a hand-held refractometer to record salinity.

The elevation of the transects was determined by using a combination of surveying techniques. Points of known elevation were found on the mainland by using city and county benchmarks. Differential leveling was used to transfer the established elevation of these points to the seawalls of two houses nearest the islands. Once the elevation was known, a computerized tachymetry level was placed on the seawall and a receiving prism was placed onto the island in sight of the level. The tachymetry level surveys in three dimensions, the level recorded the vertical and horizontal angles between the seawall and the island as well as the distance between the two points. The tachymetry level was then transferred to the island were the elevation was recorded for points of interest. In each plot, elevation was recorded at all four boundary pegs, soil sample locations, all Carrotwoods (with the exception of seedlings), other tree species that were taller than 2 meters and any point on the ground with noticeably higher or lower elevation. The information stored in the tachymetry level was used to plot points and construct contours.

RESULTS AND CONCLUSIONS

John MacDonald Island has a much higher density than was found on Otter Key. Figure 1 outlines the difference in densities between plots and between islands. Most of the density on John MacDonald was from seedlings, which were scarce on Otter Key. In fact, many plots on Otter Key had no Carrotwoods at all. Average Carrotwood density on John MacDonald Island transects ranged from 6.98 to 26.1 Carrotwoods per square meter, whereas the range on Otter Key was .29 to 1.68 per square meter.

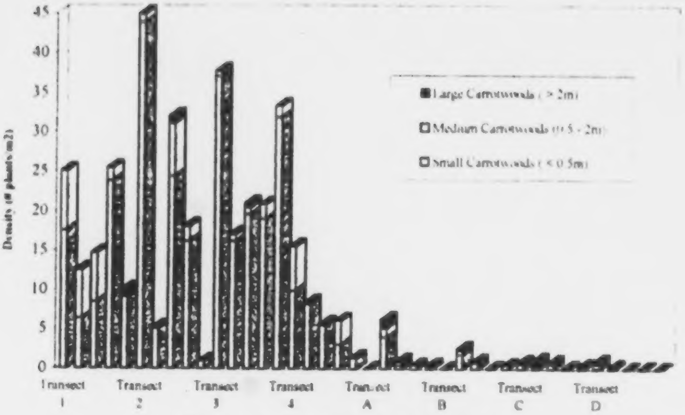

Figure 1: Carrotwood density in each plot.

Although there were a few plots on John MacDonald Island that were closer to sea level than any plots on Otter Key, in general, elevation on Otter Key was lower and less variable. Average elevation hovered around .85 meters. Extreme high and low elevations were not found on Otter Key, whereas the elevation fluctuated greatly between the plots on John MacDonald. This makes sense when you consider that the landscape on Otter Key is relatively constant: the interior is mostly flat, solid ground with even cover, surrounded by mangrove forest. Figure 2 shows the changing elevations on each island.

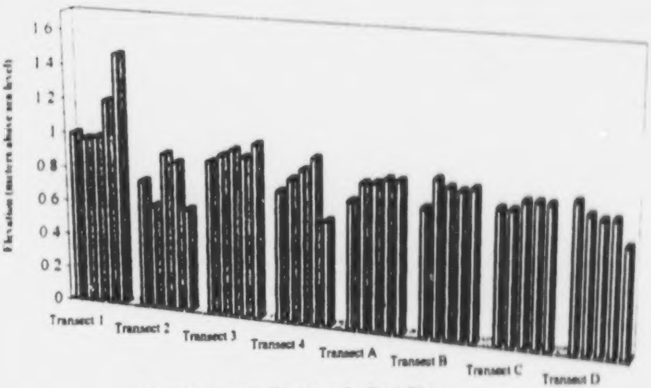

Figure 2: Average Elevation for Each Plot

A correlation was found between soil salinity and elevation. Plots with higher than average elevation were found to have lower salinity levels while more saline plots were usually those lower in elevation. Average salinity was 8.7‰ on John MacDonald Island and 6.8‰ on Otter Key. In plots were the salinity reached 15 or higher (the highest recorded was 35), the elevation never exceeded .80 meters above sea level, and sometimes dropped below 0.60 meters.

A correlation was also found between soil pH and elevation. Plots with higher elevations had pH levels close to 7, whereas surrounding plots were more acidic.

Elevation and specific soil characteristics are related to Carrotwood density on these two islands. However, there are no universal, overlying patterns that relate all of the variables. The pH range of Carrotwoods on these islands was found to be 6.1-6.8 (X) and 5.1-6.5 (Y). It is much easier to look at plots that have very little or no Carrotwood invasion, then examine their elevation and soil characteristics for an explanation. Figures 3, 4, and 5 show how Carrotwood density fluctuates with salinity and elevation.

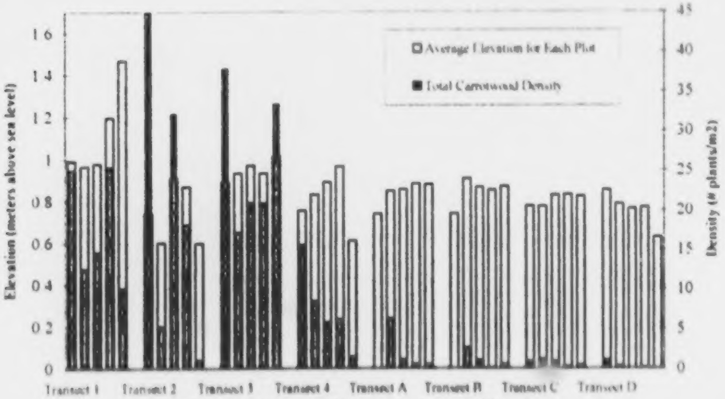

Figure 3: Carrotwood Density vs. Average Elevation

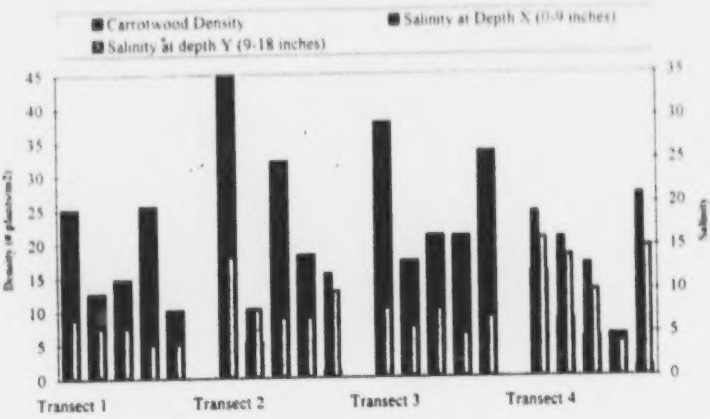

Figure 4: Carrotwood Density vs. Salinity on John MacDonald Island

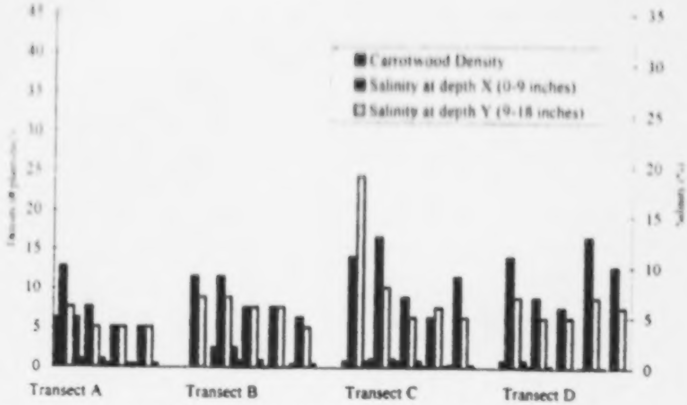

Figure 5: Carrotwood Density vs Salinity on Otter Key

By examining the elevation and soil pH and salinity of each of these plots, some patterns of Carrotwood growth and distribution can be explained. However, although theses are important factors affecting the growth and distribution of the species in Florida, there are many other environmental factors that, when working in concert with these factors, determine where Carrotwoods will grow. For example, Transect 4 on John MacDonald Island has areas of high elevation, neutral pHs and below average salinity levels. If only these three factors were taken into consideration, it would appear that Carrotwood density should be greater in this area. However, it is so close to the shore that the few Carrotwoods that have been able to establish themselves are frequently inundated and killed by the saltwater. This is an area on the island where Carrotwood density is actually the lowest. When trying to explain the growth patterns of Carrotwoods, it is important to consider other factors, such as light availability, exposure to salt spray, proximity to other plants (of the same or different species) and susceptibility to inundation. The data presented here, if analyzed in more detail, might also lead to patterns concerning different environmental requirements for Carrotwoods of different size, or how pH or salinity at different depths affect the growth of Carrotwoods differently.

These plants continue to be pests on the islands, invading inland mangrove habitats and producing dense Carrotwood thickets in some upland areas. Several individuals on each island have bloomed this year, and many other individuals are close in height and DBH to the blooming trees, indicating that they will soon be mature enough to reproduce as well. There has already been a Carrotwood population explosion, which will continue unless measures are taken to prevent or halt their growth and spread.

Urban Forests and Wildlife
A Web Document

Katrina M Simon
Dept of Biology
University of Richmond
Gottwald Science Center
Richmond, VA 23173
Advisor Dr John Bishop

ABSTRACT

Urban forests constitute over half the area of most cities These forests provide food and shelter for many urban wildlife species The present study examines the importance of forests to wildlife in urban areas Two districts of varying degree of urbanization were chosen as the study sites the Downtown District and the Far West End District The project includes the collection of data on trees in the Richmond region, assessment of wildlife common to Richmond and development of a Web document displaying research results A geographic information system, ArcView, was used to assess the interconnectedness of urban forests and wildlife The web document explains the use of geographic information systems in wildlife assessments and describes how characteristics of forests impact wildlife in urban areas The target group for this document are middle school students and educators in inner city Richmond

INTRODUCTION

Considerable potential exists in metropolitan areas for growing trees, shrubs, and other vegetation Many times, 60% to 80% of a city's area supports enough trees to meet the conventional definitions of a "forest" (Jones, 1995) Also common to the urban landscape are various wildlife species that have adapted well to the urban environment All wildlife must have four things to survive food, water, cover, and a place to live and reproduce (Grisom, 1994) The urban forests can provide three of these four necessities Often the survival of many wildlife species is dependent on the presence of urban forests Characteristics of the urban plant community influence wildlife in many ways

Urban forests provide homes and shelter for various kinds of animals Many types of bird's nests can be found in trees, often these nests are built of parts of trees, like twigs The white-tailed deer and red fox can often be found in wooded areas along urban edges (Mann, 1989) The urban forest also furnishes food for animals The eastern gray squirrel feeds mostly on nuts, flowers and buds of oaks, hickories, and a few other tree species (Mann, 1989) The eastern cottontail often eats green plants In the winter when green plants are scarce, cottontails eat woody plant parts like twig and bark of oak, dogwood, sumac, maple, and birch (Mann, 1989)

There are other indirect and less obvious ways in which vegetation influence wildlife The urban forest acts as buffers along streams and other waterways, soaking up nutrients washing from urban areas that might otherwise pollute these waters (Alore, 1995) Plants also help control soil erosion that would render ponds unsuitable for many water animals Urban wildlife like the mallard duck, snapping turtle along with various types of frogs are able to find suitable habitat in urban areas in part due to the presence of urban forests (Alore, 1995) Additionally the urban forests helps some wildlife by producing leaf litter Many animals make their homes in the leaf litter The red-backed salamander spends it entire life in leaf litter and underground (Glass, 1986)

Tree condition is important to wildlife Healthy trees will produce abundant amounts of food and provide strong shelter for animals Dead trees also offer benefits to wildlife and in actuality have great ecological value Many animals use the hollow of dead trees as their home The wood duck and barn owl use natural cavities in trees as nesting sites (Ross, 1983) Pair of raccoons often rests in the hollow of trees (Ross, 1983) A branch that falls on the ground or a log that may be present on the ground can provide a home for smaller animals like the red-backed salamander or a toad or frog A dead tree trunk will also attract a woodpecker (Ross, 1983)

This project characterizes urban forests in two districts of the City of Richmond the Downtown District and the Far West End Districts. Each district is evaluated based on tree species composition and health. The data is analyzed using a geographic information system (GIS), ArcView. The end product is a highly interactive, multimedia web document examining the urban forests in the two districts using ArcView to predict the types of wildlife and spatial occurrence associated with each of the two districts. The document is directed toward middle school inner-city students in the City of Richmond. Information inputted into ArcView on tree species and condition allows the student to predict the types of wildlife present in certain areas of the city.

MATERIALS and METHOD

Data Collection. Data on trees collected by City of Richmond officials were procured and served as the main source of vegetation data. Data was "ground truthed" via aerial photographs and field observations. The abundance and health of trees at 450 sites were measured. Tree species were identified and the health of each tree was rated as either good, fair, poor, dying or dead. Library research was conducted to obtain information on the types of food and shelter a particular type and condition of tree provides. Information was collected on wildlife largely through library research. Primary information sought was habitat requirements, eating behaviors, urban affinity, and how these characteristics relate to urban forests. Information was also obtained from the Department of Game and Inland Fisheries.

The Study Sites. The City of Richmond divides the city into nine districts. The boundary of these districts were kept intact for the purposes of the project. Ideally all nine districts would have been studied however due to time and resource constraints, the Far West End and Downtown Districts were chosen as the study sites. These two sites represent varying degrees of urbanization that affords an opportunity to study wildlife and vegetation along an urbanization continuum.

. Data Analysis. The types of trees present in the Downtown and Far West End Districts were analyzed. The most abundant trees in each district were noted. In addition to tree species, the condition of the trees in each of the two districts was investigated. Thus the two characteristics of trees focused on were tree type and condition. The geographic information system, ArcView, was used to couple the tree data with wildlife. Layers with tree species and health were created and overlaid on the City of Richmond. From these maps, predictions about the types and spatial arrangement of wildlife present in each district were made.

The Web Document. All of the preceding information was incorporated a Web document. The Web document target group is middle school students and educators in urban areas, particularly in the City of Richmond. These efforts culminated in an interactive document that teaches students about urban forests and wildlife in the City of Richmond.

RESULTS

Over 100,000 trees were found in the City of Richmond and most were in poor health. Tree composition varied slightly by district, but, for the city as a whole, oaks and maples were the most abundant trees but quite a few other trees were found. Linden, zelkova, and ginkgo were fairly common to the City of Richmond as well. The Downtown site and the Far West End site differed in vegetation composition and number (Fig. 1). The Far West End District contained a greater number to trees than the Downtown District. The most abundant trees in the Far West End were the oak, maple, linden, and pine. The most abundant trees in the Downtown District were the oak, zelkova, maple and elm. The Downtown District possessed a greater percentage of trees that were in good health (Figs. 2 and 3).

DISCUSSION

Middle school inner city students were chosen as the target group for various reasons. This document serves a twofold purpose, (1) to introduce the student to ecology and (2) to acquaint the student with computers. It is recognized that most inner city schools are lacking in science instruction. This document is a means by which a great number of students can be introduced to urban ecology. This introduction is very pertinent to the lives of the target audience in that urban forestry and wildlife can be observed and studied in and around their neighborhoods and schools. With this document, it is hope that a sense of curiosity will be ignited for ecology. Secondly, computer skills are paramount for the future By bringing urban ecology to students via the internet, they are introduced to computers by the mere fact that the mode of communication is through the Web Furthermore, the document demonstrates how the use of GIS software has applicable uses and facilitates a better understanding of the world around us

Many hours of hard work went into designing the Web document to make is as appealing, interesting, and educational as possible to the target audience In doing this, the document utilized advance computer capabilities This document definitely on the cutting edge of technology The document is a multimedia show in which color pictures, maps, and other graphics illustrating points are flashed on the computer screen as a dialogue is heard is the background explaining the material Bullet summaries of the important points of the dialogue also appear on the screen The main character, Sandra, is modeled after an actual student who attends school in the City of Richmond Sandra visits a fictitious character known as Dr Greenetree, who shares with her information about Richmond's urban forests and wildlife The two characters discuss urban wildlife and forests as they tour the City of Richmond pointing out relevant sites along the way It is hoped that many of the areas featured in the document will be familiar to the target audience

The importance of GIS to this project cannot be stressed adequately It is the basis of the project that enables the student to indicate where the predicted wildlife will occur The use of GIS within this document was kept on an elementary level to meet the needs of the target audience However, the uses of GIS extend much further beyond the realms defined here In future modifications of this document, more extensive and in-depth use of GIS will be incorporated

There are several weaknesses of this project Information was presented as clearly and accurately as possible, however, assumptions had to be made about wildlife habitat preferences when predicting wildlife associations with various types of plants The underlining reasoning the document is based in is that since vegetation abundance and type influences wildlife and the vegetation differs in the Downtown and Far West End Districts then the wildlife in each area differs The characteristic wildlife of the two districts will differ based on these vegetation differences Exactly what these differences are can only be assessed in the field The conclusions drawn in the document are based on literature research, not field research which may present certain weaknesses

Regardless of the shortcomings of the project, it is hoped that students will find the document educational and beneficial in many ways Ultimately, it is hoped that the document will be adopted into the City of Richmond School System

Effects of Stratification on Germination of Two Oak Species in Southeastern Arizona

Kimberly Suedkamp

School of Renewable Natural Resources
University of Arizona
Biological Sciences East Building
Room 325
Tucson, AZ 85721

Faculty Advisor:

Guy R. McPherson

The goal of this experiment was to evaluate the roles of stratification time and pre-storage water immersion temperature on the proportion and rate of germination of two oak species in southeastern Arizona. 1,200 *Quercus emoryi* (Emory Oak) acorns were subjected to each of twelve possible treatment combinations of: stratification for 0, 40, 80, or 120 days and water immersion at 4, 25, or 45 degrees Celsius. Due to limited availability, *Quercus oblongifolia* (Mexican Blue Oak) acorns were only subjected to stratification treatments for 0, 40, or 80 days. Germination of *Q. emoryi* was affected by stratification ($P<0.0001$), but there was no main effect or interaction of water immersion temperature. Average *Q. emoryi* germination time decreased 4-fold and percent germination increased 10-fold after 80 days of stratification. Average *Q. oblongifolia* germination time decreased 14-fold after 80 days whereas maximal germination (12%) was obtained after 0 days of stratification.

INTRODUCTION

Oak woodland communities in southeastern Arizona provide important resources for humans and wildlife. Specifically, oak woodlands supply timber and firewood for humans in addition to food and shelter for wildlife. Oak woodlands at low elevations are dominated by *Quercus emoryi* Torr. or *Quercus oblongifolia* Torr. *Q. emoryi* is a member of the subgenus Erythrobalanus (red or black oaks) in the family Fagaceae. Typically, stratification enhances germination of members of this subgenus. However, previous studies of *Q. emoryi* in Arizona reported that stratification did not increase germination rates or proportions after 30 days (Nyandiga and McPherson 1992). Little information is available on the germination requirements of *Quercus oblongifolia* Torr., a member of the Erythrobalanus subgenus (red or black oaks). Prior observations have noted that acorns of this species typically mature beginning in November. Most *Q. oblongifolia* acorns had already reached maturity and fallen off the parent tree in mid to late October of 1996. The difficulty we encountered in predicting the timing of acorn maturity accentuates the need for determining information about phenology and germination requirements for this species in arid regions of the southwest.

Seed predation by herbivores and parasites, particularly weevils in the *Curculio* genus, may decrease germination of oaks. Occupation by weevils usually results in a decline in moisture content leading to acorn mortality. The goal of our experiment was to evaluate the roles of stratification time and pre-storage water immersion temperature on the proportion and rate of germination of low-elevation oaks in the southwestern United States.

METHODS

Q. emoryi acorns were collected at maturity in lower Garden Canyon.

Huachuca Mountains, and O'Donnell Canyon, Canelo Hills on 12 July 1996. *Q. oblongifolia* acorns were collected from Molina Basin, Santa Catalina Mountains, and Madera Canyon, Santa Rita Mountains, during mid to late October 1996. After collection, all acorns were inspected for weevil occupation and other damage. Acorn caps were removed without tearing the seed coat and subsequently float-tested as a screen for premature desiccation (Germaine et al. 1997; Gribko and Jones 1995).

Germination trials were conducted in a Percival model growth chamber with fluctuating 12 hour day and night cycles at 30 and 20 degrees Celsius, respectively. Germination medium was moistened filter paper inside a petri dish. Petri dishes were treated as replicates and randomized every 3 days. Each replicate received water every other day and antifungal treatment (Captan) as necessary. Stratification medium was moistened silica sand in a petri dish stored at 4 degrees Celsius for 0, 40, 80, or 120 days. Immersion medium was tap water at 4, 25, or 45 degrees Celsius for 45 minutes in a controlled-temperature water bath.

1,200 *Q. emoryi* and 225 *Q. oblongifolia* acorns were utilized in germination tests. *Q. emoryi* acorns were subjected to 12 different combinations: stratification period (0, 40, 80, or 120 days) and immersion temperature (4, 25, or 45 degrees Celsius). Due to limited availability of acorns, *Q. oblongifolia* acorns were subjected to stratification periods of 0, 40, or 80 days. Within each *Q. emoryi* treatment there were 10 replicates of 10 acorns. Within each *Q. oblongifolia* treatment there were 5 replicates of 15 acorns. Germination was defined as a radicle length of at least 3 mm. All germination trials were maintained for 2 weeks after the last observed germination or 40 total days, whichever occurred first.

RESULTS

Germination was affected by stratification ($P<0.0001$), but there was no main effect or interaction of water immersion temperature for *Q. emoryi*. Average *Q. emoryi* germination time decreased from 21 days without stratification, to 9 days after 40 days of stratification, and to 5 days after 80 days of stratification. *Q. emoryi* percent germination increased from 4% without stratification, to 43% after 40 days of stratification. Longer stratification periods did not affect germination ($P>0.15$). Average germination time for *Q. oblongifolia* decreased from 14 days without stratification, to 4 days after 40 days of stratification, and to 1 day after 80 days of stratification. Average percent germination of *Q. oblongifolia* was maximal (12%) after 0 days of stratification, decreased to 2% after 40 days, and was 6% after 80 days of stratification. Water immersion had no effect ($P>0.13$) on percent germination or germination time of either species.

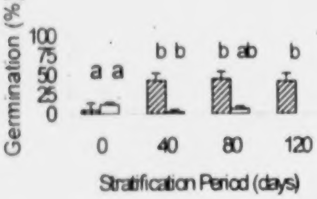

Figure 1. Average percent germination of *Quercus emoryi* (filled bars) and *Quercus oblongifolia* (open bars). Within a species, standard error bars with the same letter do no differ ($P>0.05$).

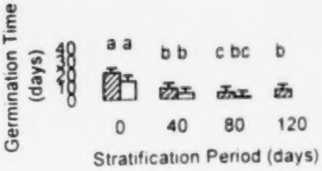

Figure 2. Average germination time of Quercus emoryi (filled bars) and Quercus oblongifolia (open bars). Within a species, standard error bars with the same letter do no differ (P>0.05).

DISCUSSION

Contrary to findings in earlier studies (Nyandiga and McPherson 1992), these results indicate that Q. *emoryi* germination is clearly enhanced by stratification. Stratification for 40 days decreased average germination time nearly 3-fold. Furthermore, percent germination increased 10-fold after 40 days of stratification relative to non-stratified acorns. Stratification for longer than 40 days did not produce additional increases in percent germination. Water immersion treatments did not affect percent germination or germination time. Therefore, these results indicate that a 40-day stratification period provides an appropriate stratification treatment to maximize percent germination and minimize germination time.

Subtle differences in handling techniques and an atypically dry year may have produced germination responses contrary to those observed previously. Acorn processing in this study was done immediately after collection (within 12 hours of collection) whereas Nyandiga and McPherson (1992) may have allowed one or more days to elapse prior to the completion of acorn processing. Young and Young (1992) observed that acorn moisture contents below 20-30% in the Erythrobalanus genus were lethal. Bonner (1996) reported lower tolerable moisture contents (10-15%) for the same subgenus. Bonner (1996) also reported that 25% of acorns with moisture levels below lethal thresholds would survive if rehydrated within 48 hours.

Germination time for Q. oblongifolia decreased 3-fold after 40 days of stratification, and 14-fold after 80 days of stratification. Percent germination was highest (12%) in the 0 day stratification treatment and decreased to 2% after 40 days of stratification.

NATURAL RESOURCE MANAGEMENT IMPLICATIONS

These results have important implications for the maintenance and regeneration of oak woodland ecosystems in southeastern Arizona. Increased population levels have subjected these communities to higher utilization and visitation levels than previously experienced. Urban developments and agricultural fields have been replacing oak woodlands in order to satisfy human demands. To maintain oak woodlands on a sustainable basis, resource managers need to concentrate on protective solutions before the option of regeneration is not available. The practical tools presented here will allow resource managers to achieve higher success rates in terms of increased total germination and decreased germination time. Limited funding for ecosystem conservation mandates the development of economically feasible maintenance and regeneration tools. Maintaining oak woodlands on a sustainable basis appears to be an economically feasible long-term option.

Seasonal Fluctuations in Central Greenland Ice Sheet Radar Altimeter Return Characteristics

Philip Dennison

Earth System Science Center
The Pennsylvania State University
248 Deike Building
University Park, PA 16802

Faculty Advisor: Richard Alley

Geosat altimeter returns from an area of the Central Greenland ice sheet were analyzed for spatial and temporal patterns. Return waveforms were geographically divided into twelve 1° latitude by 2° longitude cells, and then averaged for 21-day and 17-day periods. The maximum slope of the mean cell waveform and an averaged Automatic Gain Control (AGC) value were calculated. Spatially, cell mean maximum waveform slope and AGC strongly correspond to changes in surface slope over the study area. Temporally, maximum waveform slope and AGC exhibit seasonal cycles. Maximum waveform slope displays a biannual cycle with maxima in the summer and winter and minima in the spring and fall. AGC values demonstrate an annual cycle characterized by large drops during the fall months. Changes in snow surface properties are most likely responsible for the seasonal variability in maximum waveform slope and AGC. Surface roughness, snow grain size, and snow density, as determined by wind speed, temperature, and precipitation, influence the shape of the return waveform and the percentage of power returned.

BACKGROUND

Satellite radar altimetry has traditionally been used to measure the elevation of low-slope water, ice, and snow surfaces. Altimeter return characteristics can also reveal information about snow surface properties. The satellite emits a microwave pulse and then records power returned versus time as a waveform. Surface and volume scattering from snow can affect the shape of the return waveform. Snow properties, including surface roughness, snow grain size, and snow density, influence surface and volume scattering. Ridley and Partington (1987) and Davis and Moore (1993) have developed return waveform-fitting models containing snow property terms.

Surface slope is very important in determining the shape of the waveform and the percentage of power returned. Steeper surface slope produces a larger radar footprint. A larger footprint returns the radar pulse over a longer period of time, effectively stretching out the waveform. Larger slopes also scatter more radiation in non-nadir directions, returning less power to the altimeter. Surface roughness is a primary contributor to surface scattering of microwave radiation. Rough surfaces lengthen the period of the return and lower the percentage of emitted power returned to the altimeter. Snow grain size and snow density affect volume scattering. Smaller snow grain size and lower snow density both increase the amount of volume scattering in a snow body. Volume scatter-dominated waveforms typically have lower slopes than surface scatter-dominated waveforms.

METHODS

Geosat radar altimeter data returned from Central Greenland over a period of two years (1987-88) were analyzed for spatial and temporal trends. A study area in Central Greenland (Figure 1) was situated well away from higher slope areas of the ice sheet. Surface slope in the study area did not exceed 0.5° at a resolution of 5 minutes. The study area was divided into

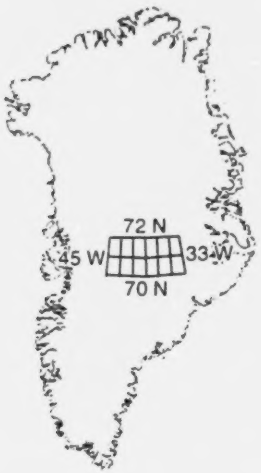

Figure 1. The study area, Central Greenland.

twelve 1° latitude by 2° longitude cells to control for slope effects. For each cell, 21-day averages of waveform shape and the Automatic Gain Control (AGC) were computed. AGC adjusts the sensitivity of the altimeter receiver, and is directly related to the amount of power returned. The 17-day period averages were also calculated to ensure the validity of the 21-day averages. The maximum slopes of the average waveforms were derived for each of the cell-periods. Normalized cell-mean maximum waveform slope and AGC were then combined by averaging the values over the entire study area.

RESULTS

Maximum waveform slope and AGC varied inversely with surface slope. Cells with steeper surface slopes tended to have low maximum waveform slope and AGC values. This spatial pattern was expected, because surface slope is known to contribute significantly to the shape of the return waveform and the power of the return. Steeper-slope regions of the study area had larger footprints and increased off-nadir scattering, lengthening the time of the return, thus lowering the slope and reducing the total power returned.

The temporal variations witnessed in both the 21-day and 17-day periods were much more complex. Both maximum waveform slope and AGC exhibited seasonal cycles. Maximum waveform slope displayed a biannual signal, with high values occurring in summer and winter months and low values occurring in spring and fall (Figure 2). AGC showed a more annual signal, with a sharp drop in AGC values during fall months (Figure 3). A much smaller minimum in AGC, corresponding to the spring minimum in maximum waveform slope, was evident. When plotted together, maximum waveform slope and AGC display similar trends (Figure 4). The two return measures experience similar temporal oscillations.

DISCUSSION

The discovery of a seasonal signal in Greenland radar altimetry data is not unprecedented. Andersen (1994) calculated annual variations in altimeter-determined elevations using one and a half years of ERS-1 data. The annual variation, which Andersen attributed to winter snow accumulation and summer melting, was lowest in the central part of the ice sheet. Andersen speculated that annual variation is near zero for the central ice sheet, where melting does not occur on an annual basis.

Seasonal changes in surface roughness are the most likely cause of the temporal fluctuations in maximum waveform slope and AGC. Through the construction and destruction of snow dunes, wind can alter the surface roughness of the Greenland ice sheet on a scale from

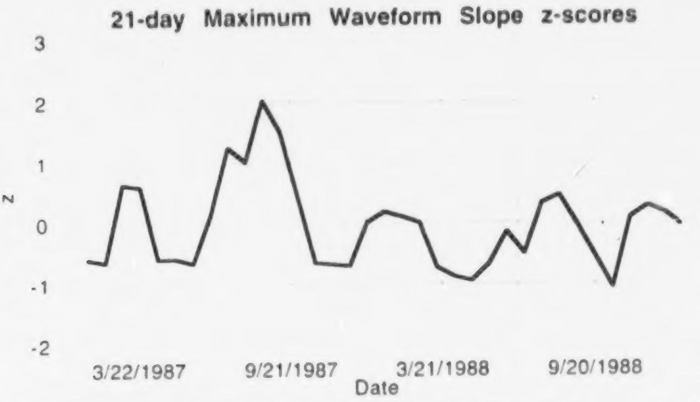

Figure 2. 21-day maximum waveform slope. Note high maximum slopes in the summer and winter, and low maximum slopes in the spring and fall.

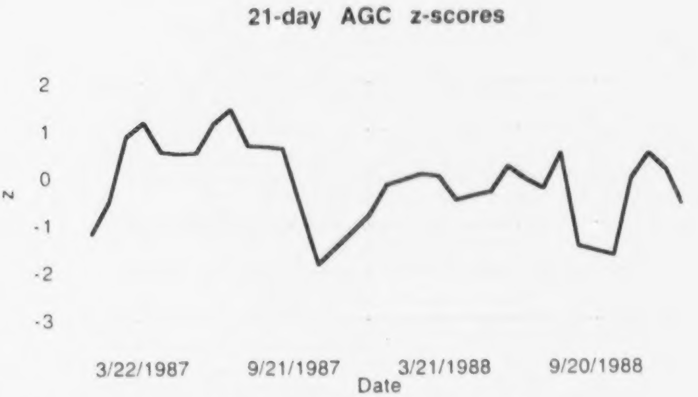

Figure 3. 21-day AGC. Note the large drops in AGC values in the fall.

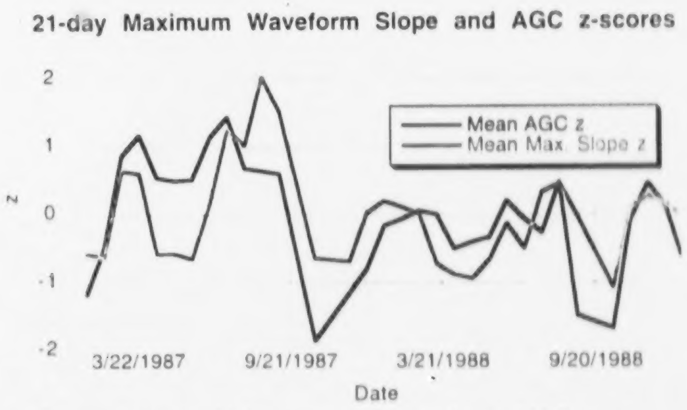

Figure 4. Comparison between 21-day maximum waveform slope and AGC z-scores.

centimeters to meters. Unfortunately, wind speed records for the interior of Greenland are short in duration and sparse in spatial coverage. Only a few months of wind speed data from an Automatic Weather Station (AWS) were available for the study period. The duration and quality of these data were not sufficient to merit detailed analysis. Better AWS data from 1991 point to an annual cycle for wind speed, with a maximum in late February to early March and a minimum in July, August, and September.

The timing of this cycle does not support seasonal fluctuations in wind speed as an influencing factor in the temporal variability witnessed in maximum waveform slope and AGC. The late-winter peak in wind speed corresponds to high values of both maximum waveform slope and AGC, which are associated with a smoother surface. Low maximum waveform slope and AGC values, which indicate increased surface roughness, occur in the spring and fall, when wind speed is changing. Although wind speed does not appear to play a major role in the determination of annual fluctuations in maximum waveform slope and AGC, it is possible that wind speed is a minor influence, or that changing wind speed reorganizes snow dunes, causing a lowering of maximum waveform slope and AGC values, or that the seasonal behavior of wind speed values were different during the study period and during the period of wind data collection.

Other factors that could influence the determination of temporal fluctuations in maximum waveform slope and AGC include precipitation and temperature, which affect centimeter and millimeter scale surface roughness, grain size, and snow density. Precipitation in Greenland generally peaks in the warmer months of June to September and is lowest in late winter (Shuman and others, 1995). The Greenland ice sheet is also warmest during the summer. Both higher temperatures and new snow produce larger grain sizes and less dense surface snow. The summer increase in maximum waveform slope supports a summer rise in surface scattering caused by increased snow grain size. The winter peak in maximum waveform slope, however, cannot be explained by snow grain size and snow density effects. Clearly, precipitation and temperature alone are insufficient to explain the seasonal variations seen in maximum waveform slope. Diurnal temperature changes during the spring and fall could have effects on surface roughness or snow grain properties, or snow density layering could influence return characteristics. There is no evidence to support these conjectures, however.

CONCLUSIONS

Central Greenland radar altimeter return characteristics, measured through maximum waveform slope and AGC, exhibit seasonal fluctuations for the years 1987 and 1988. Maximum waveform slope displays a biannual cycle, while AGC demonstrates a generally annual cycle. Both waveform measures are probably influenced by snow surface characteristics, although wind speed, precipitation, and temperature alone do not appear to be significant contributors to either cycle. Further definition of the biannual variability in return characteristics will require the fitting of a waveform model, which will allow the discrimination of which scattering type is causing the seasonal signal. If perfected, the ability to determine changes in snow surface characteristics using radar altimetry promises to be of great utility in detecting climatic change, which could presumably alter the characteristics of the seasonal cycle.

ACKNOWLEDGMENTS

The author would like to thank the Hughes STX Ice Altimetry Group for contributing radar altimetry data and data processing support, and Dr. Charles Stearns at the University of Wisconsin-Madison for providing AWS data.

Boulder, CO 80309

Faculty Advisor:
Prof. Anne Sheehan

ABSTRACT

Though the products of past tectonic activity are structurally evident along the Front Range of Colorado, modern seismicity has been relatively quiet, though not completely inactive. An earthquake of approximate M 6.6 (Spence et al., 1996) occurred in north-central Colorado in 1882, and a cluster of moderate injection-induced earthquakes occurred in 1967. Despite the ample geologic evidence for Quaternary fault movements, the seismicity of the Front Range has remained largely unstudied. The first microseismic data for the Front Range was only recently published.

During the fall of 1996, a local seismic network was deployed across the Front Range near Boulder to record local activity as part of a Field Geophysics course at the University of Colorado. These stations were supplemented by two other stations, operated by the United States Geological Survey, in Golden and Idaho Springs, Colorado.

Twenty-three small earthquakes were located within an approximate 50-mile radius of Boulder during a total of forty-five recording days. The earthquakes ranged from magnitude 0.2 to 2.0 on the Richter scale. The smallest earthquake that can be felt is about a magnitude 3, and an earthquake of magnitude 3.5 can cause slight damage. The levels of microseismicity for the study region are about thirty times less than those of the California/Nevada region and about twice as much as New England.

Using the crustal velocity model proposed by Prodehl and Lipman (1989) for the Denver basin, epicenter locations were determined for all local events. We have constructed a map of these epicenters. The most quake activity was located west and northwest of Golden. The microseismic distribution will help isolate faults which may still be active and perhaps to locate previously unknown faults. An understanding of fault locations and activities will lend insight into the dynamics of the Laramide orogeny and also the modern tectonics of the area.

ACKNOWLEDGEMENTS

My thanks to Prof. Anne Sheehan, my thesis advisor, for the opportunity and assistance in this project. I appreciate the input provided by Dr. Hartmut Spetzler and Dr. Nel Caine. I am also grateful to Dr. Craig Jones for his input regarding data analysis and invaluable help with graphics applications. Thanks also to Dr. Kenneth Deuker for his assistance in data analysis techniques and field work. Furthermore, I'd like to thank the Field Geophysics class (GEOL 4740) who helped in installation. For providing property for station sites, I wish to thank Robert Erickson, Linda Figueroa, Jody Hvorka, and the employees of the Table Mountain Observatory (especially Glenn Sasagawa and Dan Winster). Funding was provided by the National Science Foundation through the Undergraduate Education Program and the Research Experience for Undergraduates Program. Further funding was provided by Cooperative Institute for the Research of Environmental Sciences (CIRES) through the Colorado Commision for Higher Education. Thanks also to Sally Mae for her patience.

INTRODUCTION

Seismicity is the frequency of earthquakes occurring within a given area. Microseimicity is the frequency of small earthquakes that occurr within this area. An earthquake is generally considered small if it has a magnitude less than M 3. Magnitude

BEST COPY AVAILABLE

simply refers to the energy, or strength, of a seismic event. A magnitude of M 3 is roughly the level at which an earthquake can be felt by humans. In general, the smaller an earthquake is, the closer together the recording instruments (referred to as seismometers or sensors) need to be to record the event and locate its source (or epicenter).

The level of microseismicity (or the amount of small earthquakes) along the Front Range of Colorado is poorly known. A map of the historic seismicity of Colorado has been produced (USGS, 1993). This map includes events from 1800 through 1993. It is a compilation of events that were recorded instrumentally (with seismometers), historical accounts of earthquakes felt by people and damage incurred, or both. This map is useful in determining areas of generally higher seismicity from areas of generally lower seismicity. However, since it relies largely on earthquakes that were felt and on earthquakes recorded by a sparse network of sensors, it is not useful for determining the levels of microseismicity of a particular area.

One previous microseismic study had been done specifically for the Front Range of Colorado and another in the Paradox Valley / Ridgeway area. The results were used to produce a map of the microseismicity recorded during a six month period. This map, however, covers a large area. It's resolution is not fine enough to pick up the multitude of smaller events that only a closely-spaced, local array can. Therefore, this map is useful because it lends insight into the larger-scale, general microseismicity levels of the Front range. However, it is not useful in determining the smaller-scale events of a very localized area, such as the Boulder-Golden region. This map did show a pattern of microearthquake occurrence that matches a pattern which showed up on our new map. This correlation is probably significant and will be discussed later.

The contemporary crustal stress regime in Colorado has been the subject of some debate and has only recently begun to be understood. Colorado seems to be extending along a roughly northeast-oriented axis. (Bott and Wong, 1995). A possible mechanism for seismogenesis in the area is reactivation of existing faults (possibly thrust faults dating back at least as far as the Laramide orogeny, 50-70 million years ago) which are oriented favorably to the contemporary stress field, i.e. oriented west-northwest to northwest (Bott and Wong, 1995). The presence of fault scarps between the ages of 5,000 and 15,000 years along the Rio Grande rift is further evidence of recent extensionally-driven seismicity in the region (Colman, 1986). Furthermore, focal mechanisms of two of the earthquakes related to the Rocky Mountain Arsenal fluid injection have indicated normal (or extensional) fault movement locally in the northern Front Range region (Wong, 1986).

The goal of the present project was to set up a very localized array around Boulder and Golden, Colorado, in order to accurately map local microseismicity patterns. Using three sensors of our own, and incorporating data from two other local United States Geological Survey (USGS) sensors, we set out to record very local earthquakes within a radius of approximately 50 km of the array. This area includes Boulder, Denver, Golden, Idaho Springs, Ward, Ft. Collins, and the Continental Divide region from near Eisenhower Tunnel in the south to about Long's Peak in Rocky Mountain National Park to the north. Within this small region, we hoped to record seismic events as small as M 0. The short spacing between the stations of this array was designed to facilitate this.

RESULTS

Many of the seismic events recorded occurred during the day. This would seem to suggest possible sources other than earthquakes because earthquakes should be random in time. Figure 2 shows a histogram of the number of events recorded (natural or otherwise) from the USGS station in Golden during certain hours of the day. The events seem to increase in number during daylight hours. However, it is important to note that the data from our three stations is biased towards daylight hours. This is due to the fact that the array had a tendency to turn off at night. This became more of an issue as time progressed toward the winter solstice and as the sun progressed lower in the sky. The station near Sugarloaf Mountain (SUG) was especially susceptible to this, as it was located in a forest clearing where trees hid the low-angle sunlight from the solar panels.

Figure 1 contains the final map of earthquakes. It shows locations, magnitudes, error ellipses, and station locations. The map seems to depict an alignment of earthquakes running in a southeast to northwest direction. This alignment is located just west of Golden. The map also shows a clustering of events near a known hard rock quarry where possible blasting may occur. Other events seem to be randomly distributed.

Figure 3 depicts what is known as a b-value plot. It depicts earthquake occurrence (on a logarithmic scale) versus earthquake magnitude. These plots define a roughly straight line. Also included in this figure are the plots for seismicity levels in the California/Nevada and New England regions. The seismicity levels indicated by this project seem to fall in between these two seismicity levels.

DISCUSSION

Most of the events recorded in this project occurred during the day. This may have been caused by a systematic biasing of data towards daylight hours resulting from stations 'powering down' at night. However, the histogram (see figure 2) from the USGS Golden station seems to indicate that seismic activity does indeed increase during the day. This suggests the possibility of mine blasts as significant seismic sources. This is further supported by the apparent clustering of seismic events near a known hard rock quarry in Clear Creek Canyon. These events are probably mine blasts. The fact that they cluster at a known mine (see figure 1) is encouraging because it indicates that the locations achieved through HYPOINVERSE were accurate. The remainder of the events were not clustered and can be considered natural seismic events, or earthquakes.

The apparent alignment of events west of Golden may delineate an active fault. The results of this project by themselves may not be enough to suggest this. However, an examination of the map produced in a previous study also showed an alignment of earthquakes in approximately the same orientation. This strongly suggests the presence of active movement along a fault oriented in a northwest-southeast direction located just west of Golden. This orientation correlates well with the seismogenesis characteristics previously proposed [Bott and Wong, 1995; Wong, 1986]. The earthquakes produced by this fault could indicate the reactivation of a pre-existing fault in response to regional extension.

The b-value plot resulting from this project (see figure 3) suggests a seismicity level for the Front Range that seems about thirty times less than that of the California/Nevada region and about twice that of New England. An extrapolation of the line for this region suggests a recurrence interval for a magnitude 6 earthquake to be between 100 and 1000 years. However, the window of magnitudes sampled by this project is narrow and this extrapolation is tenuous. A permanent array in the area would do a better job of producing an accurate b-value plot.

Also, the alignment of events along the northwest-trending fault near Golden may represent a smaller, more seismically active area. A b-value plot for this region could possibly reflect a shorter recurrence interval for a large earthquake. Not enough data has been collected to determine this. However, it is a serious consideration, especially due to the fault's proximity to the Golden/Denver metropolitan area. Further study is needed to adequately evaluate the seismic hazard potential of this fault.

CONCLUSIONS

Overall, the array recorded and located 23 microseismic events over a total recording time of about 45 days. These microseismic events ranged in magnitude from M_L 0.2 to M_L 2.0. Three of these seem to be a result of blasting in the area. The remainder are natural microearthquakes. An alignment of microearthquakes along a northwest-southeast trending line just west of Golden agrees with the geometry of a previously recorded alignment of microearthquakes. Furthermore, the alignment seems to correspond to generally northwest-southeast trending fault geometries of the area. This all seems to suggest active displacement occurring along a fault in this region. The overall microseismicity level recorded by this array suggests a reccurrence interval of between 100 and 1000 years for an event similar to the M 6.6 that shook the region in 1888.

Figure 1 The final earthquake map. The color scale refers to topographical elevation in meters. The earthquakes are denoted by the red circles (smallest = M 0.0 to 0.5, next largest = M 0.5 to 1.0, next largest = M 1.0 to 1.5, largest = greater than M 1.5). The location errors are denoted by the ellipses centered on their respective earthquakes. The station locations are denoted by the stars.

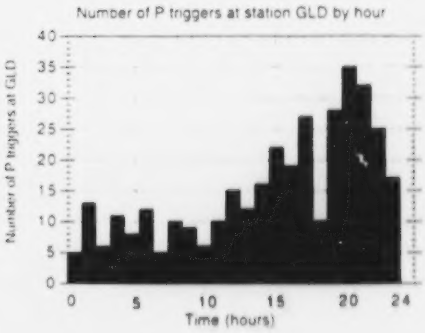

Figure 2. A histogram of the number of events vs. time of day for the USGS station in Golden. Note that the number of events recorded goes up during daytime hours. This indicates that "cultural noise", such as mine blasts, could be producing false seismic signals. The hours are displayed in GMT (subtract 6 hours to convert to MST).

Atmospheric Teleconnections and United States Regional Climates

Dana M. McCracken

Anthony J. Vega

This study attempts to understand the linkage between US precipitation and temperature regions and mean atmospheric flow anomalies represented by atmospheric teleconnection indices. Results indicate that mean zonal flow across North American relates to positive precipitation anomalies in many regions. The precipitation anomalies are especially strong during El Nino months when the moisture and energy flux from the tropics to the mid-latitudes increases. Relationships also exist between areas of mean atmospheric ridging (troughing) and positive (negative) regional temperature anomalies.

INTRODUCTION

The need to understand spatial and temporal variations of atmospheric related phenenomena has grown despite continued technological advances. This is especially evident at the regional-scale as phenomenon, both surface and atmospheric, are difficult to model, interpret, and link to larger-scale features. One method of linking surface parameter variations to generalized atmospheric flow is through correlations with atmospheric teleconnections. Atmospheric teleconnections are large-scale correlations fields in a variable (pressure or geopotential height) that represent standing long waves in the atmospheric flow. Wallace and Gutzler (1981) identified many such atmospheric teleconnections in the 700 mb geopotential height field. They also devised several simple indices to detect the presence and strength of the most important teleconnections in the Northern Hemisphere at a given time. Use of such indices for climate applications has grown tremendously in recent years (Leathers et al., 1991; Rogers and Rohli, 1991). However, many studies do not fully integrate aspects of many teleconnection indices to define links between the surface environment and the atmosphere. This study uses teleconnection indices determined to be most important to the climate of North America to further define the linkage between the atmosphere and United States regional precipitation and temperature variations.

DATA AND METHODS

The regionalization of US precipitation and temperature is fully described in Fiscus (1997). The derived climate regions and the associated climate anomaly time-series from Fiscus (1997) are used exclusively in this study. Surface data are composed of regionally clustered standardized precipitation and temperature anomalies calculated for annual and seasonal time-series.

For the teleconnection analysis, this study utilizes the Pacific-North American (PNA) teleconnection index, and the Southern Oscillation Index (SOI) to estimate generalized Northern Hemisphere atmospheric flow. Data were obtained from the Climate Analysis Center. The PNA time-series used here extends from 1947-1986, and the SOI time-series from 1895-1991. The indices were derived from either standardized geopotential heights (PNA) or standardized sea-level pressure variations (SOI). The teleconnection indices are tied to US regional surface parameters (precipitation and temperature) through Pearson correlation coefficients. Because the teleconnection indices have different record lengths, some bias may be introduced into the correlations analysis as higher degrees of freedom are associated with lower amounts of explained variance in significant correlations.

ANALYSIS

The PNA teleconnection is undoubtedly one of, if not the, most important teleconnection pattern with regard to the North American surface climate. This upper atmospheric pattern has centers of action near the North Pacific subtropical high, the Aleutian low, northwestern North America, and the Florida panhandle. The major characteristic of the PNA flow regime is a ridge, evident in the 700 mb geopotential height field, centered on the Rocky Mountains with adjacent long-wave troughs near the Aleutian and Florida action centers. Changes in the strength and amplitude of the PNA pattern are known to have significant impacts on North American temperature (Rogers and Rohli, 1991) and precipitation (Henderson and Vega, 1996). The pattern has been shown to be temporally persistent on a monthly (Barnston and Livezy, 1987) and intra-monthly (Vega et al., 1995) time-scale, in addition to being evident at various tropospheric levels. Wallace and Gutzler (1981) derived a simple index which estimates flow variations in association with the PNA teleconnection pattern. The index denotes meridional (amplified ridge-trough) long-wave flow through positive index values, zonal (deamplified) flow through near zero values, and reversed (meridional trough-ridge) flow through negative values.

Due to the discontinuous nature of precipitation, few significant relationships are found between the PNA index and the annual time-series. Only the Mid-West (PC1) and Southwest (PC9) regions show a direct relationship with the flow patterns. The weak correlations explain only a small amount of variance and are significant only at the 0.10 alpha level. However, the analysis indicates the relative importance of the long-wave flow regime on the surface climate as a negative correlation exists between the Mid-West region and the index. Zonal flow regimes are therefore responsible for positive precipitation anomalies in this area. Zonal flow ensures that mean wave cyclone trajectories pass over this region. Meridional flow places the mean cyclone trajectories too far to the south during the high positive PNA phase resulting in negative regional precipitation anomalies. Meridional flow associated with the revered phase of the PNA places the region under the influence of the mean upper-air ridge which also significantly reduces regional precipitation. Identifying physical causes associated with the positively associated Southwest region is more problematic. The correlation indicates that amplified longwave flow relates significantly to positive precipitation anomalies within the region. This relationship may extend from the dissipation of Pacific induced wave cyclones during positive PNA times. Zonal low places dissipating cyclones poleward of the region leading to negative precipitation anomalies.

Winter correlations fare much better than those of the annual time-series, validating many previous studies comparing the PNA to the cool season surface environment (Rogers and Rohli, 1991). Significant relationships are found between the index and the Mid-South (PC2), the Mid-West (PC3), the Northwest (PC5), the Upper Plains (PC7), and the Northern Rockies (PC9) precipitation regions. All of the significant correlations are negative indicating that zonal flow regimes, or reversed flow regimes, relate to enhanced precipitation in these areas. This is climatologically plausible as zonal flow is typically indicative of a poleward displaced mean jet, resulting in wave cyclone trajectories over the northern tier of climate regions in the west and the regions which traverse the upper Mississippi and Ohio River valleys in the east.

Of the four significant springtime regions, only the Upper Plains (PC7) shows a weak negative relationship. Positive relationships exist with the Southeast (PC3), the Southern Plains (PC8), and the Central Plains (PC9). This indicates the importance of wave cyclogenesis in the Colorado cyclogenetic region and the resulting trajectories. Positively amplified flow places the mean eastern trough in close proximity to all of the related regions except the upper plains (PC7) which lies poleward of the flow axis during these times. Studies have shown (Henderson and Vega, 1996) that the PNA is a reliable flow indicator during the warm season as it relates to the expansion/contraction of pressure cells in close proximity to the PNA action centers. This relationship is demonstrated by the positive correlations between the index and the Southeastern (PC1) and South Central (PC7) regions. The index is influenced by enhanced onshore flow and low level moisture advection associated with the North Atlantic Subtropical High (STH). Such flow induces low level instability in the southeastern US which enhances precipitation.

During the autumn season, the PNA index correlates negatively with the Mid-West (PC1), the Northwest (PC4), the Southern Plains (PC5), the Northeastern Plains (PC7), and the Northwestern Plains (PC8). Physical mechanisms responsible for such relationships are similar to the annual time-series as zonal flow significantly affects the northwestern tier regions due to a higher mean latitude of long-wave flow.

Surface temperature relationships are easily established with the PNA. Significant correlations agree with previous studies (Leathers et al., 1991) in the negative temperature departures exist in relation to mean troughing while positive relationships relate to prominent ridging. This is true of annual as well as seasonal relationships as many of the temperature regions correlate significantly with the index. The winter and autumn time-series relates especially well to index variations.

Many studies provide insight into the relationship between the SOI and the North American surface climate. Douglas and Englehart (1982) provide an indepth analysis of the links between US precipitation and the SOI, especially for Florida where the SOI explains approximately one half of Florida's precipitation variability. Further links have been established by Henderson and Vega (1996) for the southern US, Vega et al. (in press) for mid-tropospheric variations over the Gulf of Mexico related to extreme SOI phases, and US precipitation patterns and variability (Ropelewski and Halpert, 1989). Although many relationships are apparent, the physical link between atmospheric and SST variations in the equatorial Pacific and the North American surface climate remain ambiguous. Analysis of monthly geopotential height fields reveals a striking correlation between the negative (positive) phase of the SOI (El Nino) and the positive (negative) PNA pattern. It has been surmised that equatorial variations force the PNA into the highly amplified wave pattern through increases in tropic-to-mid-latitude energy and moisture. This is evident through a stronger and more persistent subtropical jet over the western and southern US which induces Gulf of Mexico cyclogenesis (Vega et al., in press) leading to positive precipitation anomalies in much of the US.

This study confirms the relationship between positive precipitation departures in much of the US and the negative phase of the SOI. On an annual basis, much of the central US (PCs 5-8) correlates significantly with the SOI. During the El Nino (La Nina) phase of the SOI, positive (negative) precipitation anomalies occur throughout these regions. The Southwest (PC9) region also negatively correlates to the SOI. This is due to increased cool season cyclogenesis off the Pacific Coast during El Nino times caused by an anomalous warm water pool which supports low level instability. This couples with upper level venting associated with the strengthened subtropical jet inducing Pacific cyclogenesis.

During the winter season, only three precipitation regions correlate negatively to the SOI; the Southeast (PC4), the Lower Plains (PC6) and the Southwest (PC8). During the winter season, the Southeast precipitation region is zonally more inclusive than during the annual time-series. The winter season region includes much of the South Central annual region, implying that much of the association between the Southeast and the SOI resides over the western portion of the region. The Southwest also correlates negatively to the SOI, signifying the link between the warm water anomalies in the southwestern Pacific and cyclogenesis near the west coast of the US. The impact of more frequent cyclogenesis carries through to the spring season as three precipitation regions correlate negatively to the SOI. All of the associated regions are located in the central to western US implying a significant impact from increases cyclogenetic frequency off the California coast.

During summer, two regions correlate significantly with the SOI, the Southeast (PC1) which is positively related and the Southwest (PC8) which is negatively related. The correlations are consistent with those found during other season. The autumn season depicts three regional relationships with the SOI. The Lower Plains (PC5), the Northeastern Plains (PC7), and the Southwest (PC9) are all negatively related. Physical links may be tied to increased frequencies of late season wave cyclones.

Regional surface temperature relationships (annual-autumn) show predominantly negative relationships to the SOI. Therefore, the physical relationship denotes positive (negative) temperature anomalies during the El Nino (La Nina) SOI phase. This physical link relates to the amplification of the mean longwave flow which produces greater temperature anomalies than during relatively steady zonal flow regimes.

CONCLUSIONS

This study attempts to relate previously derived precipitation and temperature regions to mean atmospheric flow anomalies represented by the Pacific-North American teleconnection pattern and the Southern Oscillation. Results indicate that mean zonal flow across North America relates to broadly defined precipitation increases. This is due to precipitation forcing along the greatest expanse of the conterminous US. During highly amplified flow regimes, precipitation forcing is confined to areas south and east of the deepened trough. Mean positive precipitation departures are also evident during El Nino events which relate well to increases in energy and moisture into the US. Temperature relationships are easily defined with areas near mean ridges recording positive anomalies while regions near mean troughs record negative anomalies.

Recent studies have shown that acid phosphatase (AP) may have the ability to suppress the production of reactive oxygen intermediates in host hemocytes leading to increased infection rates in the host. This study characterized the biochemical behavior of AP extracted from *Perkinsus marinus* to elucidate the functional role of AP within the host-parasite relationship. The effect of temperature, substrate concentration, pH and buffers, and inhibitors on AP activity was determined. The highest activity was observed at 50°C, and activity increased with increasing substrate concentrations. The buffer that displayed the greatest activity was 0.1M acetate buffer at pH 4.0. In comparison, the highest activity in a 0.5M citrate buffer was observed at pH 4.4, in 0.5M McIlvaine buffer at pH 2.8, and in Potassium Hydrogen Phthalate buffer at pH 4.0. Sodium fluoride was a potent inhibitor of acid phosphatase activity. Okadaic acid significantly reduced AP activity, and nodularin was a weak inhibitor at low concentrations. EDTA had no significant effect on AP activity. These results suggest that AP in *Perkinsus marinus* may be a type PP2B phosphatase. Additional study of the purified enzyme may confirm these results and lead to the development of chemotherapeutics.

INTRODUCTION

Phagocytosis and production of reactive oxygen intermediates (ROI) is a main defense mechanism in molluscs. The hemolymph of molluscs is known to be involved in internal defense against invading organisms. When nonself organisms or molecules invade or are experimentally introduced into gastropods or pelecypods they are usually phagocytosed or encapsulated (Cheng and Roderick 1974).

The process of phagocytosis is initiated by the recognition of foreign particles by hemocytes. When vertebrate macrophage membranes are stimulated by non self particles or organisms, stimulation of NADPH oxidase and activation of the hexose monophosphate pathway occurs. This is accompanied by the production of toxic reactive oxygen intermediates (ROI). These ROIs are microbicidal (Volety and Chu 1994).

There are numerous ways that an invading organism may evade the defense mechanisms of the host organism. Certain protozoan parasites employ mechanisms such as active entry into host cells, entry into host cells without triggering the respiratory burst, and suppression and/or inhibition of ROI production by phagocytes (Volety and Chu 1994). A proposed mechanism for the suppression of ROI production is the presence of acid phosphatase in the parasite cells. Acid phosphatase of the promastigote *Leishmania donovani* is capable of inhibiting the production of superoxide anions by human neutrophils (Remaley et al. 1984). This might indicate a contribution of acid phosphatase to the survival of the parasite by interfering with host oxygen-dependent killing mechanisms.

For many years, the eastern oyster *Crassostrea virginica* has been a victim of the protozoan parasite *Perkinsus marinus*. This study was conducted to characterize AP activity in an attempt to better understand its role in the parasite's virulence. Understanding the physiologic and physiopathologic properties of *Perkinsus marinus* acid phosphatase might allow better knowledge about the hemocyte-parasite relationship of *P. marinus* and *C. virginica* and the possible development of chemotherapuetics.

MATERIALS AND METHODS

Perkinsus marinus meronts were cultured in 12 well culture plates (N=6) according to Gauthier and Vasta (1993). A cell viability assay was performed using trypan blue dye exclusion method. Determination of cell protein was carried out according to Lowry et al. (1951). The acid phosphatase activity assays were performed according to Andersch and Szczypinski (1947).

Table 1. Parameters and description of assays performed

Parameters Tested	Assay Components
Buffer System	Acetate, Citrate, McIlvaine, and Potassium Hydrogen Phthalate buffers pH 2.4-6.0
Temperature	6 temperatures in the range of 10 to 70°C
Substrate Concentration (p-Nitrophenyl phosphatase)	7 dilutions ranging from 0.25 to 10 ppm
Inhibitors	Inhibitors tested were NaF, EDTA, Nodularin, and Okadaic Acid (0.00M control)

RESULTS

The results from each assay are shown in the figures below. The acid phosphatase activity of the pH, temperature, and substrate concentration assays are expressed as units per milliliter. The activities for the inhibitor assays are expressed as a percent of the control solution.

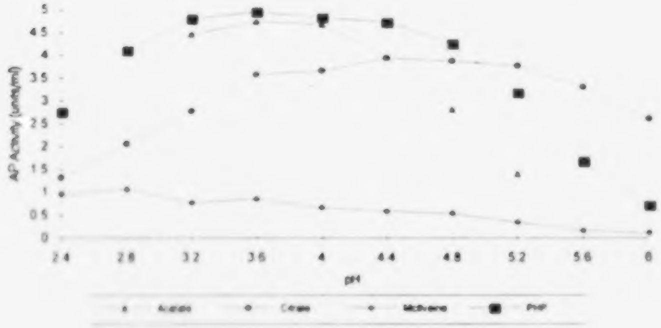

Figure 1. Effect of pH and buffer systems on AP activity of *Perkinsus marinus*

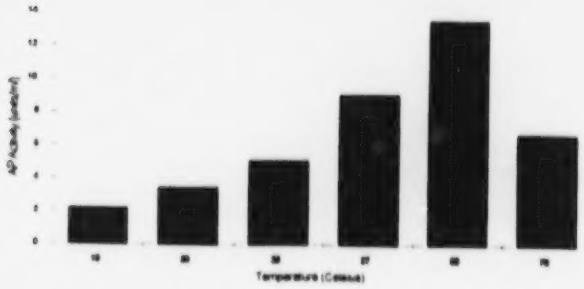

Figure 2. Effect of temperature on AP activity of *Perkinsus marinus*

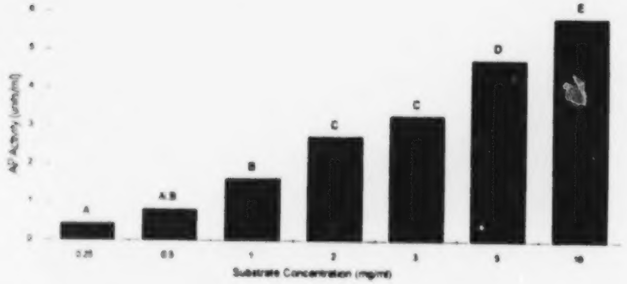

Figure 3. Effect of substrate concentration on AP activity of *Perkinsus marinus*

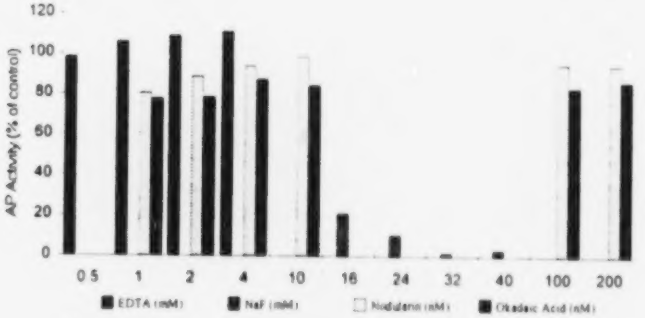

Figure 4. Effect of Inhibitors on AP activity of *Perkinsus marinus*

DISCUSSION AND CONCLUSIONS

The results from the temperature experiment are similar to the findings of Gottlieb and Dwyer (1981). They found that the optimal activity of membrane bound acid phosphatase of *Leishmania donovani* was 42°C. At higher temperatures, a decrease in lysosomal enzymes into the oyster serum has been observed (Chu and La Peyre 1993). With increased activity of acid phosphatase and decreased defense ability, the oyster may be more susceptible to infection at the higher temperatures. The decrease in activity at temperatures above 50°C may be explained by the denaturation of the enzyme.

The pH study yielded similar results of a study of membrane acid phosphatase conducted by Gottlieb and Dwyer (1981). The membrane phosphatase displayed an optimum at a pH of 5.0, while these tests showed an optimum between 3.6 and 4.8 for the three most effective buffers.

The rise in activity correlated with the rise in substrate concentration was expected. There was more substrate from which to liberate *p*-nitrophenol by the enzyme , so the higher concentrations produced higher activities. The inhibitor experiments will perhaps provide the best information for classification of the acid phosphatase.

Sodium fluoride was the only effective inhibitor of this acid phosphatase. All of the test treatment activities were significantly lower than the observed activity of the control. The addition of EDTA to extracellular acid phosphatase had no significant effect on the activity of the enzyme. EDTA is an inhibitor of enzymes which require the presence of divalent cations to be active. Since the phosphatase was not inhibited, its activity is probably not dependent on these cations.

Nodularin was only effective as an inhibitor at low concentrations. Nodularin is a potent inhibitor of PP1 and PP2A but did not effect the activity of extracellular acid phosphatase. Conversely, nodularin is a weak inhibitor of Ca^{+2}/calmouldin-dependent phosphatase PP2B. These reports are consistent with our results. Nodularin has been shown to be enzyme dependent and not substrate dependent, so there is no outside effect from the substrate used.

Okadaic acid has a specific and potent inhibitory activity against PP1 and PP2A (Honkanen et al. 1993). In our study, okadaic was a weak inhibitor of the phosphatase but still stronger than nodularin and EDTA inhibitors. Under experimental conditions reported by Honkanen et al. (1993), okadaic acid inhibits the activity of PP2A and PP3 more potently than PP1(order of potentcy PP2A>PP3>PP1).

According to the literature on protein inhibitors and our results, it seems that this acid phosphatase could be a member PP2B. Since nodularin weakly inhibited the acid phosphatase in these experiments, the extracellular phosphatase could be a member of PP2B. These are similar to the results obtained in this study which may lead to the conclusion that extracellular acid phosphatase from *P. marinus* may be a part of this class of proteins. Further studies of the purified enzyme are needed to verify these results.

ACKNOWLEDGEMENTS

This research is a result of an NSF internship. Funding for this study was made possible through a grant from NOAA, NMFS Oyster Disease Research Project. The author is an undergraduate student at Coastal Carolina University, Conway, SC 29526.

Faculty Advisors:

Horton H. Hobbs III and John B. Ritter

ABSTRACT

Microhabitat (i.e. velocity, depth, cover, and substrate) use by lotic fish assemblages was examined within a fourth-order reach of the Little Miami River, a state-protected scenic waterway originating in Clark County, Ohio. Microhabitat availability and channel structure were mapped for a 270 m study area and fish samples were collected within a stratified random sampling design, where the strata were general habitat classifications (i.e. pool, run, and riffle). Samples were collected from July through November 1996. Fourteen species of fishes were observed within a broad range of microhabitat conditions. The Northern Creek Chub *Semotilus atromaculatus atromaculatus* (Mitchill), Common White Sucker *Catostomus commersoni commersoni* (Lacepede), Ohio Stoneroller Minnow *Campostoma anomalum anomalum* (Rafinesque), and Greenside Darter *Etheostoma blennioides blennioides* (Rafinesque; all species authors from Trautman 1981) were the most abundant species. Analysis of microhabitat use data revealed few strong correlations. Mean depth values for all observed species were limited to a 0.38 to 0.70 m range. While fishes utilized a broad range of mean velocities (0.00 to 0.53 m/sec), within species variation in actual velocity confounded the effort to define significant correlations. Likewise, cover and substrate observations appeared random. The obscurity of these data may be due to extreme shifts in microhabitat availability that occurred during the sampling period (e.g. major flooding, followed by extended drought). However, the failure to determine useful microhabitat trends is most likely due to an insufficient number of samples.

INTRODUCTION

Habitat use by fishes within lotic systems of the eastern United States is a concern that has received much attention in recent years (Grossman and Freeman 1987; Bain et al. 1988; Leonard and Orth 1988; Reiser et al. 1989; Aadland 1993; Vadas and Orth 1993; Grossman et al. 1995). The high species diversity that is typically observed in these warmwater streams (relative to western coldwater streams), combined with the erratic and often times unpredictable nature of hydrologic events, makes it difficult to assess the well-being of native fish populations (Reiser et al. 1989; Langton et al. 1996). Fisheries personnel from all backgrounds should then benefit from sampling regimes that minimize the variation within and between habitat surveys (Reiser et al. 1989). However, such protocols often require extensive support. It therefore becomes important to maximize sampling efforts, as time, resources, and manpower are frequently the most limiting factors within stream surveys (Paller 1995; Peterson and Rabeni 1995).

In this study, microhabitat use by fish communities was examined within a headwater reach of the Little Miami River, Clark County, Ohio. Microhabitat (i.e., depth, velocity, cover, and substrate) was chosen for two reasons. First, microhabitat has frequently been cited as the most significant factor or variable in accounting for fish distribution patterns within warmwater streams of the eastern U.S. (Grossman and Freeman 1987; Bain et al. 1988; Leonard and Orth 1988; Freeman et al. 1990; Aadland 1993). Second, microhabitat is a relatively simple feature to quantify within low-order streams; cover and substrate do present problems when calibrating an appropriate scale for their quantification, but some microhabitat studies have found depth and velocity to account for the majority of microhabitat variance, with little variation attributed to cover and/or substrate (Aadland 1993). Following their collection, microhabitat data were evaluated in the hope of identifying useful trends.

STUDY AREA

Microhabitat data were collected within a fourth-order reach of the Little Miami River (Figure 1). This reach is 270 m in length, with a drainage area of 133.4 km^2. Local geology is characterized by fairly even topography, underlain primarily by limestones and dolomites (i.e., Springfield and Cedarville Dolomites) of the Niagara group (Brown 1960), which are blanketed by large deposits of glacial till.

Land use within the area is predominantly agricultural, based largely upon the harvesting of corn and soybeans. Extensive channelization (particularly straightening) of the channel bed occurred between 1952 and 1958, when a joint effort between the Ohio Department of Natural Resources (Division of Wildlife) and local land owners was instituted to regulate discharge (Brown 1960). However, while optimizing discharge controls, such efforts typically result in the loss of habitat diversity and a consequent reduction in species diversity (Simpson et al. 1982).

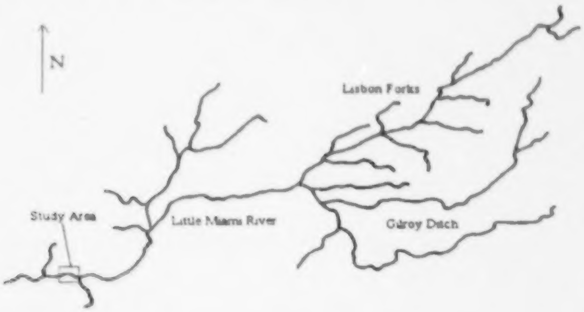

Figure 1. Map of the Upper Little Miami watershed (from U.S.G.S., Springfield, OH; 1:100,000).

METHODS

Surveying of the study area was completed during July 1996, using a modified deflection angle traverse method (Murphy and Willis 1996) to create a scale base map. This map featured habitat classifications (i.e., pools, runs, and riffles) and distinct structural components (e.g., fallen trees, undercut banks, gravel bars, etc.). Generalistic pool, run, and riffle designations were assigned according to Ritter et al. (1995), where pools were relatively deep, slow moving areas, runs were shallow, fast moving zones within the pool-riffle transition, and riffles were similar to runs but characterized by turbulent surface flows. A longitudinal profile was also established for the entire study area.

A stratified random sampling design was used to orchestrate field work (Bovee 1986; Murphy and Willis 1996), with pools, runs, and riffles as the strata. Sampling effort was partitioned among the three habitat classes according to their dominance within the system, while sampling within each strata was randomized.

Fishes were sampled with a Coffelt Mark-10 backpack electroshocker. All samples were set at 300V output, DC, using the Coffelt CPS wave signature and the diamond-ring electrode configuration. Shock intervals ranged from 38-135 seconds, depending primarily upon the complexity of the habitat being sampled; excessive cover generally mandated longer shock intervals. Shocked fishes were collected with dip nets, identified, and measured.

Microhabitat was recorded after each shocking event. Several depth readings were taken at each sample location using stadia rods and meter sticks, with their mean value representing available depth. Velocity readings were taken with a Global Water current meter and averaged for each sample. Substrate was estimated using a modified Brusven index (Bovee 1982) based upon dominant materials (fines, sand, small gravel, medium gravel, large gravel, small cobble, large cobble, boulder), and a relative roughness scale (very rough - very smooth). These two categories or "variables" were then converted to a single substrate value for each observation; dominant material and relative roughness each acted as a treatment in this conversion, creating "substrate scores," ranging from 0-11, based upon the theme: "How difficult is it to walk over this particular substrate?" (A score of 0 indicates a sandy, homogenous substrate. A score of 11 indicates a rocky stream bed, consisting of large particles mixed with smaller ones; a prime opportunity to twist a few ankles.) Cover was classified using the system described by Bovee (1982) and a relative shade designation (total shade - no shade). Cover was also converted to a thematic scale, where the size of local objects, the presence of root wads and/or undercut banks, and overhanging vegetation, along with relative shade, acted as the four treatments. This produced "cover scores," ranging from 0-15, where the highest scores represented the "most complete cover."

RESULTS & DISCUSSION

One-hundred seventy-four fish were collected during the 5 month study period, representing 14 species. The Northern Creek Chub *Semotilus atromaculatus atromaculatus* and Ohio Stoneroller Minnow *Campostoma anomalum anomalum* were the two most abundant species, with 58 and 53 specimens observed, respectively. Extreme standard deviations and coefficients of variation reflect diffuse microhabitat use trends (Table 1). Only depth use by the Northern Creek Chub and the Ohio Stoneroller Minnow indicated strong central tendencies.

A broad range of discharge events took place between June and November 1996. Excessive rainfall led to extreme flooding during most of June, with discharge reaching stages greater than 6 times the median daily streamflow for the past 41 years. However, severe drought throughout August and early September 1996 produced either an intermittent or stranded condition within many upper reaches of the Little Miami River. Therefore, a consequent loss of habitat diversity and/or availability may have occurred (Simpson et al. 1982; Bain et al. 1988). Discharge values observed during sampling events ranged from 0.19 to 0.41 m^3/sec.

Although microhabitat use trends were not readily apparent, a collective look at all species does suggest what might be a limiting microhabitat factor: mean depths emphasize the possibility of a minimum depth requirement for normal species distributions. The shallowest mean depths were occupied by Greenside and Rainbow Darters (which are both bottom-dwelling species), at 0.38 m. It may be that depths less than approximately 0.38 m are incapable of supporting healthy fish assemblages, in which case reduced or intermittent flows would have serious detrimental effects upon native fish populations (Simpson et al. 1982; Bain et al. 1988).

A number of biases should be addressed before reaching any definitive conclusions. Foremost is the assumption that fish communities are utilizing available habitat in a non-random fashion. Many of the species observed within the Little Miami River appear to be habitat generalists, using a broad range of depths and velocities. Indeed, the total absence of habitat specialists adds considerably to the task of modeling microhabitat use patterns (Fausch et al. 1988; Leonard and Orth 1988).

Sampling techniques undoubtedly introduced some bias to the results. Some fishes did have an opportunity to escape the field of the electroshocker before undergoing electrotaxis and/or narcosis. Likewise, habitats with high population densities often produced more specimens than could be netted by a three-man crew. Therefore, some fish were seen to "passively" escape capture (as they drifted downstream). Also, substrate and cover designations were largely subjective; while depth and velocity were measured quantitatively, substrate and cover were recorded using qualitative descriptions, the validity of which depended upon the opinion and experience of the recorder. Such methods are typically cited as being sufficient, as their purpose is not so much an accurate description as the noting of differences between a series of habitats (Wang et al. 1996). However, they remain a potential source of sampling error.

The fact that the data presented here do not define discrete microhabitat trends does not necessarily imply that such trends are non-existent with the Upper Little Miami River. On the other hand, it is entirely possible that microhabitat is not a dominant factor in regulating local fish populations. Such dependance may be counterproductive within highly variable, relatively unstable reaches like the one presented here; the loss of habitat diversity imposed by previous channelization activities (Brown 1960), combined with the severe flooding and drought cycles that are so typical of small, low-order streams (Ritter et al. 1995), could have created a condition within the Little Miami headwaters where microhabitat dependant species would be at a considerable disadvantage.

As the Upper Little Miami continues its return to a more natural, sinuous condition, new microhabitats will be created while older ones are simultaneously lost. The classic pool-run-riffle sequence is not well established within the study reach examined here. However, pool, run,

and riffle habitats are unquestionably present, though arranged in a somewhat "haphazard" fashion. In other words, the headwaters of the Little Miami River are not currently in a state of equilibrium. Ultimately, if anthropogenic disturbances do not prevent them from doing so, these reaches will return to an equilibrium condition. But until then, erosional and depositional cycles will continue to occur in an erratic fashion (Ritter et al. 1995), imposing considerable stresses upon microhabitat sensitive species. It therefore becomes imperative that such species be identified, as their diminishment will inevitably degrade the quality of the entire lotic system (Aadland 1993).

ACKNOWLEDGEMENTS

This project was made possible by the efforts of a supportive and insightful faculty, as well as a number of patient, reliable peers. Many thanks to project advisors Dr. Horton H. Hobbs III and Dr. John B. Ritter. I am also indebted to Dr. Douglas M. Andrews, who assisted me in establishing the sampling design for this study. A very special thanks goes out to Seth Aigner, Lee Ott, Craig Faulhaber, Christopher Murray, Sharon Frey, and Megan Porter; their willingness to accompany me in the field for what often seemed like unreasonable hours really made this project a success. Finally, I would like to acknowledge the Wittenberg University Faculty Research Fund Board, which provided the necessary financial support.

Water Chemistry Habitat Assessment in Eastern Tiger Salamander Ponds

Sara E. Wirtz

Department of Chemistry
James Madison University
800 South Main Street
Harrisonburg, VA 22807

Faculty Adviser:

Dr. Daniel M. Downey

Eastern Tiger Salamanders (*Ambystoma tigrinum tigrinum*) inhabit only two known locations in Virginia. One of these locations is in an area known as Maple Flats, a unique 55 square mile area of George Washington National Forest that includes nearly two dozen sinkhole pond depressions. A team of scientists from various disciplines has been assembled to study this region to estimate the range, habitat, and status of the tiger salamanders. Previous studies of streams and lakes in this area indicate a reduction of biomass of trout and other aquatic species due to anthropogenic acid deposition (acid rain). To assess the effects of acid rain on the salamander pond water, samples were collected monthly. Parameters monitored included pH, acid neutralizing capacity (ANC), base cation concentrations and strong acid anion concentrations. The water samples revealed a pH range of 4.3 to 6.6 and an ANC range of -69 to 44. The results of this study will be used to help U.S. Forest officials manage the habitat for this state listed endangered species.

BACKGROUND

The Maple Flats ponds complex extends over a 55 square mile area along the western foothills of the Blue Ridge Mountains near Stuarts Draft, Virginia (Latitude: 38° 58' 30" Longitude: 79° 59' 00"). It is the largest assemblage of sinkhole ponds in Virginia's Shenandoah Valley and has been referred to as one of the most significant botanical areas in the Mid-Atlantic region (Hayslett & Smith, 1994). The area encompasses more than two dozen sinkhole ponds and contains currently undisturbed natural communities in the ponds and the associated woodland environment.

The sinkhole complex lies on a densely forested alluvial plain which extends in an arc fan approximately three miles from the base of the Blue Ridge Mountains. The fan is about 100 feet thick and is primarily composed of Antietam Formation quartzite sandstone, which is a low solubility, acidic rock. Over thousands of years, pockets formed in the carbonate bearing rock formations of the dolomitic bedrock that lies under the alluvium. The sinkhole ponds resulted from the collapse of these pockets to create shallow depressions in the alluvium; typically 3-10 feet maximum depth with surface areas of 0.5-5 acres.

This dynamic complex ecosystem has suffered greatly from the effects of human impact. The most significant human influence was the manganese and iron mining that occurred in the late nineteenth and early twentieth centuries. Since the 1950s, there have been several timber sales and clear cuttings. It is reported that during these timber management activities, "some buffer protection" was given to the sinkhole ponds (Hunt, 1991). The roads constructed for the timber sales are closed now, but modern disturbances, including hunting, fishing, camping, illegal ATV activity, littering, dumping, and encroaching housing developments, continue to adversely affect the area.

In 1982, the USDA stated that the Forest Service must treat all severely neglected areas in the National Forest by the year 2000 (Bracy, 1982). To meet this regulation, a Restoration Program was initiated for the Maple Flats region. In order to evaluate possible treatment alternatives, a study was conducted to identify possible rare or endangered species in the complex, and many were found, including twenty-six species of plants and seven animal species (Hayslett & Smith, 1994). In June 1987, eastern tiger salamander larvae were discovered in several sinkhole ponds at Maple Flats (Buhlman, 1987). On October 1, 1987, the tiger salamander was officially listed as endangered by the Virginia Department of Natural Heritage (Mitchell, 1991). Maple Flats is one of only two confirmed locations in Virginia inhabited by eastern tiger salamanders.

EASTERN TIGER SALAMANDERS

Eastern tiger salamanders are one of the world's largest land dwelling salamanders. An adult can reach a total length of 254 mm, of which about half is its tail. It is generally dull black or brown with irregularly spaced yellow to olive dorsal blotches which extend from the snout to the tip of the tail. Although there is no difference in total body length between males and females, males show a proportionally longer tail (Terwilliger, 1991). The toes of the eastern tiger salamander are uniquely depressed and pointed. This serves as a distinguishing characteristic from all other members of its family which have round toes. Adult salamanders live in burrows near shallow ponds generally in pine stands.

Adults migrate to breeding sites nocturnally in the late winter. Clutches of about 350 eggs are laid in masses of 35-75 each and are attached to submerged twigs and grass. The eggs hatch in about 30 days, and larvae remain in the ponds about four months until they reach an average 12.5 mm long. Major threats to the tiger salamander population include unpredictable water levels in ponds, fish stocking, logging, and acid rain deposition. In amphibians, low pH adversely affects sperm motility, development time to hatchling body size, hatchling survival, and larval growth rate (Whiteman, et al., 1995). The most critical period is between January and July each year.

WATER CHEMISTRY

In and effort to preserve the tiger salamander as well as the unique ecosystem of Maple Flats, a team of scientists from various disciplines was assembled to study the region. This research group was asked to collect and analyze samples from twelve representative ponds monthly for one year beginning in October 1995. Water chemistry analyses were performed to (1) find the principle solute concentrations in the ponds and observe any variations throughout the year, (2) determine the anthropogenic input to the ponds, (3) assess the impact of the water composition on the tiger salamander populations and (4) relate the water chemistry to soils and bedrock geology.

The following parameters were analyzed in the pond water samples. Initially, pH was measured to establish the acidity of each sample. Then the acid neutralizing capacity (ANC) was determined to establish the degree of buffering ability of the water. The following equation defines the ANC:

$$\text{ANC } (\mu\text{eq/L}) = [\text{Ca}^{2+}] + [\text{Mg}^{2+}] + [\text{Na}^{+}] + [\text{K}^{+}] - [\text{Cl}^{-}] - [\text{NO}_3^{-}] - [\text{SO}_4^{2-}] \qquad (1)$$

Zero and negative ANC values indicate an acidic sample with no buffering capacity. Chloride, nitrate, and sulfate were the only strong acid anions found in the water. Low levels of chloride are naturally present in the pond water, but may increase due to road salt, farm run off, or other human activities. Nitrate levels are usually near zero, but higher concentrations may be found in areas with large amounts of animal excrement or fertilizer. Sulfate is the principle acid anion of acid rain. High sulfate concentrations are often found in acidic samples. Sodium, potassium, magnesium, and calcium concentrations were measured to relate base cationic content to the solubility of the rock formations that influence the source of the water sample. Low concentrations of aluminum occur in natural waters. At low pH, minerals containing aluminum are solubilized which cause levels to reach toxic proportions. In addition to the pH, ANC, base cations, and strong acid anions, the temperature and depth of each pond were measured monthly.

RESULTS

All of the sinkhole ponds have a low pH; average values do not exceed pH 6 (Table 1). Water in equilibrium with CO_2 in the atmosphere has a pH ~ 5.6 (Schindler, 1988). A small amount of natural sulfuric and nitric acid lowers this value to pH 5.0 (Charlson & Redke, 1982). The Shenandoah Valley receives an average annual rainfall of 37-42 inches (Bracy, 1982), with an average pH of 4.2 (NADP, 1987), which is about ten times more acidic than unpolluted rainwater. Bicarbonate, HCO_3^-, is the major acid neutralizing ion available in natural waters. It is released when minerals such as limestone, $CaCO_3$, react with dissolved CO_2 and water.

$$CaCO_3 + CO_2 + H_2O \longrightarrow Ca + HCO_3^- \qquad (2)$$

BEST COPY AVAILABLE

A combination of low ANC and a high amounts of acid from precipitation depresses pH. The lowest annual values for ANC and pH were found primarily in winter and spring. This occurred concurrent with the hatching of tiger salamander larvae, which is a particularly sensitive stage in the salamander's life cycle.

Figures 1 and 2 graphically depict monthly pH and ANC values for three ponds that represent the general groupings existing in the Maple Flats region. Pond 2 is a member of a group that generally shows positive ANC values and rarely pH values below 5.0. Pond 18 is a member of a group whose ponds seldom show positive ANC values and usually have pH values below 5.0. Pond 17 is a member of a group that experiences a wide fluctuation in pH and ANC. Please note that Pond 2 and Pond 18 were dry in July of 1996, and Pond 2 was also dry in August of the same year. Although lines are connected on the graphs, this is not necessarily representative of true values for these months. Water levels were low in Pond 17 during these months as well. This led to increased concentrations of all ionic species which explains the peaks observed for these months in the figures. Adult tiger salamanders and larvae have been found in ponds 2, 12, 13 and 17.

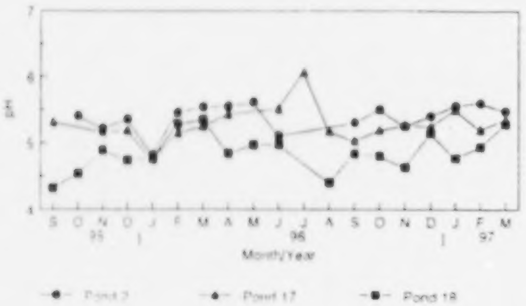

Figure 1. Representative pH Values for Maple Flats Ponds 2, 17 and 18

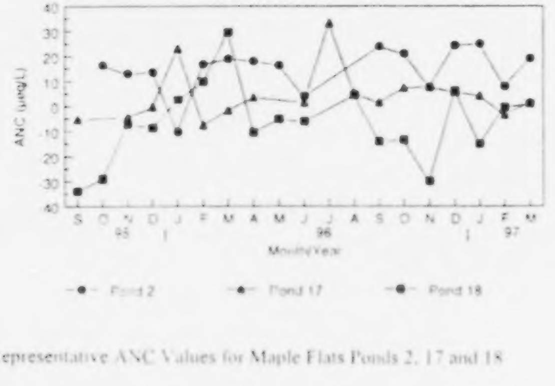

Figure 2. Representative ANC Values for Maple Flats Ponds 2, 17 and 18

The base cations, sodium, potassium, magnesium, and calcium, are so named because they provide a positive influence on ANC (Equation 1). The presence of these ions in water generally results from dissolution of minerals in the surrounding soils and bedrock geology. Low concentrations found for these metals provide strong evidence that the water in these ponds generally has experienced a short geological history. Special attention was paid to Ca^{2+}, which is essential to respiration and ionic balance in gilled organisms. The majority of the ponds have very low Ca^{2+} concentrations (Table 1).

Table 1: Average Values of Parameters Monitored from 9/95 to 2/97

Pond	pH	ANC	Na^+	K^+	Mg^{2+}	Ca^{2+}	Cl^-	NO_3^-	SO_4^{2-}	Al^{3+}	Ca^{2+}/H^+

Some concern has been raised about the ratio of calcium ion to hydronium ion in acidic surface waters. When pH decreases along with the concentration of Ca^{2+}, reduction in biomass of aquatic species occurs. Typically, a ratio of six or greater is considered acceptable. The average values of Ca^{2+}/H^+ ratio rarely exceed six, with the exception of the man-made ponds, 70 and 90 (Table 1). Figure 3 is a graphic representation of monthly Ca^{2+}/H^+ ratios for ponds 2, 17, and 18. The elevated Pond 17 value in July 1996 can again be explained by low water levels increasing the ionic concentration.

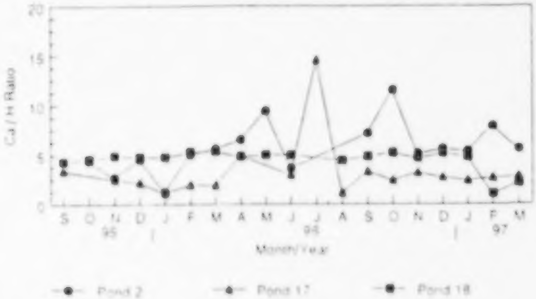

Figure 3: Representative Ca/H Values for Maple Flats Ponds 2, 17 and 18

The strong acid anions, chloride, nitrate, and sulfate, have negative effects on the ANC (Equation 1). Chloride is naturally present in small amounts proportional to the solubilization of minerals in the substrate around the ponds. Small chloride concentrations are further evidence of lack of mineral solute content in the water. Nitrate is derived from acid rain. In an area that receives approximately 40 inches of 4.2 pH precipitation annually, one might anticipate high concentrations of nitrate in the sinkhole pond water. Contrary to this expectation, nitrate levels are low due to its consumption by growing plants. Concentrations of nitrate are high only after storm events or snow melts causing significant run-off. Sulfate is the principle anion of acid rain. The ponds at Maple Flats typically have sulfate levels less than half of that of streams in the Blue Ridge region (Webb, et al., 1989). This suggests a high degree of sulfate retention in the soils surrounding the ponds.

Aluminum levels are inversely proportional to pH. Although aluminum is fairly prevalent in the earth's crust, it is generally insoluble at a neutral pH. When pH levels decrease, aluminum is solubilized and is extremely toxic to gilled aquatic life. The Maple Flats ponds rarely approach the tolerance limit of most aquatic species to aluminum (150 ppb) because the water is not actually in contact with the minerals long enough to release significant amounts of

BEST COPY AVAILABLE

solubilized aluminum, and organic compounds in the ponds complex aluminum and remove it from the water. Thus, toxic levels of aluminum in the pond water are not an immediate threat to the lives of the tiger salamanders.

CONCLUSION

The set of water chemistry values amassed by this research group will be used as a baseline with which changing parameters in the ponds can be compared. Considering the acidity and amount of rainfall which the Shenandoah Valley receives, as well as the low solubility of the surrounding geology, thus a lack of buffering in the ponds, the water chemistry of the Maple Flats ponds will inevitably degrade until they can no longer support aquatic life. Throughout the investigation of the Maple Flats ponds complex, much of the sulfate and nitrate from acid precipitation was retained in the watershed. In the future, the watershed will reach a saturation point at which anions will no longer be retained. Consequently, the pH of the ponds will fall drastically. The end result will be the deaths of all gilled aquatic species living in the ponds.

Amassing further knowledge about the sinkhole ponds and the Maple Flats region will enable the Forest Service to detect and counteract threatening conditions in the area. With only the monthly samplings, the influence of episodic storm events has not yet been deduced. The monthly samplings are now being supplemented by daily sampling at two specific ponds, one is known to support a tiger salamander colony, and the other does not. This will provide information regarding the effects of short term storm events on the ponds. In the future, it may be helpful to have an estimate of tiger salamander biomass associated with each pond inhabited by a salamander population. A correlation could then be drawn between the water chemistry data and the specific effect on the salamander population.

ACKNOWLEDGEMENTS

The author wishes to express her appreciation to the United States Forest Service and the James Madison University Chemistry Department for their funding and support.

The Derivation of United States Temperature and Precipitation Regions

Donna M. Fiscus

Faculty Advisor:

Anthony J. Vega

The goal of this study is to precisely define precipitation and temperature regions for the conterminous United States. A secondary goal is the identification of long-term regional trends in the climatic variables to determine regional climate change. Results indicate the derivation of plausible climate regions for both atmospheric parameters. Long-term regional trends were identified on an annual and seasonal basis. The most notable long-term changes relate to significant increases in precipitation across the US, especially during autumn and a significant increase in Southwestern US temperature.

INTRODUCTION

Recent climatological research has focused on automated classification techniques to provide spatial and temporal records of complex data arrays (Yarnal, 1993). Many of these techniques involve eigenvector analysis to determine primary surface patterns (Henderson and Vega, 1996) or dominant modes of atmospheric variation (Wallace and Gutzler, 1981). Current literature is replete with traditional eigenvector techniques and applications for classification (White et al., 1991), alternative classification methods such as harmonic analysis (Finkelstein and Truppi, 1991) and correlation techniques (Sumner, 1983). No matter the technique employed, climate classifications and regionalizations remain vital to a proper understanding of climate variability and its influence upon the surface environment (Yarnal, 1993).

Of the many eigenvector techniques, the most prevalent with regard to climatology is Principal Components Analysis (PCA). This is largely due to the simplicity and reliability of the procedure. Karl and Koscielny (1982) use rotated PCA to identify drought regions within the conterminous United States. Walsh et al. (1982) use a similar methodology to determine precipitation regions in the United States. Both studies incorporate statewide averages and select station data interpolated to a grid to derive regions. While such methods are common, the resulting regional demarcations are highly generalized and somewhat spatially incomplete.

This analysis seeks to precisely define precipitation and temperature regions for the conterminous United States. A secondary goal is to identify trends and significant patterns in the regional time-series to determine regional climate change. Ultimately, the goal is to enhance understanding of the regional response to large-scale climate fluctuations.

DATA AND METHODOLOGY

Mean monthly climate division precipitation and temperature totals are used for the contiguous United States. Monthly totals are used in their entirety for the annual analysis and grouped into standard meteorological seasons (winter=DJF) for the seasonal analysis. Data were extracted for all 344 United States climate divisions for the time period 1895-1991. Data were obtained from the National Climatic Information Disc Volume 1.

Climate division data are intended to represent relatively homogenous precipitation and temperature regions. In actuality, huge disparities exist in the number and size of the divisions within each state. PCA is used to effectively reduce the 344 climate division in addition to identifying physical homogeneity. Climate division data is highly desirable for the statistical techniques used as the data are aerially weighted and corrected for bias.

Data were standardized by month (mean=0; standard deviation=1) and merged into annual and seasonal arrays. PCA using a Pearson correlation matrix was used to isolate discrete regions of covariation. Varimax rotation techniques were employed to better determine the resulting solutions. Component retention was determined through a combination of the Kaiser-Guttman eigenvalue 1 criterion and a scree plot (Henderson and Vega, 1996). Component loadings were plotted to determine the spatial resolution of the eigenvectors utilizing a 0.45 eigenvector isoline cutoff for the precipitation variable and a 0.5 cutoff for the temperature variable. This procedure was followed in order to precisely define the associated regions with little transitory overlap. Once the final regions were produced spatially, a time-series of the precipitation and temperature anomalies was created to temporally isolate distinct regions of a particular phenomenon. A clustering procedure was used which combines the actual precipitation and temperature anomalies for each climate division included within a particular region.

ANALYSIS

For the precipitation variable, a total of nine components were retained for every season except summer, in which eight components were held for rotation. The unrotated components explain between 53 and 70% of the total variance in the annual-autumn time-series. For temperature, five principal components were retained for rotation with regard to the annual, spring, and autumn analysis, four for the winter analysis, and seven for summer. The total explained variance accounted for in the unrotated components varied between 84 and 88%. Loadings representing the spatial configuration of the components for all annual and seasonal precipitation and temperature regions are presented in Figure 1. It is apparent that the resulting precipitation regions are less cohesive than those for temperature. This is to be expected due to temporal and spatial discontinuities associated with the precipitation variable (Babin, 1995). Of special note are the climate divisions which did not correlate with any of the resulting precipitation regions (hatched areas). It is suspected that these areas are truly transitional.

The most striking feature associated with the precipitation analysis is the alignment of the eastern regions with known extratropical cyclone paths as identified by Zishka and Smith (1980). Such an alignment is evident in recent literature (Karl and Koscielny, 1982; Walsh et al., 1982) suggesting that migratory baroclinic wave forcing is the dominant precipitation generating mechanism for the eastern portion of the US, especially during the cool season.

Each regions anomaly time-series was tested for trend by correlating the derived precipitation anomaly by year. Results indicate many significant trends. PC's 1 through 6 of the annual time-series all display significant (alpha=0.05) increases in precipitation through time. Of the six regions, five (PC's 1-3, 5 and 6) display qualitatively substantial increases in variability. The shift in variability is important as this may cause considerable environmental stress in addition to biasing the linear regression procedure used to denote long-term change.

On a seasonal basis, long-term change is less apparent. For the winter season, only one region displays a significant trend through time, the Northwestern Plains (PC9). Here a significant decrease in precipitation occurred. For the spring season, three regions show significant increases in precipitation over the study period (PC1 at alpha=0.10). For the summer season, only one regional time-series displays a significant change through time, PC5. This component which represents the Northwest shows a significant increase in precipitation but displays a fairly constant level of variability throughout the time-series. The significant increases during the autumn season dominate the seasonal analysis as every region except PC4 and PC8 display significant trends. Further, surprisingly constant variability is evident in all of the regions with significant trend. This finding suggests that changes apparent during the autumn season are driving significant changes evident in the annual analysis as no other season displays trends which consistently match those of the annual time-series.

The derived temperature regions differ from those for precipitation in that they are primarily zonally symmetric and fewer in number, ranging from four winter regions to seven in summer. Complete spatial resolution is accomplished through the eigenvector procedure stemming from the continuous nature of the temperature parameter. An examination of the interannual temperature variability reveals more variability than precipitation. This is likely tied to the inherent colinearity of the temperature parameter in addition to the continuous link to atmospheric flow variations. Trend analysis reveals few significant annual or seasonal trends. The only significant trend in the annual record occurs in the Southwest (PC5). Here, a significant temperature increase is evident. The statistic

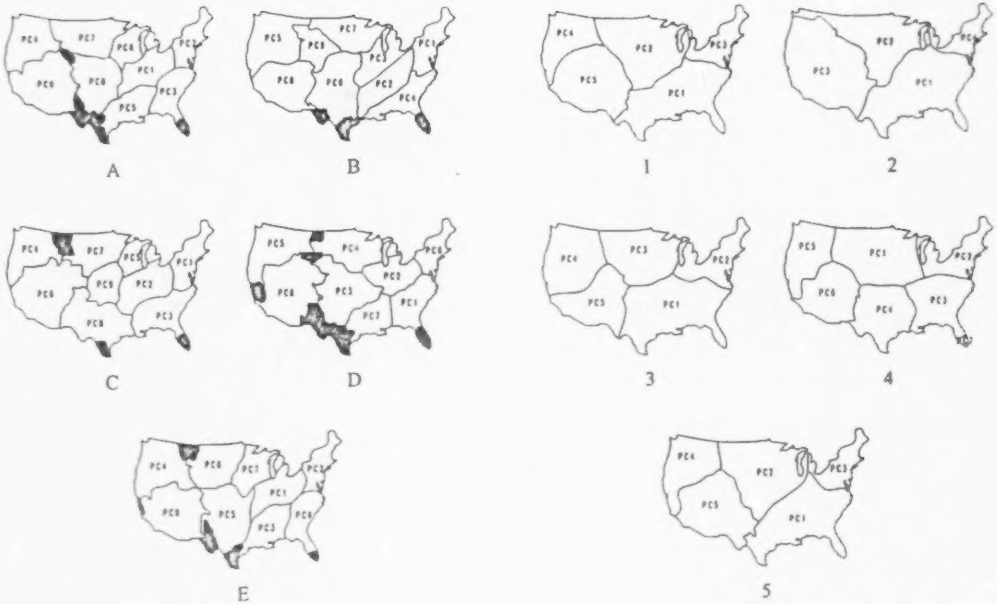

Figure 1. United States Annual - Autumn Precipitation (A - E) and Temperature (1 - 5) Regions.

may be biased by the extreme variability apparent from the early teens into the late 1930s. This is revealed in the qualitatively significant drop in variability across the study period. The time-series for this region, as well as many others, displays a somewhat cyclical pattern as early record cooling is followed by a high degree of warmth culminating in the late 1950s when a cool period ensued until the early 1980s followed by subsequent warming. The cooling which occurred following the late 1950s is likely due to the change in longwave flow amplitude documented by Leathers et al. (1991).

Statistical analysis of the winter season temperature anomalies reveals no significant long-term trends. The spring season analysis shows that the Upper Plains (PC3) significantly warmed over the temporal period. Although variability remains rather constant through the study period, a recent explosion of high variability and mainly positive anomalies dominates the temporal record. The summer period is interesting in that four of the associated regions show significant trends. All of these regions show significance at the 0.50 alpha level except the Southwest (PC6; alpha=0.10). The Upper Plains (PC1), the Southwest (PC6), and South Florida (PC7) all display a warming trend while the Southeast (PC3) indicates significant cooling over the study period. Substantial changes in variability are notable in association with the Upper Plains and Southwest (PC6) which depict decreasing variability through time, matching the annual record. The autumn time-series analysis reveals no significant temporal trends.

CONCLUSIONS

This study attempted to regionalize precipitation and temperature for the conterminous United States. PCA was used to effectively reduce climate division data and create physically based homogeneous climate regions. Results and comparisons with relevant literature indicate that the annual-autumn regions are climatologically plausible for both parameters. Further, significant long-term trends were identified in the associated regional time-series. For precipitation, substantial increases in precipitation were evident. It is believed that significant precipitation changes evident during autumn are in part responsible for the annual changes. For temperature, fewer annual and seasonal changes were noted. However, substantial increases through time are apparent especially with regard to the Southwestern US.

Analysis of satellite Advanced Very High Resolution Radiometer (AVHRR) data can be complicated by the presence of clouds. Therefore, it is necessary to effectively remove cloud contaminated pixels from an image before it can be used to calculate Normalized Difference Vegetation Index (NDVI). This study focuses on the use of a threshold technique to cloud mask the satellite images. A separate aspect of this study also looked briefly at the effects of two compositing techniques. It was concluded that the compositing process for both methods was highly affected by the quality of the cloud mask that was previously performed.

INTRODUCTION

The Advanced Very High Resolution Radiometer (AVHRR) on board the NOAA 14 satellite can be used for determination of vegetation indices. This satellite is in a polar orbit that allows it to complete one orbit in 101 minutes [3]. The orbit of NOAA 14 is heliosynchronous, which causes the satellite to pass over a spot on the earth at a slightly different time each day [3].

The AVHRR on NOAA 14 measures the visible radiation ($.58$ - $.68\mu m$) on channel one, near infrared ($.725$ - $1.10\mu m$ and 3.55 - $3.93\mu m$) on channels two and three respectively, and the infrared radiation (10.3 - $11.3\mu m$ and 11.3 - $12.5\mu m$) on channels four and five respectively.

By using the information in channels one and two, and the following formula, the Normalized Difference Vegetation Index (NDVI) can be calculated.

$$NDVI = (ch2 - ch1) / (ch1 + ch2) \qquad (1)$$

This index gives scientists a measure of how much chlorophyll is in the area of interest (AOI).

However, analysis of the AVHRR data can be complicated by the presence of clouds. Large thick clouds can completely obscure the ground cover, while smaller thinner clouds more subtly alter the radiation emitted over a given area of land. In fact, cloud cover can appreciably lower NDVI values [5]. Therefore, it is necessary to effectively remove cloud contaminated pixels before the data can be used to calculate NDVI. This study used a number of different thresholding methods to cloud mask the satellite images. After the data was cloud masked, composite NDVI images were created. This process will also be discussed.

DATA ACQUISITION

The AVHRR data was directly downloaded from NOAA 14 using Smartrack 1.2dQ. This software received the data as a High Resolution Picture Transmission (HRPT), and then put the data through level 1b processing, which appends calibration data and earth location to the data [4].

The data was then transferred to ERDAS Imagine 8.2, which resampled the data so that it only contained the AOI. In this case the AOI was the Southern Great Plains Cloud and Radiation Testbed (SGPCART) site. Then an initial cloud contaminated NDVI image was created. The images used in the cloud masking study were from January 1996 to the present.

CLOUD MASKING

Several different thresholding methods were applied to the data to eliminate the effect of clouds. These techniques include a channel four test, a channel one test, a negative NDVI test, and a channel four NDVI test. The tests were run in conjunction with each other and separately to determine their validity. For all of the tests, data points that failed the test were assigned a value of zero, elsewhere the NDVI values were reported.

The channel four test eliminated clouds based on their temperature. Since clouds are higher in the atmosphere than the land under them, they are generally colder [1], so this test removed everything below a certain temperature or threshold value. The threshold value had to be determined by individual examination of each image. Threshold values around 100 were used for summer images, and values around 85 were used during the winter.

The channel one test eliminated clouds based on their reflectivity. Since clouds are composed mostly of water vapor they have a higher albedo than the surrounding land surfaces [1]. Some exceptions to this rule include water surfaces and salt plains. The threshold value had to be determined by individual examination of each image. Threshold values of approximately 15 were used for the summer images and values of approximately 9 were used for the winter ones. This method has a tendency to remove the lakes from an image, especially for the winter when lakes are cold. The salt plain is also removed.

Another cloud masking method was the test for negative NDVI. This method did not require a threshold as it simply removed everything from the image that had a negative NDVI. This test had a tendency to remove lakes and the salt plains as well as the thicker clouds.

The last three methods used to cloud mask the data used both channel four and NDVI values. These tests are based on the theory that for vegetated land areas, a larger NDVI corresponds to a cooler temperature due to increased evaporation [2]. This test yeilds the opposite for clouds, which generally have a smaller NDVI for cooler temperatures [2].

By plotting the NDVI versus the channel four values it is possible to see that the relationship between NDVI and channel four varies depending on the image. In the images, a cluster of points with relatively high temperatures and NDVI are associated with land. In the colder images the land points show more variation in temperature than in NDVI. This causes the land cluster to spread out horizontally. In the warmer images the points spread up and back. This is because there is a large variation in NDVI. Furthermore, as the NDVI of the land increases the temperature decreases, for reasons already stated.

In the plot from image 96015a14 (Fig 1), there are two clusters with low NDVI. These clusters represent two distinct clouds in the image. There is also a third clump that is above these two clusters because it has a higher NDVI. This clump represents a third, thinner cloud image. As expected for a cloud, the colder points have a lower NDVI, and the warmer points have higher NDVI values.

For all of the following equations, NDVI is the NDVI value of a pixel, and ch4 is the channel four value of the pixel. The first cloud masking technique uses the following equation, and all values that satisfy the equation are designated as a cloud.

$$[\mathrm{NDVI}] < (\mathrm{threshold})\,[(\mathrm{ch4}) - b]. \qquad (2)$$

where b is the maximum channel four value for the entire image. The threshold is given by the equation

$$(\text{threshold}) = n / (a - b), \qquad (3)$$

where a is the minimum channel four value for the image and n is an NDVI value.

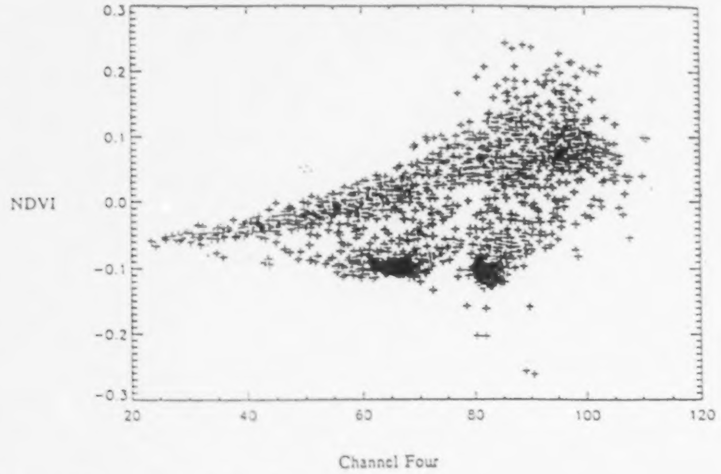

Figure 1: NDVI vs Channel Four for Image 96015a14

This technique was tried on the summer image 96211a14 with n equal to the maximum NDVI value for the image. In this case it may have removed a small amount of land pixels and did not completely remove the warm, high NDVI cloud pixels.

The second NDVI channel four cloud masking technique uses the following equation, where the values that satisfy the equation are clouds.

$$[\text{NDVI}] < (\text{threshold})\,[(\text{ch4}) - b]^2, \qquad (4)$$

where b is the maximum channel four value for the image, and the threshold is given by the equation

$$(\text{threshold}) = n / (a - b)^2, \qquad (5)$$

where a is the maximum channel four value for the entire image, and n is the maximum NDVI value for the entire image.

This test has the tendency not to remove cloud pixels that are warmer with high NDVI values. This can be compensated for by combining the test with others, such as a channel four threshold test. The values for a, b, and n can be altered depending on the image.

In the final channel four NDVI test the equation that must be satisfied to classify pixels as clouds is

$$[NDVI] < \frac{-n \cdot [(ch4) - a] ** 3}{[b - a] ** 3} + n, \qquad (6)$$

where n is the maximum NDVI value for the image, a is the minimum channel four value of the image, and b is another channel four value.

The test was tried on the summer image 96211a14 with b equal to 100. Almost no land pixels were masked and most cloud pixels were. A few warm, high NDVI clouds were still left unmasked. Of the three NDVI channel four masks this appeared to be the most effective.

COMPOSITING

Two methods of NDVI compositing where tried for this study. One involved the direct substitution of values, and the other averaged and then substituted values. Both methods were greatly affect by the quality of the cloud mask applied to the image. The combined channel four, channel one, and negative NDVI mask that was used for these trials was ineffective and there was a lot of noise in the resultant composite.

However, the averaging method was less affected by the presence of clouds. Presumably, it would also lessen the affect of random noise, by lessening the effect of a dramatic change in vegetation cover. Unfortunately, dramatic changes in vegetation cover caused by farming and natural processes, such as fire, might also be lessened by this process.

CONCLUSIONS

The algorithms for the compositing methods were sound. However, the resultant composites were affected by the quality of the cloud masking techniques. This effect was more pronounced in the direct substitution method. Therefore, in order to have a good composite, it is necessary to improve the cloud masking techniques.

It may be possible to significantly improve the quality of the mask produced by the channel four NDVI test with more study. For example, the method used to derive the thresholds could be improved by removing the guess work involved in picking the variables. Furthermore, when a combination of the tests is applied the resulting cloud mask can be improved.

THE UNIVERSITY OF NORTH CAROLINA at ASHEVILLE

JULY, 1997

Foreword for the
Proceedings of the Eleventh National Conference on Undergraduate Research
University of North Carolina at Asheville
April 24-26, 1997

The University of Texas at Austin was pleased to host the 1997 National Conference on Undergraduate Research, affirming its commitment to excellence in undergraduate education and to the research experience in particular. Over 2100 students and faculty attended some 1500+ oral, poster and performing or visual arts presentations scheduled over April 24-26. A special feature of NCUR '97 was a series of more than 30 presentations by faculty members from all disciplines demonstrating the integration of research and teaching with the new technologies. These presentations were capped by a performance on Saturday night of "Ears and Feet," a concert of new interdisciplinary work by student and faculty composers, choreographers, dancers and performers from the UT College of Fine Arts. Electro-acoustic music and modern dance explored interactivity of disciplines and technologies by allowing dancers' movements to control electronic music and robotic lighting by way of a touch-sensitive computer dance floor.

President Robert M. Berdahl opened the conference quoting a Chinese proverb: "I hear and I forget. I see and I remember. I do and I understand." Berdahl praised the research experience as the most practical and potent method to provide students the perspective of inquiry, innovation and exploration as they prepare "for a future that is not so much known to be uncertain, but instead, certainly unknown." That facts and methodologies become obsolete in a world in which developments and advances occur with dizzying rapidity points to the importance of incorporating research activity into the undergraduate experience.

Dr. Berdahl also praised the student-faculty relationships that are fostered by the research process, congratulating the faculty mentor for serving the educational needs of the talented and motivated students by participating in the adventure of exploration and discovery, of cooperation and collaboration which characterize academic life.

Five distinguished plenary speakers addressed conference participants throughout the three days. Dr. Steven Weinberg, Nobel laureate in physics and professor at the University of Texas at Austin, challenged listeners to consider the future of science by posing the questions "The End of Science?". Dr. Robert Williams, Director of the Space Telescope Science Institute, dazzled the audience with the most recent images from the Hubble Space Telescope. From the vastness of space to the minute complexity of genetic research, Dr. Steven McKnight of the UT Southwestern Medical Center at Dallas introduced conference participants to the fascinating work being done in gene regulation and cell differentiation. Friday night's fete "Texas Culture Swing" featured, in addition to an outstanding sampler of culinary and musical styles of the Lone Star state, a mini-plenary address on the multifaceted aspect of Texas border cultures by Dr. Rolando Hinojosa-Smith, distinguished author and professor of Creative Writing. NCUR 97 closed with a resounding standing ovation upon conclusion of "The Challenge of Leadership" by Sarah Weddington, J.D., former Texas legislator and White House assistant, now author, lecturer and adjunct professor.

The University of Texas at Austin is proud of the privilege to share our campus for these few days with the distinguished group of students and faculty whose work is presented here in published form. We congratulate you for your accomplishments and encourage you to continue to participate in the challenge of research.

Susan Wells Howard, Chair, NCUR '97

PREFACE

The 407 papers published in these five volumes are representative of the approximately 1825 papers and posters presented at the celebration of undergraduate research that was NCUR '97'. The faculty, staff and students of the University of Texas at Austin are to be commended for making NCUR '97' such an enriching experience. The student authors deserve recognition for their hard work and for their persistence in seeing their research through to its final publication.

Special thanks are extended to Dr. Susan Howard, Ms. Kelly Johnson and other members of the NCUR '97' staff. Their help during the days of the Conference was invaluable. Many thanks also to the members of the National Board, who reviewed a large number of papers submitted to the *Proceedings* under time constraints. Their continued efforts to standardize has raised the *Proceedings* quality. This project would have not been successful without their assistance.

I would also like to thank the UNCA Editorial Board, who put in many long hours reviewing, checking and organizing papers, and Tracy Walker, and Adam Bradley, who did all the cutting and pasting necessary for these volumes. I owe a special debt of gratitude to Katherine Whatley, Tracy Walker and Mila Cleverdon for their support, encouragement, and mentorship during the entire process of organizing the *Proceedings*.

To all the students who submitted papers to the *Proceedings* go thanks for their participation and congratulations for their achievements. Your enthusiasm and achievement will serve as role models for the next group of student researchers - whom we look forward to meeting at the Twelfth National Conference on Undergraduate Research at Salisbury State University, Salisbury Maryland.

ARTS AND HUMANITIES

Collaborative Art: A Movement in the Twentieth Century 1
Kristen Jo Kerr (Jane-Allen Mckinney)

Nature and the Natural in the Paintings and Prints of Helen Frankenthaler 6
Danielle G. MacCartney (Debora Rindge)

A Comparison of Frank Lloyd Wright and Michael Graves: Furniture Influenced by Architecture 9
Nieya C. Wallace (Jane-Allen McKinney)

Art Education: Art is Underrated as an Instrument for Teaching Essential Learning and Cognition Skills 14
Jennimarie L. Ward (Jane-Allen McKinney)

Toontown: The Disney Tradition Continues 18
Jennifer Lugg (Dianne S. Macleod)

Political Ideologies of Harlaxton Gardens, Harlaxton, Lincolnshire, England 23
Nicole L. Stutzman (Shirley Schwarz)

Reminders of Death and Lessons for Life: Vanitas and Memento Mori Paintings of the Spanish Golden Age (1556-1700) 27
Wendy Singer (Susan V. Webster)

Visualizing the Human Form: Art and Anatomy in Eighteenth-Century England 31
Erin M. Loos (Philip Wilson)

The American Canon: Great Male Playwrights and Their Female Characters 34
Michelle McGovern (Mark Pizzato)

Henry Purcell's Dido and Aeneas: A 1689 Composition Endures Controversy 39
Stacy M. Dieckman (Patricia Kazarow)

Determining the Authorship of the Toccata and Fugue in D Minor, BWV 565 44
Aaron Juhl (Patricia Kazarow)

Plains Attire: The Individual Expression of Culture, the Cultural Expression of Identity 48
Sherri A. Mainord (Anne Guernsey Allen)

Victim vs. Participant: A Comparison of Dmitri Shostakovich's Lady MacBeth of Mtsensk and Katerina Ismailova 53
Heather Miller (Charles McKnight)

New Possibilities in Composition Through Computer Technology 56
Christopher Watts (Daniel Koppelman)

The Conception of "Poet" in the Work of Bei Dao 61
Jennifer L. Berry (Martin Backstrom)

Bei Dao's Poet 66
Jennifer L. Berry (Martin Backstrom)

"There Is No Loneliness Like Theirs": James Wright's "A Blessing" and C.K. Williams' "On Learning of a Friend's Illness" Examined 71

IN SEARCH OF ASPECTS OF THE HUMAN CONDITION IN ANTIQUITY: THE CASE OF A HELLENISTIC POPULATION FROM ABDERA, GREECE

Pia Economou

Department of Anthropology
Adelphi University
Garden City, NY 11530

Faculty Advisor: Dr. Anagnosti Agelarakis

This paper presents important dental information involving a Hellenistic (3rd century B.C. B.C.E.) skeletal population from Abdera, Greece. It is part of a larger interdisciplinary archaeo-anthropological research project carried out by Dr. A. P. Agelarakis of the Department of Anthropology at Adelphi University. This collection consists of the skeletal remains of 51 individuals, 36 of which have preserved dentitions.

The goal of this project was to evaluate dental anthropological data in a laboratory study in order to determine the significance of the occurrence of dental morphology and pathologies, aspects of dietary patterns, and of related manifestations and dental changes which add significant information to the decipherment of aspects of the human condition in the past.

Methods used included background literature research, tabulation of data from the original excavation site, and analysis of information from past research concerning the collection.

Research results include valuable contributions regarding conditions of early life stress which affected the livelihood of these people, organismal growth processes, and the ecology and distribution of dental pathologies. This information provides insight and adds to our understandings about our ancestors pertinent for both present and future scientists and scholars alike.

INTRODUCTION

This study is part of a larger ongoing interdisciplinary project which began in 1984 as a collaborative endeavor between the Greek Archaeological Service and Dr. A. P. Agelarakis of Adelphi University. This paper presents results of physical anthropological and paleo-pathological laboratory analyses in reference to dental surfaces and of their hard supporting tissues recovered from a Hellenistic population dated to the 3rd century B.C./B.C.E. excavated from the site of Abdera, in the coastal plains of Thrace in Greece. Abdera, one of the richest ancient cities of Greece, is located near the mouth of the Nestos river diagonally opposite to the island of Thasos, in the northeastern area of Greece. It was first founded in the 7th century B.C./B.C.E. by the Clazomenaens of Greek Asia Minor seeking refuge from the invading monarchic forces of the Persian Empire (Herodotos: History).

Abdera is also the birth place of great philosophers, Democritus and Protagoras. Democritus is known for developing the atomic theory, which had been introduced by his mentor the philosopher Leucippus, also probably born in Abdera. Protagoras is known as the "first thinker" to call himself a Sophist and the first to teach for fee. He is best remembered by his expression " Man is the measure of all things ".

SAMPLE SIZE, METHODS AND SCOPE OF PAPER

This skeletal collection consisted of fifty-one individuals, thirty-six (68%) of which had preserved dentitions. The skeletal collection included twenty-three males, eighteen (78%) with preserved dentitions, nineteen females, thirteen (68.4%) with preserved dentitions, three individuals which were classified as borderline females, two (66.6%) of which had preserved dentitions, and six individuals which could not be identified as either male or female due to fragmented remains out of which only three (50%) had preserved some fragmented dentitions. The age groups in this collection included individuals within Infancy II, age assessed between 8-12 years, to Senilis, the oldest individual being a male, age assessed at approximately 55-65 years (Agelarakis, database).

The dentitions provide vital information as part of the preserved osseous human record, for deciphering issues of skeletal biology and growth processes, aspects of dietary patterns, range and variation of dental diseases, aspects of dental hygiene and genetic morphological characteristics as variations of dental morphological expressions.

Pertinent studies revolved around tabulations of existing data (Agelarakis, 1994; database and manuscript) through manipulations of the database in order to derive assessments which would carry statistical implications concerning the dental record for understanding interpretations about the human condition during Hellenistic times in Abdera.

RESEARCH RESULTS

Based on the analyses of existing records on the dental remains (Agelarakis, 1994; database and manuscript), it has been determined that out of the eighteen males that had preserved dentitions, eight (44%) were affected by carious cavities. From the females, of the thirteen with preserved dentitions it was determined eight (61.5%) revealed carious cavities, and out of the six individuals in which sex assessment could not be determined, two (33%) showed carious lesions. Carious cavities are the result of infectious conditions affecting and degrading dental hard tissues (Mandel, 1978). The carious process in enamel consists of a diffuse demineralization within the bulk of the lesion that affects crystals in all regions of enamel. However, varying patterns of differential dissolution are often observed thus explaining the different sizes and severity of carious lesions (Ten Cate, 1994). Out of the eighteen individuals with carious cavities, involving both males and females, nine were found to be between 35-55 years of age. The other nine were found primarily to be in the 25-35 age range.

As reflected by the paleo-pathological database, jaws and teeth revealed the presence of periodontal disease. This disease usually begins due to a lack of oral hygiene coupled by the nature of dietary intake and degree of food preparation (Agelarakis, personal communication). It involves the inflammatory and subsequent infectious implications for the gingival components, the clinical and anatomical surfaces of dentitions, as well as the hard tissues of the alveolar bone (Ten Cate, 1994). Evidence of the disease was derived through two assessments: 1) flattened inter-dental septae, compounded with resorbtion of the alveolar bone; and 2) the presence of calculus deposits on the supra-gingival dental surfaces that were formed ante mortem (Agelarakis, 1994; database). It was assessed that sixteen males (88%), sixteen females (88%), two with indetermined sex assessment (33%), and one borderline female (33.3%), possessed characteristics of periodontal disease. Resorption of inter-dental alveolar septae ranged from slight to severe.

Linear enamel hypoplastic (LEH) defects were considered the product of malnutrition and constitutional metabolic disturbances as well as the result of hereditary information (Pindborg, 1982). LEH is further defined as permanent markers of stress that are directly related to metabolic deficiencies. These deficiencies are cases of temporary cessations of growth during periods of stress that occurred during an individual's life, specifically while teeth form inside the alveolar bone of the jaw, whether deciduous or permanent. It was tabulated that six males (26%), had characteristics of LEH ranging from slight, sometimes immeasurable due to calculus build-up, to severe. Only two females (11%), showed slight hypoplasias on their mandibular surfaces. Two (33%) out of the six indetermined individuals showed slight defects, as well as, one from the borderline female category (Agelarakis, 1994; database and manuscript).

Morphology of the dentitions refers to the studies of the surfaces of dental components and of their epigenetic, congenital, and developmental variation, as well as, of their overall shape and size determined by an individual's particular collection of genes or genotype, and on the body's reaction to environmental stimuli (Hillson, 1986). Examples of morphology found in this collection (Agelarakis, 1994; database) included enamel pearls, traits of Carabelli, and varieties of reasons which resulted in mandibular and maxillary excessive dental crowding (Agelarakis, 1994; database). Enamel pearls are small nodules of enamel developing from embryonic enamel tissue usually occurring in a particular proportion of the mandibular second molar (Hillson, 1986). Evidence of enamel pearls were found in only two males (9%), age assessed between the ages of 25-35 years. The trait of Carabelli which is an expression of non-metric variation of epigenetic nature can be found in the form of a cusp, tubercle, groove, or pit at the mesiopalatal cusp of the first maxillary permanent molars (Rogers, 1988), although it might also appear with diminishing frequencies on the second permanent and third permanent maxillary molar (Agelarakis, personal communication). The trait was recorded only among one male, one female and two of indeterminate sex (Agelarakis, 1994; database). All four individuals expressed the trait in a different form, the male in terms of a cusp, the female which had four molars implicated, two in the form of a tubercle, and two in the form of a groove. The two individuals unable to be sex assessed revealed Carabelli forms of the cusp and the tubercle patterns respectively. Out of the thirty-six individuals dental crowding was observed in two males and one female.

DISCUSSION AND CONCLUSION

The data from this research provides scientists and scholars today with opportunities to better comprehend aspects of the life conditions of this population. This information is significant because it gives us a greater understanding as to the habitual conditions of not only the individuals, but of their population and culture. It is extremely important for reconstructions of the paleo-archaeological record to further understand multiple aspects of the environmental conditions, specifically that this population had to endure, to survive. Through the examination of the dental remains a significant amount of information can determine why, and how certain individuals were affected by dental pathologies and non-pathological conditions, and why others were not. As well as how efficiently did those affected with these conditions survive during Hellenistic times.

Based on the results pertaining to carious cavities, it was determined that 35% of the individuals preserving dental remains were affected due to relatively high amounts of starches and sugars in their diets. The high prevalence of periodontal disease and large amounts of calculus build-up allows us to conclude that they experienced insufficiencies in maintaining high standards of oral hygiene, which would have prevented such high prevalence of periodontal disease. We can also assess from the rest of the archaeological record that this population had a very high standard of living in addition to a dietary intake of extremely well prepared food (Agelarakis, personal communication).

Results involving linear enamel hypoplastic activity inferred that there was a low prevalence for this condition, and that in early childhood the majority of the individuals were not affected. This suggests that people living in Abdera had a lower incidence of childhood stresses that affected them in comparison to later archeological populations in Abdera (ibid.).

Even though the results determined through this study only reflect on a relatively small sample of the Hellenistic population found in Abdera, it is nevertheless a random representative sample and it provides pertinent information for present and future scholars in deciphering aspects of the human condition from the past. However, further research endeavors need to take place in order to better elucidate and understand facets of their daily lives. This might even give today's scientists and scholars the opportunity to better see our own lives in a diachronic context of the human condition.

ACKNOWLEDGMENTS

A sincerist thank you to my advisor, Dr. Anagnosti Agelarakis for all his time, patience and continous support with my project. I would also like to thank Adelphi University for providing funding and the opportunity for these research projects to be carried out. A special thank you to Dr. Augusto Hacthoun, Dean of Academic Attainment for his moral support, and Dr. Richard Lund for his technical assistance.

ABSTRACT

The Tehuelches, an aboriginal tribe of the central eastern coast of Argentina, were hunter-gatherers first described by European settlers in the mid 1700's. Recent archaeological findings of Tehuelche burial sites have inspired current anthropological studies, with their abnormal dentition disintegration as a formidable mystery. The three-fold objective of this research project was to (1) utilize five quantitative standards to establish a dental attrition profile, (2) investigate the merits of a micro abrasion theory as the etiological agent of accelerated dental attrition, (3) determine if any significant differences exist between individual teeth relative to the observed standards. The data suggests that complimentary teeth #'s 14 and 19 possessed the greatest levels of dental attrition. The mineral composition of sampled soil was 68% quartz, and only 9% of the teeth possessed clinical calculus; both of these factors suggesting the presence of a cleansing agent. Significant differences between teeth #'s 14,16 and 17,19 were evident in all five quantitative standards. This statistical information will lay the foundation for a possible method of age at death determination, thus complimenting current anthropological methods.

INTRODUCTION

The Tehuelches were an aboriginal tribe of southeastern Argentina, first described by European settlers in the mid 1700's. They were hunter-gatherers, their diet consisting mainly of the nau and hoione (*Lama guanicoe* and *Pterocnemia pennata*, respectively). Two anthropological phenomena of the Tehuelches are of peculiar interest - their unusually tall stature (about 1.9m for males) and the pronounced disintegration of their dentition. Dentition can provide a multitude of anthropological information such as age-at-death, dietary characteristics, oral and systemic health, disease, and genetic affiliation (Kelly and Larsen, 1991). The degree of occlusal surface wear (OSW), for instance, allows one to determine to a certain degree of precision (analogous to that of cranial suture closure) the age-at-death of an individual. Occlusal surface wear, when coupled with other observations such as pulp chamber exposure (PCE), presence of topical or lateral fractures, and peripheral enamel integrity (PEI), can provide a broader dental attrition profile that may be used for dietary reconstructions and for analyzing variances in cariogenic oral flora populations (Tieszen, 1988).

The purpose of this project was to (1) create a Tehuelche dental attrition profile, (2) utilize the abnormal characteristics of this profile to provide a possible cause for accelerated attrition, and (3) establish possible relationships between individual teeth so as to lay the statistical foundation for a highly specific age-at-death determination method. The dental attrition profile consisted of observations in OSW, fractures, PCE, and PED. The etiology of the abnormalities associated with Tehuelche dentition was analyzed with a microabrasion theory as the current predominant theory. Finally, using non-parametric statistical analysis, relationships between teeth were analyzed.

MATERIALS & METHODS

Specimens. Eleven adult Tehuelche specimens (9 males, 2 females) and their 140 individual teeth were observed. Eight of the eleven were from a private collection (C. Brunette, Rawson) and the remaining three were excavated from a burial site in Trelew and Pt. Madryn. Radiocarbon analysis of the later three estimated a mean age of 1149 +/- 200 years.

Standards. Individual teeth were numbered according to the conventional numbering system of 1-32. Only the left arcade (9-16, 17-24) was examined, except for the absence of teeth where the right antimere was examined. Occlusal surface wear (OSW) was determined in accordance with the osteological standards of Smith (1984) (for canines, incisors, and premolars) and Scott (1979) (molars), which provided a progressive score relative to the degree of OSW (1-8 and 0-10, respectively). Using the Scott system, molars were divided into 4 exact quadrants and the mean of the 4 scores determined the overall OSW. Fractures, either topical or lateral, were observed. Pulp chamber exposure was scored on a progressive scale of 1-4, labeled as (1) no PCE, (2) commencing, (3) evident, and (4) well defined. Intermediate values demonstrated transient conditions. Quantitative analysis of PED was determined using an electronic caliper. Enamel condition was categorized as (1) intact, (2) uniform, non-disrupted, (3) disrupted (4) fragmented, (5) absent, and (6) absent, loss below cemantoenamel junction.

Soil Samples. Three random soil samples of burial site stratus were extracted and analyzed, and percent composition of mineral content determined (100X).
Statistics. The Kruskall-Wallis Test for non-parametric variance (where k>2) was used to detect any statistically significant differences (P<0.05) between individual standards.

RESULTS

Standards. The occlusal surface wear data was presented as the mean +/- SEM. Individual dentition standard results are allocated in Table 1. Individual dentition relative to the Scott scale is shown in Figure 1. Fractures on primary and tertiary molars were analyzed (Figure 2). The degree of molar PCE is shown on Figure 3. Molar PEI and their respective categories are shown in Figure 4.
Soil Samples. The three random soil samples contained roughly 68% quartz, 20% feldspar, and the remaining trace minerals were composed mainly of volcanic glass.
Statistical analysis. The Kruskal-Wallis Test determined that there exists significant differences in all applied standards between the primary (T_{14}, T_{19}) and tertiary (T_{16}, T_{17}) molars (Zar, 1984). No statistical differences were found in the other two classes (incisors/canines and premolars, data not shown).

DISCUSSION

Our initial goal was to establish the dental attrition profile and thus provide the basis on which any anthropological inferences to Tehuelche dentition . The numerical analysis of all applied standards demonstrate a dental attrition profile that most notably isolates primary molars as the most deteriorated teeth, whereas tertiary molars seem to be immune to the adverse conditions causing this level of attrition (Figure 4). Occlusal surface wear, the hallmark of dental attrition profiles, was at a score of 34 for T_{14} and 36 for T_{19} indicating these teeth as anatomically useless. The accelerated primary molar PCE associated with massive OSW becomes a liability predisposing an individual to microbial infection, whereas the overall enamel integrity disruption can promote adverse contact wear with teeth that are proximal to it. The microabrasion theory seems to be an appropriate approach in determining the etiology of the accelerated attrition. From the results of the soil samples, one can note that the mineral composition of that stratus of soil was about 68% quartz, which scores a 7 on the Moh's scale. Note that apatite scores a 3. Although enamel is composed mainly of hydroxyapatite and its strength is derived intrastructually rather than as a function of its mineral components, the Moh's scale demonstrates the vast differences in strength between the main mineral component of enamel and that of an abrasive. The culmination of chronic microabrasions coupled with acute destruction caused by the ingestion of animal bones might be a key factor in the Tehuelche dental attrition profile.

The statistical analysis of the profile demonstrates that significant differences exist between the most deteriorated and the most spared dentition, thus establishing the fundamental basis from which to construct an age-at-death determination method specific to Tehuelche dentition. If tertiary molars are said to erupt at age 15 +/- 2 years (Hanihara, 1961), then the differential characteristics between primary and tertiary molars can possibly be used to supplement and compliment current anthropological methods (Walker et al. 1991).

ACKNOWLEDGEMENTS

I wish to thank my mentor, Silvia Dahinten, for her guidance and for allowing me to venture into these uncharted waters in anthropological studies. I wish to give a special thanks to the CONICET researchers in Argentina (Daniel de Lamo, Julieta Otero, Bobby Stewart). I would like to thank Pablo Bouza for his assistance in soil sampling and Susan Pedraza/Mariano Alonso for their statistical assistance. Special thanks are in order for Dr. Flona Redway and Daniel de Lamo for offering me this unique and educational experience, as well as Sr. John Karen Frei for perpetuating the various programs that have become synonymous with the quality education provided at Barry University. Finally, I wish to thank the various grants (NIH-FIC MIRT and NIH-NIGMS MBRS Grants) which funded these projects.

Design of the Acetylcholinesterase
Enzyme Using Brownian Dynamics Simulation
A Novel Therapeutic Approach to Alzheimer's Disease

Brent A. Hanks

Departments of Chemistry, Computer Science, and Biology
Southwestern University at Georgetown
Georgetown, TX 78626

Faculty Advisors

The computational technique of Brownian dynamics simulation was used to investigate the electrostatic and kinetic properties of wild-type and mutant *Torpedo californica* acetylcholinesterase (AChE) under normal and abnormal physiological conditions. This method was implemented by writing a Brownian dynamics program in Borland Pascal 7.0 protected mode. By calculating the electrostatic force field of AChE and simulating the diffusion-controlled reaction of this enzyme with its natural substrate, acetylcholine (ACh), the efficiency constant (k_{cat}/K_m) of the wild-type and mutant forms of AChE could be determined. These calculations have been used to find surface residue mutations that will depress the catalytic activity of this enzyme, thereby offering possible therapeutic alternatives to the treatment of Alzheimer's disease (AD). Simulations have been performed on wild-type, D285A, D285K, E278A, and E278K AChE mutants in low and high dielectric environments. The computed rate constants compare well with experiment and the results show that 1) the abnormally hydrophobic environment of this enzyme in AD is capable of enhancing AChE activity and promoting AD pathogenesis, 2) the E278K mutation is a promising candidate for experimental site-directed mutagenesis studies, and 3) Brownian dynamics simulation coupled with the modern personal computer is capable of offering a strategic methodology to the technique of site-directed mutagenesis and proposing target amino acids for the genetic therapy of human diseases associated with diffusion-controlled enzymes.

BACKGROUND

acetylcholinesterase

The acetylcholinesterase enzyme (AChE) is a 537 amino acid polypeptide that is anchored to the postsynaptic neural membranes in the central nervous system (CNS) and at neuromuscular junctions by a glycosylphosphatidylinositol linkage. The primary physiological role of AChE is to catalyze the hydrolysis of the acetylcholine (ACh) neurotransmitter at cholinergic synapses, resulting in the termination of impulse transmission. This catalytic role is thought to occur at a diffusion-controlled rate which is consistent with rapid neural propagation (Voet and Voet, 1995).

The determination of the three-dimensional structure of the electric ray *Torpedo californica* AChE dimer by Sussman et al. (1991) has shown that the enzyme's monomer is comprised of a 12-stranded mixed β-sheet surrounded by 14 α-helices and that these subunits associate through both a disulfide linkage and hydrophobic interactions. The most prominent structural characteristic of AChE is a deep (~20Å), narrow gorge that leads to the enzyme's catalytic triad of Ser^{200}, His^{440}, and Glu^{327} at its base. The gorge walls are lined with 14 highly conserved aromatic amino acids which have been implicated in guiding the positively charged ACh substrate toward the active site through low-affinity cation-π interactions. The amino acid charge distribution of AChE has been found to create a negative electrostatic field which contributes to its high enzymatic activity. Antosiewicsz et al. (1995) have found that this electrostatic steering effect is capable of guiding the ACh substrate toward the entrance of the AChE active site gorge and increasing the catalytic rate of this enzyme by an order of magnitude.

Alzheimer's disease

Despite decades of intense research efforts, an effective treatment for Azheimer's disease (AD) does not exist and it remains the fourth leading cause of death in the United States today, affecting more than four million Americans and costing society an estimated $100 billion dollars a year (Davis and Powchik, 1995) Many studies have shown that the levels of the ACh neurotransmitter in the cerebral cortex and hippocampus of patients suffering from AD are abnormally low (Rose, 1981) Other pathological markers of AD include senile plaques and neurofibrillary tangles (NFTs) in this same tissue Further work has shown that the distribution of AChE in the cerebral cortex of AD patients is limited to these lesions and that this enzyme's activity is significantly altered under these abnormal physiological conditions (Schatz et al , 1990)

Both senile plaques and NFTs are primarily composed of β-amyloid protein (βAP) fibrils, which have been found to be fragments of an integral membrane glycoprotein termed the amyloid precursor protein (APP) (Hardy and Allsop, 1991) APP processing can occur via two separate pathways a normal secretory route or a pathogenic endosomal/lysosomal route which results in increased βAP deposition (Golde et al , 1992) Nitsch et al (1992) presented an elegant study which showed that ACh activation of muscarinic ACh receptors (mAChR) stimulates the normal secretion of APP through a phospholipase C second messenger system This stimulation, in turn, reduces the degradation of APP through the amyloidogenic endosomal/lysosomal pathway Thus, if the catalytic activity of AChE could be inhibited, elevated levels of the ACh neurotransmitter would be present to bind to mAChRs on neural membranes, thereby resulting in decreased βAP production and reduced brain lesion formation

This work seeks to fulfill four goals 1) to write a Brownian dynamics program which accurately calculates bimolecular enzymatic rate constants, 2) to study the mechanism by which the electrostatic field of AChE contributes to its biological function, 3) to determine if the abnormally hydrophobic physiological environment of AChE in AD is capable of enhancing this enzyme's catalytic activity, and 4) to suggest a mutation which will depress the activity of AChE by altering this enzyme's electrostatic field

METHODS

electrostatics

The enzyme-solvent system was modeled using the 2 8 Å-resolution x-ray crystal structure of the *Torpedo californica* AChE monomer immersed in a homogeneous dielectric continuum (Sussman et al , 1991) Partial atomic charges were assigned according to the OPLS parameter set at neutral pH, generating a net charge of -10e The Coulombic electrostatic force field of the AChE monomer was calculated by centering the enzyme in a 64^3 grid lattice with 4 Å spacing and using the following equation to compute the electrostatic force at each point on the grid

$$F(r) = \frac{e^2}{\varepsilon} \sum_{i=1}^{N} \frac{q_i \mathbf{d}_i}{d_i^3} (1 + \kappa d_i) e^{(-\kappa d_i)} \qquad (1)$$

where e is the charge on an electron, ε is the dielectric constant of the system, N is the number of atoms in the enzyme, q_i is the charge of the ith enzyme atom, d_i is the distance between the ith enzyme atom and the grid point, and κ is the Debye-Huckel ion screening parameter which approximately accounts for the perturbance of solvent ions on charge-charge interactions between the enzyme and its substrate (Allison et al , 1988) This ion screening parameter is defined as

$$\kappa = \sqrt{\frac{2N_A \rho e^2 I}{\varepsilon_o \varepsilon \mathbf{k}_B T}} \qquad (2)$$

where N_A is Avagadro's number, ρ is the density of the solvent, I is the ionic strength of the solvent, ε_o is the permittivity of vacuum, k_B is Boltzmann's constant, and T is the absolute temperature of the system

Brownian dynamics

Diffusion-controlled rate constants were obtained by simulating the reaction of AChE with an ensemble of ACh substrate molecules using the theory of Brownian dynamics This was accomplished by dividing the space around AChE with a spherical surface of radius b and another with a larger radius q, such that all electrostatic interactions beyond b were centrosymmetric (Allison et al , 1985) The diffusional trajectory of an ACh molecule was calculated by randomly placing it on the *b* sphere and using the following Ermak-McCammon algorithm to compute subsequent motion

$$r = r^{o} + \frac{D_{rel}F(r)\Delta t}{\mathbf{k}_{B}T} + S \qquad (3)$$

where r^{o} and r is the location of ACh before and after a trajectory step is taken, D_{rel} is the relative diffusion constant, Δt is the length of a trajectory time step, and S represents a stochastic force due to collisions with solvent molecules having the statistical properties of a Gaussian distribution with zero mean and variance equal to $2D_{rel}\delta_{ij}\Delta t$, where δ_{ij} is the Kronecker delta (Ermak and McCammon, 1978). The electrostatic force on the substrate was calculated by interpolating the pre-calculated force values of the nearest grid points on the lattice by using a three-dimensional Taylor's expansion and solving the derivatives with the method of finite differences. Numerous trajectories were computed to yield a reaction probability of β, which was utilized in the following expression to solve for the diffusion-controlled rate constant

$$k = k_{D}(b)\beta\left[1 - (1 - \beta)\Omega\right]^{-1} \qquad (4)$$

where Ω is probability of a substrate diffusing past the *q* sphere and then returning and $k_{D}(b)$ is the steady-state rate constant at which the ACh molecules penetrate the *b* sphere (Northrup et al., 1984). The following expression has been derived to describe this term

$$k_{D}(b) = 4\pi D_{rel}\left(\int_{b}^{\infty}\frac{e^{U/\mathbf{k}_{B}T}}{r^{2}}\,dr\right)^{-1} \qquad (5)$$

model system

Molecular modeling was used to determine that the hydrodynamic radius of the AChE monomer and ACh were ~30 Å and 4.23 Å, respectively. However, to approximate the active site wall fluctuations of AChE, the substrate was modeled as a positively charged sphere with a radius of 2 Å. Protein atoms were modeled as 1.5 Å spheres. In addition, the *b* and *q* spherical radii were assigned values of 128 Å and 295 Å, respectively. Reaction criteria were satisfied when the substrate sphere diffused within 15 Å of the OG atom of the Ser^{200} catalytic residue. A variable time step algorithm was used with Δt values ranging from 1.25 fs to 800 ps as the substrate approached the outer *q* sphere.

Simulations were performed using 8000 trajectories at a temperature of 300 K, an ionic strength of 5 mM, a solvent density of 996.5 kg/m^{3}, and dielectrics of 78 and 60. All calculations were performed on a Packard Bell personal computer equipped with a 75 MHz Intel Pentium processor. Studies were conducted on the Asp^{285} and Glu^{278} sites, which represent the closest acidic residues to the entrance of the active site (Figure 1).

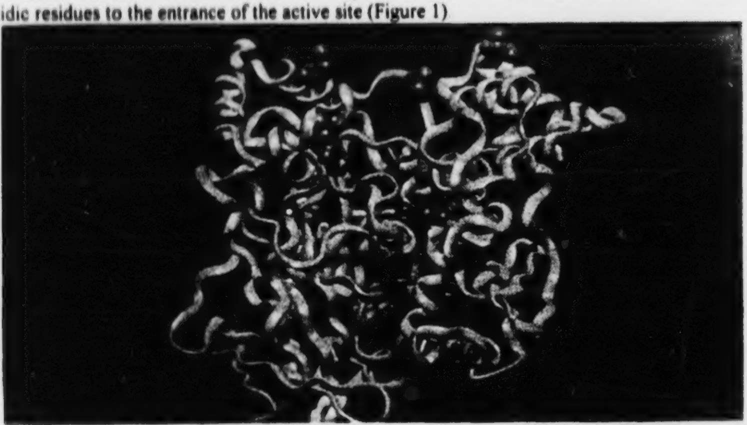

Figure 1. Ribbon Structure of the AChE Monomer. The Asp^{285} and Glu^{278} residues are the center and upper-right modeled amino acids near the active site entrance.

RESULTS

wild-type

The computed rate constant of wild-type AChE at an aqueous dielectric of 78 compares well with the experimental rate constant of 1.6 x 10^9 $M^{-1}s^{-1}$ found for the electric eel *Electrophorus electricus* AChE enzyme under similar conditions (Table 1, Nolte et al., 1980). These simulation results reveal that the abnormally low dielectric medium significantly enhanced the catalytic rate of AChE by a factor of 3.6. Furthermore, the electrostatic force field calculated in this work illustrates the expected gradient emerging from the active site gorge and extending along the enzyme's surface (Figure 2, contours = 5×10^{-12} N). This effectively enlarges the active site target area, resulting in increased enzyme-substrate association.

Table 1 Effect of Dielectric on Activity of wt AChE

Dielectric	Rate Constant $M^{-1}s^{-1}$	Standard Error
78	1.3 x 10^9	± 0.267 x 10^9
60	4.7 x 10^9	± 0.615 x 10^9

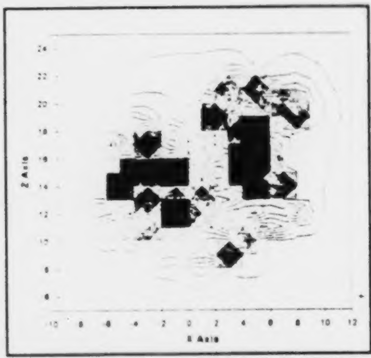

Figure 2 Electrostatic Force Field of wild-type AChE (ε=78). The catalytic Ser^{200} residue is located at (1,15) on the graph

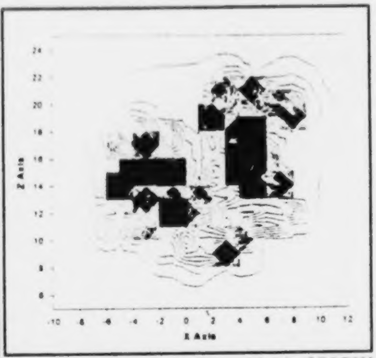

Figure 3 Electrostatic Force Field of E278K AChE (ε=78). The active site gorge lies between z=14 and z=20

glutamic acid-278

Simulations of the E278A mutant produced a K_{mod} value that compares favorably to the K_{mod} found by Shafferman et al. (1994) for human AChE (Table 2). The calculated K_{mod} of 3.36 at a dielectric of 60 compared to the 2.24 value at a dielectric of 78 indicates that the E278K mutation has a larger effect on the kinetics of AChE under hydrophobic conditions. The elevated K_{mod} values and suppressed rate constants for this mutant can be further explained by analyzing its electrostatic force field. Figure 3 shows a new region of positive charge at (-1,17), which is the location of the Glu^{278} residue. This positively charged mutation seems to reduce electrostatic attraction between the enzyme and the substrate as it diffuses near the gorge orifice.

Table 2 Effect of E278 Mutations on Rate Constant of AChE. K_{mod} (modification constant) is defined in this work as the ratio of the wild-type rate constant to the mutant rate constant

Enzyme	Dielectric	Rate Constant ($M^{-1}s^{-1}$)	Standard Error	Calculated K_{mod}	Experimental K_{mod}
E278A	78	6.7 x 10^8	±0.272x10^8	1.94	2.18
E278K	78	5.8 x 10^8	±0.750x10^8	2.24	------
E278K	60	1.4 x 10^9	±0.403x10^9	3.36	------

aspartic acid-285

Mutating AChE at the 285 position failed to significantly affect its activity (Table 3). In addition, the K_{mod} value calculated by neutralizing the Asp^{285} residue is statistically similar to the low experimental K_{mod} found by Shafferman et al. (1994). However, it should be noted that the K_{mod} value for the D285K mutation is larger in the low dielectric medium than in aqueous solution ($\varepsilon=78$), implying that the electrostatic field of AChE plays a larger role in its enzymatic mechanism under hydrophobic conditions

Table 3 Effect of D285 Mutations on Rate Constant of AChE

Enzyme	Dielectric	Rate Constant ($M^{-1}s^{-1}$)	Standard Error	Calculated K_{mod}	Experimental K_{mod}
D285A	78	1.8×10^9	$\pm 0.296 \times 10^9$	0.72	1.12
D285K	78	1.1×10^9	$\pm 0.112 \times 10^9$	1.18	------
D285K	60	2.4×10^9	$\pm 0.511 \times 10^9$	2.04	------

CONCLUSIONS

The reduced rate constants for the E278K mutant in this work are consistent with the work of Shafferman et al (1994) and Antosiewicz et al (1996) who found that the neutralization of this amino acid resulted in the largest decrease in AChE enzymatic activity out of all acidic surface residues The E278K mutation is therefore a promising candidate for experimental site-directed mutagenesis and circular dichroism studies These results also suggest that the abnormal physiological environment of AChE in AD is capable of enhancing this enzyme's surrounding electrostatic field and, in turn, increasing ACh breakdown and subsequent βAP deposition

ACKNOWLEDGMENTS

I am grateful to Drs Walt Potter and Kerry Bruns for many helpful discussions concerning the computer science and biochemical aspects of this project I would also like to thank Dr Vicente Villa for his encouragement

Since the inception of the field of anesthesiology, post-anesthesia nausea and vomiting (PANV) has been an important and common complication resulting from general anesthetics. PANV adversely affects patients' anesthetic experiences in numerous ways and is linked to an increase in health care costs. In the United States alone, it is estimated that between $250,000 and 1.5 million dollars in revenue is lost each year treating patients with PANV. The purpose of this study is to assess the incidence of PANV in patients undergoing general anesthesia in The Methodist Hospital, located in the Texas Medical Center. The study includes data from 150 patients in The Methodist Hospital and is limited to those who underwent surgical procedures that were four hours or shorter in duration. Data collected from patients who are considered to be in the high risk category (those undergoing laparoscopic procedures, women who are menstruating, those who have a history of PANV, etc.) were examined so as to reveal any correlations between their incidence of PANV and the occurrence of PANV in patients who are not in the high risk category. The results of this study are currently being analyzed for statistical significance using logistic regression analysis.

BACKGROUND

Nausea and Vomiting

Nausea is an unpleasant sensation associated with an impending vomiting episode. Vomiting, or emesis, is a forceful removal of gastric contents that is induced by powerful and sustained contractions of the abdominal muscles and is characterized by a descent of the diaphragm and the opening of the gastric cardia. Vomiting is a complex process that can be divided into three distinct phases: pre-ejection, ejection, and post-ejection (Watcha, 1992, 162). The pre-ejection phase involves symptoms that include excessive salivation and swallowing, tachycardia, and nausea. The ejection phase comprises the actual vomiting and retching, which is associated with rhythmic inspiratory movements of the diaphragm and abdominal muscles. During this process the mouth and the glottis remain closed and the contents of the stomach vacillate between the stomach and the esophagus. The post-ejection phase is characterized by a return of the autonomic and visceral phases to a placid state, and usually includes some degree of nausea. The entire emesis process is extremely complex and is controlled by the emetic center of the medulla, which involves the gastrointestinal, respiratory, and abdominal musculature.

The dangers associated with post-anesthesia nausea and vomiting are many. Persistent nausea and vomiting episodes can lead to dehydration and an electrolyte imbalance, which necessitates the use of expensive medications and causes prolonged hospital stays, both of which increase hospital bills and decrease hospital efficiency. Many surgical patients who are asked to answer questions several weeks after surgery, cite PANV as the most uncomfortable and inconvenient aspect of their hospital stay. Patients expect a certain amount of postoperative pain; they expect to dislike the hospital food; and they expect to deal with the lack of privacy that has become synonymous with hospital experiences. They repeatedly and emphatically state, however, that they were not prepared to deal with PANV.

Patient Variables

When conducting an analysis of the causes of PANV it is important to distinguish between and fully consider the relevant patient-related variables and the relevant surgery-related variables. The patient variables that were considered in this study include: age, gender, obesity, patient history, and anxiety. Children between the ages of 8 and 14 will almost invariably experience some sort of nausea and or vomiting after a procedure that involves general anesthesia. Interestingly, however, after adolescence the likelihood of developing PANV increases with age. In addition, patients' gender is also important when considering whether or not to prophylactically treat for PANV. Most studies report that women are much more likely to develop PANV than men are. Hormonal differences are cited as the main reason for this observation (Watcha, 1992, 195). Obesity is another one of the most prevalent patient-related PANV variables. It is linked to postoperative nausea and vomiting due to the absorbent nature of adipose tissue (fat cells), which take in and hold anesthetics, thereby increasing the amount of time it takes for the drugs to be expired from the lungs and body tissues. Finally, patients who are overly nervous and upset prior to induction are more likely to get nauseous and have to vomit after surgery. This is due to the fact that when patients awaken in a strange, new environment, the preoperative feelings of fear and nervousness are recalled and amplified.

Surgical Variables

As previously mentioned, it is also important to consider the surgical factors that play a role in the incidence of PANV. The three that are of the most interest are the type and duration of surgery that a patient is undergoing, and the method of anesthesia that is used during the surgery. Invasive procedures that involve cutting and/or probing into highly vascularized areas lend themselves to postoperative problems like nausea and vomiting. This includes all operations on the abdominal wall and chest cavity, and surgeries involving the stomach, intestines, and bowels are particularly likely to result in an occurrence of PANV. A correlation has also been noted between the duration of a patient's surgery and whether or not they will get sick postoperativly. The longer an operation takes, the longer patients are being subjected to surgical levels of anesthesia, which is directly proportional to their chances of developing PANV. Also, the methods and types of anesthesia employed are related to this condition. Patients whose surgical levels of anesthesia are maintained with inhalation anesthetics (the most commonly used anesthetics) are at a greater risk of developing PANV than are those who are given local anesthetics.

Operations Included in This Study

Patients undergoing laparoscopic procedures, tympanoplasties, vitrectomies, and laminectomies were chosen to participate in this study. Laparoscopic procedures are those in which a surgeon uses a telescopic camera called a laparoscope to look at the uterus, ovaries, appendix, and other abdominal and pelvic organs. Because laparoscopic procedures always center around the abdomen, which is highly a vascularized area, patients who have these procedures almost always have some experience that is related to nausea and or vomiting. Tympanoplasties are performed to repair a tear in the tympanic membrane (the eardrum) or the small bones in the middle ear. Such operations are usually necessary because of a middle-ear infection, an object lodged in the ear, or a loud noise such as an explosion. Since the middle ear is where the senses of balance and spatial relations are controlled, when operations are performed on this area patients often develop PANV as a result of a temporary loss in their sense of balance and their ability to discern spatial relations.

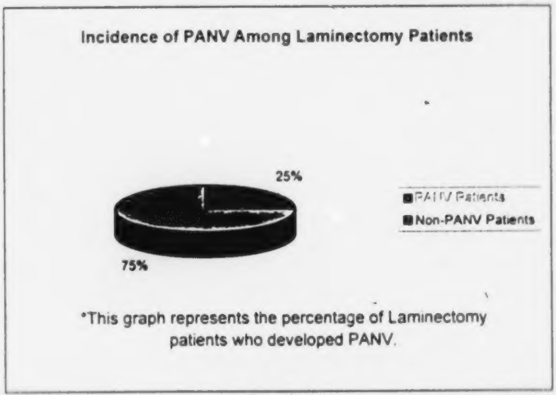
Patients who underwent laminectomies and vitrectomies are grouped into the low-risk category of this study because these operations do not usually result in a high incidence of PANV. Vitrectomies are performed to replace the vitreous membrane of the eye, and laminectomies involve removing a portion of one or several vertebrae, which are located a relatively non-vascular area of the body.

RESULTS

The results of this experiment revealed that there is a reasonably significant incidence of PANV among those patients involved in this study. The percentages of those who developed PANV are listed and summarized in the table below.

Table 1: Incidence of PANV

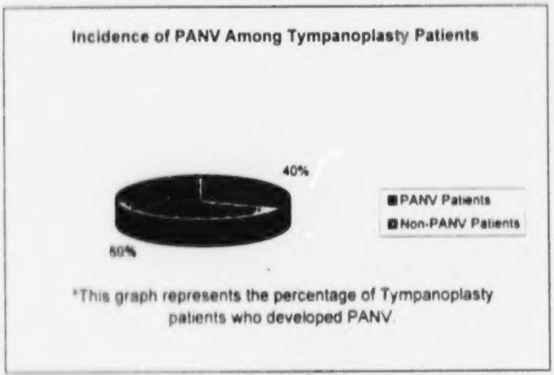
Surgical Procedure	Total Number of Surgeries	Percentage of PANV
Laminectomy	52	25%
Tympanoplasty	10	40%
Vitrectomy	10	60%
Laparoscopy	51	31%



Incidence of PANV Among Laminectomy Patients

*This graph represents the percentage of Laminectomy patients who developed PANV.

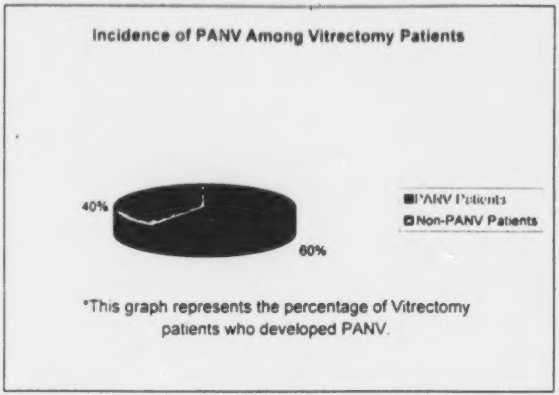
Graph 1



Incidence of PANV Among Tympanoplasty Patients

*This graph represents the percentage of Tympanoplasty patients who developed PANV.

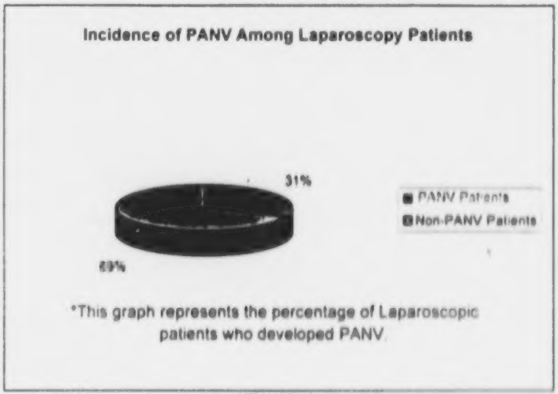
Graph 2



Incidence of PANV Among Vitrectomy Patients

*This graph represents the percentage of Vitrectomy patients who developed PANV.

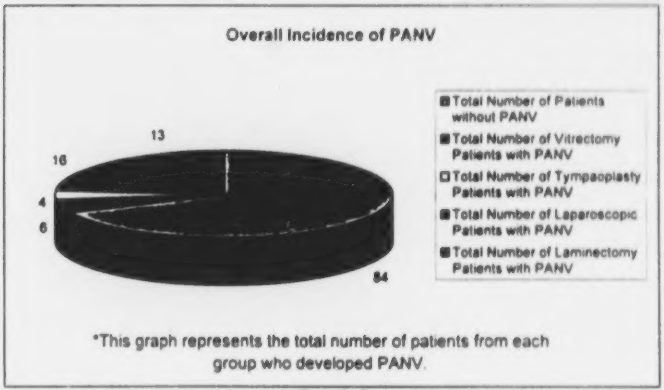
Graph 3



Incidence of PANV Among Laparoscopy Patients

*This graph represents the percentage of Laparoscopic patients who developed PANV.

Graph 4



Overall Incidence of PANV

*This graph represents the total number of patients from each group who developed PANV.

Graph 5

DISCUSSION AND CONCLUSION

A superficial analysis of the data collected indicates that a substantial number of patients undergoing surgical procedures involving the use of general anesthetics have bouts of PANV. It is important, however, that the results listed above in Table 1 are interpreted with the understanding that this study included a relatively small patient population in two areas (specifically, the vitrectomy and tympanoplasty groups). In addition, it must be noted that the results reported above are representative of any and all notations made on patients' charts regarding even the slightest patient complaints of nausea and/or vomiting. In fact, 81% of patients in this study who complained of and were treated for nausea and vomiting, were experiencing mild and transient discomfort that was easily and quickly alleviated with a small dose of an antiemeitc agent such as Phenergan or Reglan.

Although the aforementioned variables must be taken into account when analyzing the results yielded by this project, they do not warrant a dismissal of what this study has revealed. It remains that several of the 123 patients included in this study experienced some sort of postoperative discomfort that is directly related to nausea and vomiting. It was expected that those who underwent laparoscopies (especially those who had a history of nausea and vomiting) would most likely get sick to some degree, but the high incidence of PANV reported in laminectomy and vitrectomy patients was not anticipated.

Although this study reports a high incidence of PANV in patients undergoing general anesthesia, the results do not necessitate a call for wide spread PANV prophylaxis. Such a measure is not necessary and is not cost effective. Instead, we need to more carefully examine the correlation between age, sex, surgery type, etc., and determine a screening protocol that will allow anesthesiologists to prophylactically treat patients who are likely to develop PANV. Preliminary analysis reveals that the most prevalent correlations exist between the duration of an operation, the amount of blood lost during a procedure, and the whether or not a patient has a history of nausea and vomiting. A more extensive examination of the data collected is forthcoming and will reveal the statistical significance of this study's results.

ACKNOWLEDGEMENTS

Dr. Dennis E. Daniels

Over 500,000 Americans experience a cerebrovascular accident (CVA), or stroke, every year. Within the same year, 150,000 die. Today, over 3 million Americans have suffered from a stroke; all of these Americans continue to live some sort of disability. These numbers make stroke the third leading cause of death and the leading cause of disability in the U.S. Everyone is at risk of stroke, especially those older than 65. The Association of Black Cardiologists and LaFayette Singleton conclude that stroke is more prevalent and more deadly in the African-American community than the general population. Approximately 13% of African-Americans are afflicted. They are three to six times more susceptible to CVAs than Whites. African-Americans are also twice as likely to die from a CVA.

The 30% mortality rate due to stroke has experienced a decrease due to improved life expectancy, which is attributed to advancements in medical technology (Modan 1992). About 20% of persons who survive a stroke will die within one month of the infarction. Since the start of the decade, nonfatal strokes seem to be on the rise; the cause of this increase is unknown. Approximately $25 billion is spent annually on medical care for CVAs. On a side note, stroke has been often referred to as "America's Most Neglected Disease," because almost 80% of strokes are preventable.

The major risk factors can be sub-classified into modifiable, non-modifiable, and combination. Most modifiable risk factors are behavioral, such as smoking, alcohol consumption, illegal drug usage, oral contraceptive usage, and physical inactivity. These factors are largely attributed to urbanization within society (Foley 1990). Examples of non-modifiable risk factors include age, gender, geographic location, poverty, and some blood disorders. Combination risk factors, such as hypertension, heart disease, and various blood disorders, have modifiable and non-modifiable risk aspects. Gender, age, geographic location, and race will be the factors of focus.

LITERATURE REVIEW

For our discussion, the following risk factors will be reviewed. They have been identified as significant contributors to the manifestation of a cerebrovascular accident.

Gender is a non-modifiable risk factor for stroke. Stroke tends to affect men at younger ages, women at older ages (Millikan 1987). Men have 30% more strokes than women, up to the age of 65. Men exhibit more risk factors, such as hypertension and poorer health habits, than women. However, women are at an increased risk of stroke after the age of 65 because of the biological effects of aging, as well as the fact that women live longer than men. For women, stroke is the second leading cause of death. Women have a 20% chance of dying from a stroke. In women younger than 45 years of age, strokes are even more common.

Age is a non-modifiable risk factor for stroke. Strokes can affect anyone, regardless of age. Newborns who are afflicted with cerebral palsy often experience stroke. Children who have sickle cell anemia, especially African-American children, also experience strokes (Singleton 1993). In older people, strokes often occur as a result of aging. The biological processes of aging damage the blood vessels, making them more susceptible to obstructions and hemorrhaging. Aging also causes the breakdown of collagen. (Collagen is a protein that forms much of the connective tissue in the body.) Collagen gives blood vessels their strength.

Geographic location is a factor that is thought to increase the risk of stroke. There appears to be an increased incidence of stroke in the Southern and Southeastern United States, a region dubbed the "Stroke Belt." In this area, the death rates due to stroke are 10% higher than the rest of the U.S. This area is the home for over half of the African-American population living in this country, with almost 60% of African-American elderly living in this region (Lassiter 1995). Environmental and social factors are the cause of the increased risk of stroke. African-Americans in the Stroke Belt are two times more at risk for stroke than Whites. This in large part is due to the fact that Afro-Americans in this region are more afflicted with hypertension and obesity than the general population in the rest of the country. In addition, living in an urban setting also increases one's risk of stroke. The social factors that are associated with living in an urbanized region versus a rural region such as crime, violence, and speed of lifestyle (i.e. "hustle and bustle"), all contribute to the increased risk of CVAs.

Race is another non-modifiable risk factor for stroke. African-Americans have the highest stroke rates in the world, in comparison to the majority population. African-Americans are more at risk of cerebrovascular accidents for numerous reasons. Most importantly, African-Americans seem to be afflicted with combination risk factors, such as hypertension and diabetes (Scoch 1996). These two risk factors are more likely to be under-diagnosed and undertreated in African-Americans (Schieszer 1996). Also, it appears that African-Americans are not being taught as well as the general population about modifiable risk factors. Another reason for the increased incidence of CVAs in African-Americans is the prevalence of a high fat diet. "Except for individuals who do not eat pork or any other meat products, African-Americans generally enjoy foods that are high in fat content and highly seasoned, especially with salt" (Lassiter 1995).

BEST COPY AVAILABLE

African-Americans are more likely to experience low socioeconomic status; 30% of African-Americans live below the poverty level. Low socioeconomic status is a significant barrier to proper health care. Poor health is associated with decreased access to health care services, discrimination in the health care system, economics, and poor health care utilization (Lassiter 1995). All of these variables adversely influence one's ability to seek out medical treatment when needed. Further, research on African-American elders suggests that culture and ethnicity have an impact on the health behavior of African-Americans, as well as their utilization of professional health services (Lassiter 1995). Fear of the health care system prevents African-Americans from obtaining information and treatment about serious health issues, including stroke (Schieszer 1996).

Moreover, environmental influences that are associated with low socioeconomic status adversely affect the risk factors for stroke. In relation to socioeconomic status, many African-Americans who experience "conflicts and stressors due to discrimination" are more apt to be afflicted with variables, such as high blood pressure, another risk factor for stroke (Lassiter 1995). Factors such as the individual's "intelligence, education, self-esteem, past experiences, and coping style" all influence the degree to which a social situation can impact the person (Lassiter 1995). If such social issues are not dealt with in a positive, effective manner, then the risk for factors related to stroke, such as hypertension and heart disease, increase.

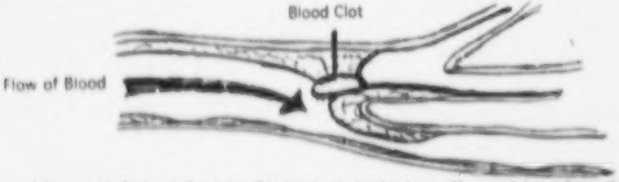
TYPES OF STROKES

The two major types of stroke are ischemic and hemorrhagic. In this discussion, the three sub-classifications of ischemic strokes, thromboses, lacunars, and embolisms will be focused on. Three types of hemorrhagic strokes will also be introduced-- cerebral hemorrhages, subarachnoid hemorrhages, and aneurysms.

Ischemic strokes, or infarctions, result because of a blockage of normal blood flow due to a blood clot or a fatty deposit. They account for 85% of all strokes (Heart and Stroke Facts 1996). An ischemic stroke can result from a thrombosis, an embolism, or a stenosis, defined as the narrowing of an artery leading in or to the brain. Different types of ischemic strokes are characterized by different points of clot origination. The main risk factors for an ischemic stroke include smoking, hypertension, and diabetes (Handbook of Primary Care Medicine 1994).

In a thrombosis, a clot, termed a thrombus, forms in one of the large arteries of the neck, or in the blood vessels within and or on the surface of the brain. The thrombus acts as a stationary plug in stopping the flow of blood to the tissue lying downstream. It is the most common type of stroke, accounting for 65% of all strokes (Heart and Stoke Facts 1996). Thromboses usually form where blood vessels turn, divide, and kink. They occur most frequently in blood vessels that have been damaged by atherosclerosis. A thrombosis usually strikes when a person is inactive or asleep, when blood pressure is low.

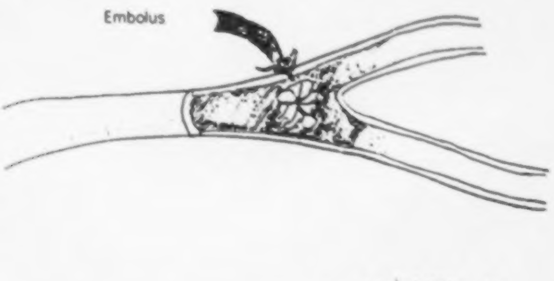
Figure 1: Thrombotic infarction



A lacunar stroke is another type of ischemic stroke that is usually regarded as a form of a thrombosis. In a lacunar stroke, small arteries in the brain are blocked. Lacunar strokes can take anywhere from a few weeks to a few months to become evident (Millikan 1987). Lacunar is derived from the term "lacunae," which means small pit, and refers to the pit that remains after macrophages carry away infarcted tissue from the wall of a blood vessel (Millikan 1987). Lacunaes are often aggravated by hypertension, a significant risk factor for stroke. For this reason, lacunar strokes are very common within the African-American community (Singleton 1993).

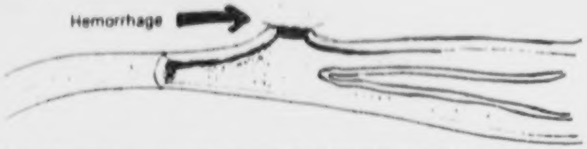
An embolism occurs when a fatty deposit, termed an embolus, forms, then detaches and travels through increasingly narrow blood vessels. An embolus usually forms around diseased heart valves or arteries by the process of atherosclerosis. The embolus becomes wedged in the neck or the brain, since it can neither go backward because of the blood flow nor forward because of its size. Once an embolus is lodged, it deprives tissue downstream of oxygen. Embolisms account for 5 to 14% of strokes, mainly affecting those aged between 56 and 64 years of age. An embolic infarction usually occurs when one is physically active (Heart and Stroke Facts 23).

Figure 2: Depiction of how an embolic infarction arises



Hemorrhagic strokes, characterized by a sudden rupture of a blood vessel, account for 15% of all strokes (Heart and Stroke Facts1996). The blood that escapes the blood vessel disrupts the normal workings of neurons, thus exerting pressure on crucial areas of the brain. This dangerous bleeding to the brain yields higher fatality rates in those afflicted in comparison to ischemic strokes. Hemorrhagic strokes often occur because of long-standing degenerative effects of hypertension, atherosclerosis, or other conditions that might weaken blood vessels. African-Americans are more at risk of hemorrhagic stroke because they are more prone to hypertension.

Figure 3. Depiction of a hemorrhagic stroke



Cerebral hemorrhages, accounting for 10% of all hemorrhages, results when a defective or weakened blood vessel in the brain bleeds or leaks into the surrounding brain tissue. This hemorrhaging, which is usually caused by degenerative changes in blood vessels, occurs deep within the brain's cortex. There is no irreversible injury to the brain tissue, as is the case in ischemic strokes (Foley 1990). The blood that seeps from a ruptured vessel can track between nerve fibers without destroying them (Rose 1981).

An aneurysm is a type of hemorrhagic stroke that usually occurs at the base of the brain. An aneurysm is a weak area or balloon-like weakness which forms a bulge in an artery's wall because of blood pressure. An aneurysm is related to an absence of a muscle layer that comprises part of the blood vessel, which stretches over time and creates a weak area. Most commonly, aneurysms form at branching points of arteries, sites of high turbulence and stress for a blood vessel (Health Report). Usually aneurysms are harmless, but if an aneurysm bursts, the effects are tragic. The result is extreme pressure on nearby surrounding tissues.

In subarachnoid hemorrhages, blood vessels burst within the fluid-filled area of tissue that surrounds the brain. These hemorrhages most commonly result from a head injury or a "massive hypertensive intracerebral hemorrhage that extends from the inside of the brain into the ventricles, and thus into the subarachnoid space" (Millikan 1987). These hemorrhages account for 5% of all hemorrhagic strokes and are most often seen in persons aged between 25 and 50. Most experience a subarachnoid hemorrhage while they are physically active.

DIAGNOSIS AND EFFECTS

Steps to diagnose the affliction begin before the patient is formally admitted to the hospital. A physician gathers data in two manners: examining the patient's medical history for risk factors of stroke and conducting neurological exams. Neurological exams will give information on level of consciousness, orientation, memory, and control of emotion. The main issue is the patient's state of alertness. If the patient is alert for 24 to 48 hours after the onset of the infarction, the mortality rate is less than 25%. The more subdued the patient is, the greater their chances of death. Survival after stroke is also adversely influenced by other variables, such as the age of the victim at the time of stroke or heart failure (Millikan 1987).

In diagnosing a stroke, physicians often use tests that outline affected areas and help define the problem. Four brain-imaging tests are frequently used. A Computerized Axial Tomographic (CAT or CT) Scan is the most well-known imaging tests. In a CT Scan, a computer is used to generate black and white pictures of the brain by way of multiple x-rays beamed through the head, thus enabling doctors to see if there is any bleeding or if the brain has sustained damage from previous "silent strokes" (Donahue 1987). In magnetic resonance imaging, a giant magnet is used to generate detailed images of the brain. A radionuclide angiography, also known as a nuclear brain scan, depicts brain functioning. In this procedure, radioactive compounds are injected into a vein in the arm while a machine depicts a map showing their uptake into different areas of the brain. The experimental Positron Emission Tomography Tests shows how the brain utilizes oxygen, glucose, and other nutrients. It identifies areas that have been weakened or damaged, by identifying which cells are "absorbing the most glucose (active, healthy ones) and which ones are absorbing very little (weakened, damaged ones)" (Donahue 1987).

Other tests measure the electrical activity in order to obtain useful information about how the brain is functioning. In an electroencephalogram (EEG), small electrodes are attached to the scalp to pick-up the electrical impulses that are transmitted and received by brain cells. The impulses are transcribed onto paper by pens that are attached to the machine. In an evoked response test, abnormal areas in the brain can be detected by measuring how the brain handles different sensory stimuli (Foley 1990).

The effects of a CVA are based on numerous factors, including the person, type of stroke, and area of the brain affected. The greater the area of brain damage, the greater the degree of neurological dysfunctioning (Rose 1981). The effects of a stroke can be slight or severe, temporary or permanent. A stroke is more likely to occur in the cerebral cortex, thus affecting the senses, speech, speech comprehension, behavior, and motility (Rose 1981). The effects are also dependent on which brain cells were injured, how widespread the injury is, how well the body repairs the brain's blood supply system, and how quickly other areas of the brain tissue take over the work of the injured cells. (The brain that suffers damage is opposite the side of injury.) Variables that make the patient more susceptible to damaging effects of stroke include intellectual ability, personality, age, sex, general health, and environmental influences (Rose 1981). When the left side of the brain is injured, medically referred to as right hemiplegia, problems with language are exhibited. In right side brain injuries, or left hemiplegia, patients have difficulty with spatial-perceptual tasks.

METHODOLOGY

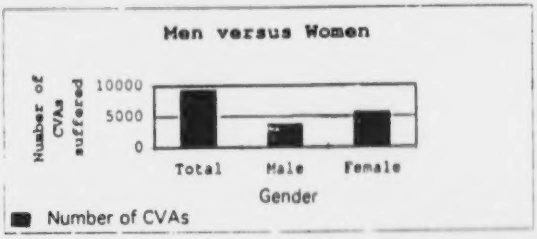
This study of CVA in African-Americans will employ a descriptive study design. Descriptive analysis will be performed in order to describe the existing distribution of variables, without regard to causal or other hypotheses. In doing so, the death certificates of individuals with residence in the state of Texas will be reviewed from 1994. The data tape that will be analyzed was developed by the state of Texas's Vital Statistics Bureau. A computer analysis file of death due to stroke will be generated by the investigator. The analysis will be performed using Number Crunching Statistical Systems (NCSS) software on a person computer (IBM Compatible).

As stated before, for the purposes of this discussion, only these risk factors-- age, race, gender, and geographic location-- will be focused on. The research question is: What is the mortality rate of African-Americans due to stroke in Harris County, Texas? The hypotheses are as follows: Mortality rate among African-Americans is greater than the mortality rate due to stroke among Whites. The mortality rate is greater among men than among women. The mortality rate due to stroke is greater among persons age 55 or older. Aging is associated with CVA. Being male increases the risk of CVA. Certain geographic locations and climates are associated with an increased risk of CVA.

RESULTS and DISCUSSION

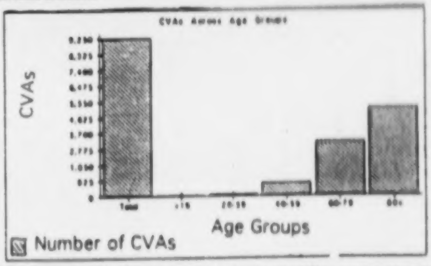
In the following figure, descriptive analysis was performed on the data, which was taken from the State of Texas's 1994 Vital Statistics Data. The number of men and women that experienced CVAs in Texas for that year were charted next to the total number of people living in the state. From the data in this state, it can be concluded that women experience stroke more than men. These results support the literature which states that women experience more stroke than men overall. Stroke tends to affect men at younger ages; stroke affects women at older ages. Furthermore, since women tend to live longer than men, women an increased risk of stroke.

Figure 4:



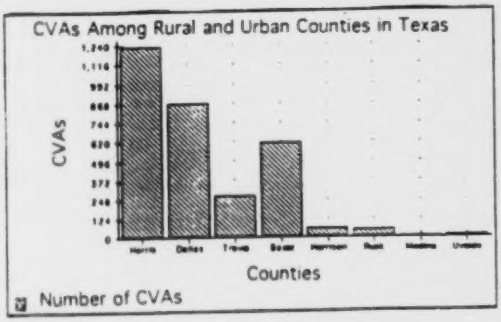
In data that detailed the age at which men and women suffered CVAs, on which descriptive analysis was performed, trends that concur with the literature were found. Older age groups experience more stroke than younger age groups because of the biological processes of aging. Further, African-American children were found to have a greater incidence of stroke than all other children of different races. (Data is not shown.) This finding supports the theory that African-American children experience more strokes because of sickle cell anemia, an inherited blood disorder found often in persons of African descent.

Figure 5:



In the following figure, data from rural and urban counties in the state of Texas were ascertained and analyzed using descriptive analysis. The following counties were examined: Rural counties-- Harrison, Rusk, Medina, Uvalde; Urban counties-- Harris (Houston), Dallas (Dallas), Travis (Austin), Bexar (San Antonio). Regions of Texas, subdivided by Texas's Department of Health, were also analyzed. The data from these areas supports the literature which stated that lower rates of stroke would be found in rural communities, and higher rates of stroke would be found in urban communities. The main factors for the increase in stroke rates in urban areas in comparison to rural areas are: increased population, fast-paced lifestyle, exposure to harmful agents, and diet.

Figure 6.



Race was another risk factor that was analyzed using descriptive analysis. In the following figure, the data from the different races is shown. In this category, the data did not support the literature as well. Yes, African-Americans were at an increased risk of stroke, but the degree to which they were at risk did not concur with that reported in the literature. According to the literature, African-Americans are three to six times more susceptible to CVAs than Whites. In the data that was analyzed, African-Americans may still exhibit the increased risk for stroke, but Whites are experiencing stroke in greater proportions. From the literature, it can be concluded that African-Americans are dying of strokes more frequently than Whites. In addition to being three to six times more likely to experience a CVA, African-Americans suffer more severe strokes than Whites. It appears from the data that although African-Americans are at an increased risk of stroke, Whites are having strokes in greater numbers than African-Americans because they experience less severe strokes and consequently are able to survive them. Other reasons for this discrepancy are still being investigated.

Greenville, SC 29613

Faculty Advisor

Anthony Caterisano

ABSTRACT

The purpose of the study was to compare the effectiveness of two different training positions on leg flexor power. The subjects were twelve untrained male and female college age students. The protocol involved resistance training three times per week over a nine week period using a periodized program. Random selection determined which leg performed prone leg curls, with the other leg trained via standing leg curls. Pre- and Post-tests were conducted on a Kincom isokinetic dynometer at 180°/s. In addition, leg girth and thigh skinfold data were collected.

The legs trained in the prone position showed significantly greater gains in power in comparison to those trained in the standing position. However, no significant gains in muscle size were evident from girth and skinfold data. This suggests that increases in power were due to enhanced neuromuscular fascilitation.

INTRODUCTION

The National Strength and Conditioning Association cites hamstring curls as a important component of resistance training for all sports (Baechle, 1994). Low hamstring strength and ratios of knee flexor to extensor strength were noted as parameters for increased risk for hamstring strains (Yamamoto, 1993). In addition, Yong, et al (1993) determined that hamstring strengthening exercises were successful in diminishing lower back pain.

Therefore, it is important that the best means for improving the performance of the leg flexors is realized. In a previous study, Starky (1994) determined there was no significant difference between 1 and 3 sets for increasing knee flexion isometric torque. In addition, Fry & Powell (1987) found the squat, hip sled, and leg press resulted in equal gains in hamstring strength. However, a parameter that has not been studied is training position. Therefore, the purpose of this study was to compare the effectiveness of the prone and standing training positions on leg flexor power.

METHODS

The subjects were twelve male and female college students (males n=8, females n=4) ages 18-22 yr., none of whom resistance trained their lower body. Before the testing began, the procedures of the study were explained to each subject and a consent form was signed. The subjects were each trained in the proper technique for both supine and standing leg curls. In addition, each subject was required to perform a practice session on the Kincom© isokinetic dynamometer to prevent a learning curve effect between pre- and post-testing.

The treatment involved resistance training three times per week over a nine week period. A periodized resistance program was used which involved three, three week cycles. Cycle one consisted of 4 sets of 10 repetitions; cycle two, 4 sets of 5 repetitions, and cycle three, 4 sets of 3 repetitions. The amount of weight used was moved up 5 lb. each time all sets and repetitions were successfully completed. Random selection determined which leg performed prone leg curls, with the other leg trained via standing leg curls. Subjects were monitored while performing the leg curls to ensure proper position, technique and speed of repetitions. Pre- and Post-tests were conducted on a Kincom© isokinetic dynamometer at 180°/s. In addition, leg girth was measured and thigh skinfold data were collected using a Lange skinfold caliper.

RESULTS

The results of the Kincom© isokinetic dynamometer tests at 180°/s showed significantly greater gains in the prone position (PP). The leg trained in the standing position (SP) yielded concentric torque values of 109.48(± 47.9)ft-lb. for pre-test and 118.18 (±45.7)ft-lb. for post-test yielding a change of 7.4%. The Kincom tests showed significantly ($p < .5$) greater gains for the leg trained in the PP. The pre-test value was 96.24(± 26.75)ft-lb. and the post-test 122.6(±46.9)ft-lb. for an increase of 21.5%. This demonstrated a 14.1% greater increase in power for the leg trained in the PP versus SP.

Circumference and skinfold measurements showed no significant difference between the two positions. For SP circumferences were measured at 52.61(±3.55)cm and 53.03(± 3.48)cm for pre-and post-tests respectively, resulting in a change of 1.0%. In the PP the results were 52.34(± 3.47)cm for the pre-test and 53.09(± 2.74)cm for post-test yielding a difference of 1.4%. The skinfold measurements for the SP were 18.33(± 7.92)mm and 17.87(± 8.30)mm for the pre-and post-tests respectively. This yielded an insignificant change of 2.5%. The PP showed a difference of 7.2% with a pre-test measurement of 19.04(± 8.20) mm and post-test of 17.67(± 8.79)mm.

POSITION	POWER (ft-lb.)	CIRCUMFERENCE(cm)	SKINFOLD (mm)
STANDING			
Pre-test	109.48 ± 47.90	52.61 ± 3.55	18.33 ± 7.92
Post-test	118.18 ± 45.70	53.02 ± 3.48	17.87 ± 8.30
Percent Change (%)	7.4	1.0	2.5
PRONE			
Pre-test	96.24 ± 26.75	52.34 ± 3.47	19.04 ± 8.20
Post-test	122.60± 46.90	53.09 ± 2.74	17.67 ± 8.79
Percent Change (%)	21.5*	1.4	7.2

* $p < .01$

Table -1: Results

DISCUSSION

The results of the leg trained in the PP showed significantly greater gains in power in comparison to those trained in the SP. Because of the limitations of this study, the reason for these findings is unclear. A possible cause of this increase in power in the PP could be because of a greater stabilization in this position. Graves et. al. (1994) showed significantly greater improvements in the isolated lumbar extension strength for the pelvic stabilized group over the unstabilized group although both the pelvic stabilization and unstabilized subjects had significant increases in workload. They cited the exercising of the muscles involved in pelvic rotation as the reason for increases in the weight load for the unstabilized group.

No significant gains in muscle size were evident from girth and skinfold data. Petersen, et.al. (1991) also found no changes in cross-sectional area after 6 weeks of heavy resistance training of the hamstring muscle group. This apparent lack of change in muscle morphology suggests that increases in power were because of enhanced neuromuscular facilitation which is common in resistance programs of this short duration (Fleck & Kraemer, 1988).

Dr. Pamela J. H. Beehler

While measures of long term power output capabilities are important indices of cardiorespiratory health and overall fitness, the availability of immediate energy (anaerobic) resources may be a better indicator of functional capacity in populations with lower limb impairments. The purpose of this study was to expand the Wingate anaerobic power test (WAT) paradigm to include arm cranking in a population of elite wheelchair athletes by determining the optimal absolute load for measuring anaerobic power. Six elite wheelchair basketball athletes were tested over a two day period using a randomized testing schedule. Four resistance loads were tested (3.50, 4.25, 5.00 and 5.75 kg) based on previous pilot work. Power output was analyzed in terms of peak power output (PP) and mean power output (MP). A repeated measures ANOVA was conducted on the dependent variables PP and MP. Significant differences were found between the loads {$p<0.01$, $F(3,15) = 13.090$}, {$p<0.01$, $F(3,15) = 10.736$} for PP and MP respectively. Post-hoc analysis revealed that power output increased as load increased in a curvilinear fashion. The optimal load for this elite wheelchair population was the highest load examined (5.75 kg) for both PP and MP. Additional testing is suggested for identifying the optimal load for non-elite wheelchair populations.

INTRODUCTION

Exercise testing of special populations has gained increasing prominence in recent years. In particular, the lower-limb impaired population has received considerable attention. This interest has been driven by growing participation in wheelchair sports (Wells & Hooker, 1990), the realization of the impact of fitness parameters on functional capacity and cardiorespiratory health and an increasing focus on special populations as a result of the Americans with Disabilities Act of 1992 (Rimmer, Braddock, & Pitetti, 1996). The bulk of previous research has been focused on cardiorespiratory fitness and long term (aerobic) power output resource measurement. While measures of long term power output capabilities are important indices of cardiorespiratory health and overall fitness, the availability of immediate power resources may be a better indicator of functional capacity in populations with lower-limb impairments. Immediate energy expenditure is an essential component of daily activities and sports performance. Most daily wheelchair activity involves a rapid transition from rest to high intensity work and occurs in a time frame which precludes the activation of the aerobic power system as a primary energy source. Immediate power resources are essential for basic mobility, particularly in negotiating environmental barriers, such as ramps and inclines. Performance in short track events and in stop-and-go sports such as basketball depend on the ability to exert immediate explosive force. A comprehensive review of anaerobic power testing of wheelchair athletes has been recently published (Mercer, 1996).

The Wingate Anaerobic Test (WAT) has become widely accepted since its introduction in 1973 (Inbar, Bar-Or, & Skinner, 1996). The WAT consists of 30s of supramaximal cycling or arm cranking against a frictional resistance determined relative to body weight. The arm cranking mode has been found to be reliable in non-disabled populations when population specific resistance loads are used (Bar-Or, 1987). The load factor tends to rely on the participant's activity level, training, and anaerobic characteristics (Dotan & Bar-Or, 1983; Patton, Murphy, & Fredrick, 1985; Gastin, Lawson, Hargreaves, & Fairweather, 1991). The resistance is also highly dependent on the type of ergometer used and the equivalent size of the flywheel.

Results of a pilot study conducted in our laboratory indicated that body weight was not a successful predictor of anaerobic performance in wheelchair athletes (Mercer & Beehler, 1997). This finding opens a question of whether the traditional Wingate paradigm of setting resistance according to body weight is appropriate for this type of population. A two stage absolute load model was proposed where an optimal load might be identified based on maximal velocity performance at a submaximal load. The purpose of this study was to identify an optimal absolute load for a group of elite athletes performing the Wingate test on the Monark 881 arm crank ergometer and explore the feasibility of the proposed multi-stage model.

METHODS

Participants

Six male players from the Dallas Wheelchair Mavericks semi-professional wheelchair basketball team gave informed consent to participate in this study in accordance with the recommendations of the American College of Sports Medicine (1997). Participant characteristics are presented in Table 1. The participants represented a range of disabilities including community ambulators as well as exclusively wheelchair mobile individuals. This study chose to view the athletes from a systems perspective that focused on the results of the available components rather than the specifics of the components themselves. This view allowed the use of a participant group with a mix of disabilities which tends to be most representative of wheelchair basketball. This study measured within-subject characteristics, therefore no control group was necessary.

Instrumentation

A modified Monark 881 Rehab Trainer (Monark, Sweden) was used to perform the Wingate test. The device was modified by attaching a wooden platform for stability and the original kp•m scale was changed during calibration to reflect kilograms of resistance only. The ergometer was positioned so that the upper arms were extended at right angles to the body, with slight flexion at the elbow. An optical sensor integrated with a personal computer was used to determine revolutions covered (Sports Medicine Industries, Chicago, IL.).

Procedures

Participants reported to the laboratory four times over the course of 2 days with a minimum of 1 hour separating each session. Participants completed one 30s WAT at each session according to a previously randomized schedule. Four absolute loads of 3.50, 4.25, 5.00 and 5.75 kg were tested. [Note: These loads are valid only for the Monark 881 and not the Monark cycle ergometers.] Prior to the presentation of the 3.50 kg load, participants also completed a 10s maximal velocity test on the ergometer at a load of 3.00 kg.

Table 1. Participant Characteristics (N = 6)

Subject	Age (yrs)	Weight (kg)	Disability	NWBA Class	Years of Play	Mobile Without Chair
1	31	70.4	Double AK amputation	II	13	With prosthetics
2	38	63.7	Paraplegia T-7	I	15	No
3	38	110.8	Incomplete feet	III	18	Yes
4	24	95.9	Guillian Barre	III	14	Yes
5	24	72.0	Bone disease	III	16	Yes
6	40	55.0	Polio T-7	I	21	With braces
Mean	31.0	82.6		2.4	15.2	
SD	7.26	21.09		0.98	2.93	

Prior to each test, participants warmed up with 2 minutes of cranking at a self-selected "easy" pace and resistance. A moving start was used because of the high cranking rates (130-250 rpm) necessary to achieve peak power and to overcome the inertial resistance of the flywheel. At -10s, a countdown was started (10,9,8,7...) to alert the participant to the beginning of the test. At -2s, the resistance was manually applied. At -1s, the participant was told to begin cranking maximally, so that he would be approaching maximal velocity as the test began. Participants were alerted to the passage of time at intervals of 5s for 30s. Participants completed a two minute cool-down and a 15 minute observation period prior to being dismissed.

Analysis

Pedal counts were converted to power output using Sports Medicine Industries' Power v 3.02 Wingate test acquisition software package. Peak Power (PP) was calculated as the highest power during any 3s interval. Both MP and PP were examined in terms of absolute power (Watts) and relative power (Watts • $kgBW^{-1}$). The rate of fatigue (RF) was calculated as {[PP - Minimum Power/PP] x 100%}. A repeated measures analysis of variance (ANOVA) was performed with the load as the within-subjects factor to determine the significance of load variation on power output. An honestly significant difference (HSD) test post-hoc analysis was performed to determine the significance of differences between loads. Advanced statistics were generated using SPSS v 5 (Statistical Package for the Social Sciences).

RESULTS

Group performance data for the four trials are detailed in Table 2. A repeated measures ANOVA was conducted on the dependent variables PP and MP. The ANOVA results are listed in Table 3. Significant differences were found between the loads {$p<0.01$, $F(3,15) = 13.090$}, {$p<0.01$, $F(3,15) = 10.736$} for PP and MP respectively. Power output increased as load increased in a curvilinear fashion. Post-hoc analysis revealed that the variation in load ceased to generate a significant difference in both mean and peak power at the 5.00 kg load. The optimal load for this elite wheelchair population was considered to be the highest load examined (5.75 kg) for both PP and MP since an attenuated tendency to increase power output was still noticeable past the point where increases ceased to be significant. The criteria for significance determined by the HSD was ≥ 25.29 Watts for PP and ≥ 14.13 Watts for MP ($p<.05$).

Table 2 Group means for absolute and relative power outputs

Load (kg)	3.50	4.25	5.00	5.75
Absolute PP (Watts)	272.29	309.31	338.78	356.68
Relative PP (W/kg)	3.76	4.23	4.59	4.85
Absolute MP (Watts)	211.58	236.79	254.08	259.84
Relative MP (W/kg)	2.87	3.21	3.42	3.51

Table 3 ANOVA Summary Table for Peak Power and Mean Power

PEAK POWER

Source of Variation	df	Mean Square	F	Significance of F
Participants	5	21265.789		
Load	3	9484.654	10.736	000
Participants x Load	15	883.482		
Total	23			

MEAN POWER

Source of Variation	df	Mean Square	F	Significance of F
Participants	5	13704.726		
Load	3	3611.659	13.090	000
Participants x Load	15	275.917		
Total	23			

DISCUSSION

This study was initiated by a search for proven testing procedures in the non-disabled domain which could be applied to individuals with lower limb impairments. The original intent of the research was to conduct validity and reliability testing of the Wingate test with a group of wheelchair athletes to determine its efficacy in evaluating the effects of training programs and predicting performance in wheelchair tasks. A review of the literature revealed that optimal loading factors had not been identified for wheelchair athletes performing the Wingate test. A pilot study was conducted to determine the optimal relative load for a group of competitive wheelchair athletes performing the Wingate test on the Monark 881 arm crank ergometer.

The pilot work indicated that body weight was not a successful predictor of an individual's optimal load, therefore, the relative load paradigm was not appropriate for populations with lower limb impairments. A multi-stage absolute load model was suggested where an optimal load might be identified based on maximal velocity performance at a submaximal load. The purpose of this study was to identify an optimal absolute load for a group of elite athletes and explore the feasibility of the proposed multi-stage model.

The results of this study indicate that the use of lower resistance with the Monark 881 yields significantly lower power outputs. Both mean and peak power demonstrated a curvilinear rise as load was increased. Variation in load ceased to be significant at an absolute load of 5.00 kg. Power output continued an attenuated rise with only one subject experiencing an actual decline in performance. An analysis of individual power output responses to the variation in load indicated that 5.75 kg represented the optimal load for all but one of the participants. The data for the subject with paraplegia conformed to the expected quadratic form with an individual load optima of 4.25 kg. Analysis of the relationship between the maximal velocity response (average rpm for top 3s) to the 3.00 kg load and the individual optimal loads suggests the preliminary testing schematic presented in Table 4. Additional data collection with a more varied subject pool is necessary to further define this schematic.

Table 4. Optimal absolute loads for the Wingate test suggested by highest rpm obtained in a submaximal velocity test

MV$_3$ (rpm)	Optimal Load (kg)
≥ 200	5.75
175-199	5.00
150-174	4.25

CONCLUSIONS

The high degree of variability in individuals with lower-limb impairments challenges the efficacy of the traditional Wingate paradigm of setting resistance according to body weight. Results of a limited sample of elite wheelchair athletes indicate that a loading factor of 5.75 kg is optimal for achieving maximal mean and peak power output in this group when using the Monark 881. Additional testing is required to identify optimal loads for non-elite populations. Future efforts would be best directed towards investigating the potential of a multi-stage absolute load paradigm where an individuals' load for the maximal test would be based on performance at a sub-maximal load.

Author's note

The author wishes to acknowledge the men of the Dallas Wheelchair Mavericks for graciously consenting to take time out from their training camps to participate in this study. A particular debt is owed to Dr. Abu Yilla for his insights into the ecology of the wheelchair user and his guidance in developing this research effort.

INTRODUCTION

Drosophila melanogaster males perform a series of courtship behaviors in response to conspecific females (reviewed by Tompkins, 1984). The most conspicuous of these behaviors is the courtship song, which is produced when the male extends and vibrates one of his wings (Bennet-Clark and Ewing, 1968), and functions to increase female receptivity to copulation (Schilcher, 1976, Kyriacou and Hall, 1982).

Following copulation, *D. melanogaster* females undergo a series of changes, including a reduction in sexual attractiveness and sexual receptivity, along with an increase in oviposition rates (Bastock and Manning, 1955; Mane et al., 1983); Manning, 1967). As a female's sperm supply decreases, her attractiveness and receptivity increase and she will once again stimulate courtship and remate.

The *raised* (*rsd*) stock is a strain of *D. melanogaster* that carries mutations on the third chromosomes that affect the indirect flight muscles, causing the wings to be held upright (Mahaffey et al., 1985). The *rsd* phenotype renders the flies flightless and also prevents makes from producing the courtship song. As expected, the inability to sing causes *rsd* males to be less successful when courting virgin wild-type females. However, virgin females from long-established *rsd* stocks mate readily with *rsd* males (McRobert et al., 1995). Furthermore, mated *rsd* females, (4 days post-copulation) mate more readily with wild-type males than do wild-type females (Presenza and Caesar, 1996). These results suggest that the lack of courtship song in rsd stocks may have functioned as a selective force, favoring mutations that increase the receptivity of both virgin and mates females.

MATERIALS AND METHODS

Stocks

All stocks were maintained in mass culture on Carolina Instant Drosophila Media (Formula 4-24). An Iso-Female line (IF-1) was created by inbreeding the offspring of a single pair of wild-type (Canton-S) flies. All males used in the study were from the IF-1 line, as were control females. The *rsd* flies in this study were obtained from the California Institute of Technology.

Virgin flies were collected under CO_2 anesthesia within 12 hours of eclosion, unless otherwise indicated. Females were stored in groups of 7-10 in vials containing media. Males were stored individually in vials containing media.

Behavioral Assays

All behavioral assays were performed between 9:00 AM and 5:00 PM at room temperature 22° - 25° C. Virgin flies were 3-7 days old when tested, unless otherwise indicated.

Tests with Virgin Females

Onset of Sexual Receptivity

For each trial, females were collected within one hour of eclosion and placed into one of four experimental groups. Females in group one were aged six hours before testing. Group two females were tested at twelve hours post-collection. Group three females were tested at fifteen hours post-collection, and group four females were tested at eighteen hours post-collection. In each test, a single virgin female and one IF-1 male were aspirated, without anesthesia, into a cylindrical vial containing media and observed for sixty minutes. Whether copulation occurred or not was recorded. Each female was tested only once.

Movement Of Virgin Females During Courtship/Copulation Latency

A virgin female and virgin male were aspirated, without anesthesia, into a large cylindrical courtship chamber (vol. ca. 0.4 cm^3) and observed for ten minutes, or until copulation occurred. During this period, the number of times the female crossed a line bisecting the chamber was counted. If copulation occurred, the time was noted and a videotape of the test was reviewed to determine the number of times the female crossed the bisecting line one minute prior to copulation.

Tests With Mated Females

Sexual Attractiveness

Single male-female paired (either IF-1 male x IF-1 female, or IF-1 male x rsd female) were aspirated, without anesthesia, into cylindrical glass vials and observed for 60 minutes. Females that mated within the observation period were removed and stored in groups of 7-10 in fresh media vials, in a 22°C incubator on a 12:12 LD cycle. Four days later, each mated female was aspirated, without anesthesia, into a large courtship chamber (vol. ca. 0.4 cm^3) with a single virgin male. The pair were observed for ten minutes, during which the amount of time that the male spent performing courtship behaviors was determined. From this, the courtship index (CI) was determined.

Dominant-Recessive Effects

Reciprocal heterozygotes were generated by placing 3-5 virgin males and 3-5 virgin females into a vial containing media. Approximately ten days later the parents were removed. Group A heterozygotes consisted of F1 generation of *rsd* males crossed with IF-1 females. Group B heterozygotes consisted of the F1 generation of IF-1 males crossed with *rsd* females. Virgin females from the F1 generation were collected from both groups and aged as in other tests. When mature, single male-female pairs (either IF-1 male x Group A female, or IF-1 male x Group B female) were aspirated, without anesthesia, into cylindrical glass vials containing media, and observed for 60 minutes. Females that mated within the observation period were removed and stored individually in fresh media vials, in a 22°C incubator on a 12:12 LD cycle. Forty-eight hours after the initial mating, each mated female was once again aspirated, without anesthesia, into a media vial containing a virgin IF-1 male and observed for sixty minutes. Females were then removed and stored, individually, for another forty-eight hours. This process was repeated at two, four, six, and eight days post-mating, during which the remating frequency and total number of rematings was determined for each female.

Offspring Production

Mated females were stored individually in vials containing media and stored at 22°C on a 12:12 LD cycle. On day 1 after their initial mating, females were transferred to fresh vials containing media. The total number of larvae in each vial was determined using a sucrose-media submersion technique (Frank et al., in press). In this procedure, a 20% sucrose solution was added to the media and stirred. This allowed the media to sink, while the larvae floated and could easily be counted. Females were transferred every day for ten days, or until they died.

Statistical Analysis

The significance of differences between means was determined by suing a contingency Chi-square test or by calculating t (student's t test, two-tailed). For courtship index tests, the data was arc-sine transformed, before the significance of differences between means was determined by calculating t.

RESULTS

Tests with Virgin Females

Onset of Sexual Receptivity

At six hours post-eclosion, and at twelve hours post-eclosion, no copulation occurred in either line. At fifteen hours post-eclosion, *rsd* females had a significantly higher copulation rate that IF-1 females ($p < 0.02$, Table 1) as did *rsd* females tested at eighteen hours ($p < 0.05$, Table 1).

Table 1 Mating frequencies for young *rsd* and IF-1 females

Six Hours Post-Eclosion

Line	Copulation	Frequency
rsd	0/25	0%
IF-1	0/25	0%

Twelve Hours Post-Eclosion

Line	Copulation	Frequency
rsd	0/25	0%
IF-1	0/25	0%

Fifteen Hours Post-Eclosion

Line	Copulation	Frequency
rsd	5/25	20%
IF-1	0/25	0%
		(p < 0.02)

Eighteen Hours Post Eclosion

Line	Copulation	Frequency
rsd	8/25	32%
IF-1	1/25	4%
		(p < 0.05)

Movement Of Virgin Females During Courtship/Copulation Latency.

During courtship, there was no difference in the total number of lines crossed per minute between virgin *rsd* females and virgin IF-1 females during courtship (p > 0.05, Table 2). There was also no significant difference in the amount of lines crossed one minute prior to copulation between virgin females from the two lines (p > 0.05, Table 2). However, for virgin females that mated, virgin *rsd* females mated significantly faster than virgin IF-1 females (p <0.005, Table 2).

Table 2 Average lines crossed per minute and copulation latency for virgin *rsd* and IF-1 females

Lines Crossed/Minute

Line	N	Mean Lines Crossed/Minute
rsd	25	31.8 ± 10.8
IF-1	25	26.3 ± 8.7 (p > 0.05)

Lines Crossed One Minute Prior to Copulation

Line	N	Mean Lines Crossed
rsd	22	26.1 ± 14.1
IF-1	10	25.5 ± 13.3 (p > 0.05)

Copulation Latency

Line	N	Copulation Latency (seconds)
rsd	22	127.7 ± 81.9
IF-1	10	240.3 ± 122.1 (p < 0.005)

Tests with Mated Females

Sexual Attractiveness

In both lines, all females stimulated courtship four days following their initial mating. However, mated *rsd* females elicited a significantly higher mean courtship index than did IF-1 females (p < 0.01, Table 3).

Table 3 Courtship Index for mated females (four days post mating)

Line	N	Mean Courtship Index (%)
IF-1 females	25	37.3 ± 26.9
rsd females	25	19.7 ± 12.8

Dominant-Recessive Effects

Females from both heterozygote lines (A and B) stimulate vigorous courtship and remated. There was no significant difference in remating frequency between these lines ($p > 0.05$, Table 4). However, as shown in Table 4, the remating frequencies of the heterozygous females were significantly higher than those of IF-1 females ($p < 0.05$), but significantly lower than those of *rsl* females ($p < 0.05$).

Table 4. A comparison of remating frequencies between heterozygous (*rsl*/+), *rsl*, and IF-1 females

Comparison of Reciprocal Crosses

Heterozygote Line	N	Rematings	Frequency
A	30	19/120[1]	15.8%
B	29	16/116[1]	13.9%
			$p > 0.05$

[1] Each female was given an opportunity to mate at 2, 4, 6, and 8 days post-mating. Thus, these figures represents the total number of rematings/opportunity.

Comparison of Heterozygous (*rsl*/+), *rsl* and IF-1 Remating Frequencies

Line	N	Rematings	Frequency*
(*rsl*/+)	59	35/236[1]	14.8%^{ab}
IF-1	25	5/100[1]	5%^{a}
rsl	25	36/100[1]	36%^{b}

[1] These figures represent the total number of rematings/opportunity

* Values with the same superscript are significantly different ($p < 0.05$)

Offspring Production

Mated *rsl* females produced less offspring over a ten day period than did IF-1 females ($p < 0.005$, Table 5).

Table 5. Offspring production for mated *rsl* and IF-1 females

Line	Number of Offspring		
rsl	246.6 ± 77.3	n = 19	
IF-1	356.1 ± 114.9	n = 18	($p < 0.002$)

DISCUSSION

It has been found that *raised* flies carry dominant factory on the X and third chromosomes that increase the sexual receptivity of mature virgin females (McRobert et al., 1995). In this report it was shown that mated *rsl* females are significantly more attractive than mated wild-type females. It has already been shown that the receptivity of mated *rsl* females returns to "virgin-like" levels faster than wild-type females (Presenza and Caesar, 1996), and in this study it was shown that a mated *rsl* females' attractiveness also returns at a faster rate than that seen in mated wild-type females.

Furthermore, mutations in *rsl* stocks affect the onset of receptivity in immature virgin females, causing them to reach sexual maturity significantly faster than wild-type females.

However, *rsl* and control females are not significantly different with regard to their movement during courtship. Females that move slowly elicit more copulation attempts from courting males (McRobert, 1986), and females that do not slow down immediately before copulation mate more quickly than females that do not slow down (Tompkins, et al., 1982). This suggests that *rsl* females do not copulate quickly because they elicit more courtship or move slowly enough to copulate. Rather, *rsl* females mate more quickly because they are more receptive to courting males.

The frequencies at which heterozygous females remated was different from that of *rsd* and wild-type females This could suggest that, with regard to remating, the remating phenotype may not be completely dominant

Mated *rsd* females also produced fewer offspring that wild-type females This could also be a factor that led to the selection for increased receptivity in *rsd* stocks If the number of offspring resulting from a single copulation is low, the fitness of *rsd* parents would be decreased   However, females that regain their receptivity quickly would remate more often and lay more eggs over their lifetime In this way, increased sexual receptivity could lead to increased fitness

THE INFLUENCE OF MENSTRUAL CYCLE PHASES ON THE CHAOTIC BEHAVIOR OF ELECTROCARDIOGRAMS IN COLLEGE-AGE WOMEN

Maria M. Mountis, Meghan Ginty, and Sharee Livingston

Department of Biology
Saint Joseph's University

Faculty Advisor:
James J. Watrous, Ph.D.

The chaotic dynamics of the electrocardiogram (ECG) have been well studied and documented in the literature. These dynamics appear to reflect the normal variability and adaptability necessary for responding to a fluctuating environment. This study focuses on the relationship between the different phases of the menstrual cycle and the chaotic behavior of ECG's. Four females and two males acting as controls had their ECG's recorded three times a week over a ten-week period. ECG's from females exhibited evidence of chaotic dynamics in their Lyapunov Exponent, Capacity and Correlation dimension. The Lyapunov Exponent appears to be the best predictor of cardiovascular changes in women. Significant changes during the different phases of the menstrual cycle occurred, but a phase-specific or gender-specific generalization cannot be made, rather the changes appear to be individual specific. Nevertheless, the analysis of electrocardiograms using the techniques of deterministic chaos can help determine or possibly predict the phases of the menstrual cycle and diagnose pathologies specific to females.

INTRODUCTION

The heart is part of a complex system, involving positive and negative feedback loops that ultimately give rise to very complicated dynamics (Kanters, et al. 1996). Heart rate variability has been studied by many investigators for many different reasons. Some of the mechanisms controlling the variability of heart rate have been well established: e.g. autonomic tone, breathing patterns and diurnal rhythms. The ability to automatically change heart rate appears to be lost or greatly diminished in disease states and the normal aging process (West, 1990). The purpose of this study is to examine the heart rate variability in college-age females, in light of the menstrual cycle, using the techniques of nonlinear dynamics.

The origin of modern nonlinear dynamics, dating back to the late 19th century, is attributed to the mathematician, Henri Poincare. Deterministic chaos or nonlinear dynamics is based on the theory that a Poincare system can exhibit both randomness and periodicity (Bassingthwaighte, 1994). Randomness is characterized by behavior which is disorganized, unpredictable, and non-repetitive. There are some biological processes which exhibit random behavior such as genetic translocation and fertilization. Periodicity is characterized by behavior which is organized, predictable, and repetitive. It is a dynamic system in which equations of motion, variables, and parameters are determined exactly by some rule (Persson & Wagner, 1996). There are some biological processes which exhibit periodic behavior such as sinus rhythm and menstruation. Chaos, while distinct from both of these elements, reflects characteristics of both stochastic and deterministic behavior. Chaotic behavior seems disorganized and random; yet it is deterministic. Chaos can be described as a type of dynamic behavior that shows a sensitive dependence on initial conditions and parameter changes and is quantified by a positive Lyapunov exponent. It is characterized by trajectories diverging exponentially with time, yet it is restrained within a definite area in phase space (Persson & Wagner, 1996). The chaotic system essentially produces random looking results that are not truly random (Peters, 1991). A few biological systems are considered chaotic, such as evolution models, the electroencephalogram, and models of cardiac behavior (Lipsitz & Goldberger, 1992).

Conventional theory stated that the electrocardiogram appeared to be solely periodic in nature; however, the normal human heart appears to exhibit both stochastic and deterministic qualities. Complicated cardiac electrical behavior has already been shown to be explained concisely by nonlinear dynamics mechanisms; in other cases, nonlinear dynamical systems appear to mimic behavior seen in the heart (Kaplan & Goldberger, 1991). In order to establish the heart rate variability, the relationship between heart rate changes and the different phases of the menstrual cycle (menstruation, proliferation, ovulation) are investigated. By incorporating the theory of deterministic chaos or nonlinear dynamics, electrocardiograms may be analyzed, therefore, allowing for the prediction of the onset and duration of the different phases of the menstrual cycle.

There are several techniques, both qualitative and quantitative, which are used for distinguishing dynamical behavior in measured data. The Fast Fourier Transform (FFT) is a method of spectral analysis that results in a graph of the frequency versus the signal amplitude and permits determination of the most predominant frequencies for the data. It essentially consists in converting information in the time domain into information in the frequency domain (Mensier, et al, 1996). Some of the quantitative techniques used to distinguish chaos from periodic and random data include the Lyapunov Exponent, Capacity Dimension, and Correlation Dimension. These parameters ultimately determine variation from individual to individual throughout the various phases of the menstrual cycle. The Lyapunov Exponent is a measure of the rate at which nearby trajectories diverge in phase space and it represents the length of time that a data point will remain in the trajectory (Sprott, 1995). The magnitude of this exponent is related to how chaotic the system is; the larger the exponent, the more chaotic the system. A positive Lyapunov exponent indicates sensitive dependence on initial conditions and is almost without exception diagnostic of chaos (Denton et al, 1990). The capacity and correlation dimensions calculate the minimum number of equations needed to describe the system. Capacity and correlation dimension, which are calculated by successively dividing the phase space with embedding dimension D, should saturate at some value less than five for chaotic data (Sprott, 1995). Correlation dimension describes the complexity of the time series of a chaotic system, and it is considered to be a measure of the number of independent variables needed to describe a particular system (Kanters, et al. 1996). Capacity dimension is more useful for larger data sets, whereas correlation dimension is more useful for smaller data sets.

The theory of chaos in heart rate variability has grown in its usefulness in clinical settings. Research has suggested that heart rate variability consists of interrelated periods with differing non-linear dynamics, leading to the conclusion that heart rate is controlled by a system with numerous attractors (Kanters, et al. 1996). Nonlinear dynamics in cardiac physiology is being studied to determine differences between a healthy heart and certain arrhythmias, abnormal heart rhythms. Using the electrocardiogram records and the results of the qualitative and quantitative parameters, it is then possible for an analysis of chaos in female heart rate variability. This analysis allows for the observation of changes in the heart during the phases of the menstrual cycle, for the possible detection of certain pathologies specific to females, and for the prediction of the different phases, e.g., ovulation.

MATERIALS AND METHODS

Four college-aged female subjects and two college-aged male subjects, acting as controls were used for this study. Each subject was informed of the parameters of the study, before completing a general medical history and signing a consent form. Each female subject had a normal menstrual cycle, averaging twenty-six to thirty-two days in length. All subjects were in good health and physical condition.

Electrocardiograms (ECG's) were recorded either biweekly or triweekly for ten weeks. ECG's were taken for ten minutes at 50 samples per second, generating approximately 4,000 data points, for female subjects in one of the phases of the menstrual cycle (menses, proliferation, ovulation). ECG's were taken for five minutes at 50 samples per second, generating approximately 2,000 data points, for the male subjects, and for the female subjects not in one of the phases of the menstrual cycle. Each female subject's individual cycle length was used in order to calculate the onset of each menstrual phase. The subjects were alert and placed in an upright, quiet position for five minutes prior to data collection in order to minimize external influences. ECG's were recorded through the use of three disposable Vermed EL 503 vinyl electrodes, attached to the inner area of both wrists and to the inner area of the left ankle, which served as the ground electrode.

The BIOPAC System MP 100WS for Windows was used in order to record the data. Shielded leads linked the electrodes to the BIOPAC System. The BIOPAC System also included an EKG 100A amplifier module programmed to receive the wave signals (P, Q, R, S and T waves) with minimal distortion. The wave data was stored in an IBM compatible pentium computer. The Acqknowledge Program (Version 3.0 1994 BIOPAC Systems Inc.) was used to produce a Fast Fourier Transform and to convert the wave data into an ASCII format. The Chaos Data Analyzer Professional Version (1995, J.C. Sprott) was then used to analyze the text file data through both quantitative and qualitative parameters: Lyapunov Exponent, Capacity Dimension, and Correlation Dimension. The calculated values were entered into a spreadsheet and plotted as a function of time using Sigma Plot.

RESULTS

All of the subjects displayed between 3 and 4 peaks in the Fast Fourier Transforms (FFT). The predominant peak (first peak) in females ranged between 1.0 and 1.5 Hz. The remaining peaks were between 1.8 and 5.2 Hz. The predominant peak in the male subjects was 1.2 Hz and the remaining peaks were between 2.5 and 5.2 Hz.

In female Subject N, for example, the predominant peak shifted to the left 30% of the time while in menses, 50 % of the time while in proliferation, and 0% while ovulating. Female Subject K's predominant FFT peak shifted to the left 66% of the time while in menses, 44% of the time while in proliferation, and 100% while ovulating. The predominant peak in male Subject D shifted to the left 50% of the time. Overall, there were distinguishable shifting trends within each of the phases of the menstrual cycle, for all of the individual female subjects, although there was no specific gender-related pattern of shifting.

The phase space plot for all of the subjects showed individual-specific discernible structure, characteristic of a chaotic system. There was noticeable variability in the female subject's plots between consecutive data sets. The greatest variations occurred during the menses phase, where the plots had a less structured appearance (Figure 1). The phase-space plots for the male subjects showed slight variations between consecutive data sets.

The Lyapunov Exponent, Capacity Dimension, and Correlation Dimension values plotted as a function of time showed variation from individual to individual and from one menstrual phase to another. The Lyapunov Exponent for data collected from males was consistently lower than those for all female subjects. In the females tested, the Lyapunov exponent values proved to be inherently greater in variation (Figure 2). The Lyapunov Exponent values were analyzed for increases and decreases between consecutive data sets, however slight or dramatic the change was. In female Subject N, the Lyapunov Exponent values increased 44% of the time while in menses, 43% of the time while in proliferation, and 60% while ovulating. The Lyapunov Exponent values for female Subject K increased 73% of the time while in menses, 50% of the time while in proliferation, and 67% while ovulating. There was an increase between consecutive data sets, for male Subject D, 41% of the time.

The capacity and correlation dimension had values less than 5 in all cases, which is characteristic of a chaotic system. The capacity dimension values were always lower than the correlation dimension values. The capacity and correlation dimension values showed variability but no noticeable phase-specific trends were observed. Therefore, these are less reliable predictors than Lyapunov Exponent in the determination of variability in the heart rate of females during the phases of their menstrual cycle in comparison to males.

DISCUSSION

Chaotic behavior was observed in all six subjects, using Fast Fourier Transforms, graphs of data, and the measured quantitative parameters. Shifting patterns of the predominant peak in the FFTs of the female subjects seemed to be phase related with the most consistency during ovulation. The shifting patterns were less pronounced during menses and proliferation and all shifting trends were individual specific. Movement of the predominant peak in males was relatively equal, in both directions, therefore serving as a control against the females.

A more structured phase-space plot indicates a more chaotic system, whereas a less defined plot represents a more random system. While the phase-space plots for all of the female subjects showed variability from one ECG to the next, the less defined plots during menses seemed to indicate a slight decrease in the chaotic tendencies of the system, during this phase (Figure 1).

Upward and downward shifts in Lyapunov Exponent values are indicative of the increasing and decreasing chaotic nature of a system. Based on this study, females display menstrual cycle related shifts in Lyapunov values (Figure 2). During ovulation, the shifts are more noticeable and are usually more positive thus revealing an increase in chaos. While there was no discernible gender-specific trend, these shifts in chaos seem to be inherent to the individual.

In comparing shifts in the predominant peak of the FFT to the fluctuating Lyapunov Exponent values, there seemed to be a relationship between the up/down and left/right shifts in each individual subject. This was supported by the trends seen in Subjects N and K. In Subject N, there was always an FFT shift to the right and usually an increase in Lyapunov values during ovulation. In Subject K, there was always a shift to the left and an increase Lyapunov values during ovulation. These results show that there may be a relationship between these two parameters but the directionality of the relationship may vary according to the individual.

The Capacity Dimension and Correlation Dimension values showed chaotic behavior since all of the values were less than 5. There were no distinguishable trends observed because of the variability between phases and menstrual cycles in each of the female subjects. Characteristic changes were seen in all subjects but they depend on the individual and therefore cannot be used to make broad generalizations. In this study it was found that Lyapunov Exponent values and FFT shifts were better predictors of the various phase changes of the menstrual cycle, most especially ovulation. However, these findings are based on the individual.

Previous research has shown that the pattern of heart rate variability is reproducible within the same subject, but the differences in patterns between subjects is quite clear. The heart rate variability was found to be unique to each individual subject, but characteristic patterns could not be found to categorize the sample population into subgroups (Kanters, et al, 1996). The findings of the present study support these conclusions, revealing that the parameters of heart rate variability, regarding its chaotic behavior, is indeed individual-specific.

There were a number of factors that could have affected the ECG. These include movement, stress, noise and other external distractions. In the early stages of the study, there was a significant amount of noise appearing on the ECG recordings. This was eliminated, for the most part, by the use of abrasive pads to prepare the area where the electrodes were placed. Thus, promoting better conduction. The data may have also been affected by the small sample size as well as predicting ovulation in the female subjects.

There are a number of practical applications regarding the prediction of menstrual cycle phases based on the chaotic nature of the system. This system can be used to determine pathologies as well as changes in women's health such as fertility problems or menstrual irregularity. Previous studies have shown that a decrease in chaotic behavior in heart rate points to disease or death. These results suggest a relationship between the menstrual cycle and the underlying patterns in the chaotic behavior of heart rate. However, with a larger sample and increased frequency of data collection, more definite conclusions can be drawn about menstrual phase related changes in heart rate.

Pollinated Maize Ovaries Are Resistant to Infection by the Smut Fungus *Ustilago maydis*

Ears of sweet corn (*Zea mays*) were studied to determine if the fungal infection caused by *Ustilago maydis* prevented fertilization and if fertilization prevented infection. Ears were treated in one of four ways: (1) Inoculated only, (2) Inoculated then pollinated four days later, (3) Pollinated only, and (4) Pollinated then inoculated four days later. Ears that were inoculated only and ears that were inoculated then pollinated four days later were both about 75% infected and 7% pollinated. This suggests that infection of an ovary prevents fertilization of that ovary. Ears that were pollinated only were about 77% pollinated and had no infection; ears that were pollinated then inoculated four days later were 73% pollinated and 20% infected. These results indicate that kernels that are pollinated first are protected from subsequent smut infection.

INTRODUCTION

The smut fungus *Ustilago maydis* causes a disease called corn smut that is characterized by the formation of large spore-filled galls in the corn ears. The galls are edible and considered a delicacy, called Cuitlacoche, in several Latin American countries. Studies by Pataky (1991) and Pope and McCarter (1992) have been performed in order to determine an effective inoculation technique to maximize gall yield. Most often, however, studies are aimed at reducing smut infection because it reduces corn crop quality and overall yield, especially in sweet corn (Christensen, 1963). Numerous studies have been performed for almost 300 years in attempts to control this fungal infection of corn crops. According to Christensen (1963), seed treatment experiments have all proven ineffective, and results from other research on crop rotation and cultural practices have not proven effective enough to warrant further study. To date, practical means of reducing smut infection have involved attempts to develop resistant varieties.

Like many pathogenic fungi, *U. maydis* is dimorphic. It grows saprophytically as a yeast when haploid, and only infects plants when two compatible haploid strains mate and form the parasitic filamentous form. The filaments can infect any meristematic parts of the corn plant; most often the ears are infected through the corn stigmas, called silks. Infection hyphae grow between the epidermal cells of the silk, in the direction of the corn ovary (Snetselaar and Mims, 1993). The fungus proliferates within the ovary, and eventually forms galls containing masses of spores within the ovaries of the corn ear. Mature galls break open, allowing spores to be carried by the wind to other susceptible corn plants.

Under normal conditions, the silks are also the route by which pollen tubes grow to the corn ovary and effect fertilization. Wind-borne pollen grains are collected by the silks of a corn ear, pollen tubes form and provide a channel for the pollen nuclei to reach the unfertilized egg in the corn ovary; successful fertilization results in the formation of a kernel. After a pollen tube has grown through the base of the silk into the ovary, a zone of

BEST COPY AVAILABLE

dead cells called an abscission zone forms at the base of the silk (Heslop-Harrison *et al.*, 1985).

Previous workers had noted that when natural pollination of corn plants was prevented, as during the controlled pollination that occurs during hybrid corn production, smut infections seemed to be more serious (Christensen, 1963). The experiments described here used controlled pollination and inoculation techniques to determine whether pollinated ovaries are protected from smut infection.

MATERIALS AND METHODS

The variety Golden Cross Bantam Hybrid sweet corn was used because it is highly susceptible to the *U. maydis* infection. A 36 sq. meter open field plot was roto-tilled one day before sowing, and seven rows of corn were sown and watered during the first week of June, 1996. Two weeks later, the plot was thinned, leaving approximately 20 cm between plants. Only one ear per plant was treated, and 115 ears were harvested.

Plants began to form ears when they were about 1.5 m tall. When silks emerged from the ears, the husks and silks were cut off just above the tip of the ear, and the ear was covered with a numbered ear bag (Lawson). The day following silk cutting, the silks had grown approximately 5-10 cm more. At this time they received one of the four treatments described below.

Pollen from numerous plants was collected each morning using a paper bag, and anthers were separated from the pollen and discarded. The ear bag was removed, silks cut, and the pollen was then evenly sprinkled onto the silks of ears receiving a pollination treatment. Replacement of the bag over the pollinated ear prevented wind pollination or uncontrolled infection. Every cut ear was covered by an ear bag for the duration of the experiment.

Cultures of each of two haploid strains of *U. maydis*, FB1 and FB2 (Banuett and Herskowitz, 1989), were grown at room temperature in dishes of potato-dextrose agar and transferred every four days. The afternoon before an inoculation treatment, a small sample of each culture was transferred to an individual flask containing 10 mL of potato-dextrose broth using the sterile loop technique and then placed on a wrist-action shaker with continuous agitation at room temperature overnight. The following morning the cells were centrifuged at 7,000 rpm for 3 minutes in a benchtop centrifuge and resuspended in sterile water. Optical density was measured with a spectrophotometer at a wavelength of 600 nm. Each culture was prepared so that the optical density was between 0.8 and 1.0.

To produce inoculum, equal volumes of each of the cultures were combined and used within one hour of preparation. Inoculum was injected into the husks surrounding ears with a 22-gauge needle and 10-cc syringe. Depending on the size of the ear, between 1 mL and 5 mL was required per ear.

Four treatments were used: (1) Inoculated only, (2) Inoculated then pollinated four days later, (3) Pollinated only, and (4) Pollinated then inoculated four days later. Ears were treated in the order that they matured. After treatment, ears were kept covered by ear bags so no uncontrolled pollination or infection could occur. Mature ears were harvested, husked, and categorized within treatments (1-4) according to the percent of the ear pollinated, infected, and neither pollinated nor infected. Any kernel not showing any sign of infection was counted as a kernel; any kernel with fungus growing in or on it was considered infected.

RESULTS

115 ears were harvested and analyzed in early August, 1996. For all treatments, the majority of kernels was located at the base of the ears and that the majority of infection was located the top of the ear (Fig. 1).

Mean percent infection and pollination for each treatment are shown in Figure 2. For Treatment 1 (Inoculated only), ears were about 75.0% infected and 7.3% pollinated. Ears from Treatment 2 (Inoculated then pollinated four days later) had a mean infection of 73.9% and mean pollination of 8.2%. Thus, mean infection and pollination frequencies from ears from these two treatments were very similar.

Mean percent infection and pollination for treatments 3 and 4 were very different (Fig. 2). For Treatment 3 (Pollinated only) ears were on average 77.1% pollinated and there was no infection in any ears. Ears from Treatment 4 (Pollinated then inoculated four days later) were on average 74.6% pollinated and 20.4% infected.

DISCUSSION

Previous workers have sometimes had difficulty in obtaining controlled infection of corn ears with *U. maydis* (Christensen, 1963). The injection method described here allowed reliable infection of ears. Likewise, the pollination technique resulted in high rates of kernel formation in control ears.

Results of the experiments where ears were both pollinated and inoculated indicate that when individual ovaries are pollinated they become less susceptible to smut infection. When individual ovaries are first infected with *U. maydis* they do not form the normal kernels that result from pollination and fertilization. Thus, it seems that pollination and smut infection are mutually exclusive processes for each ovary. This conclusion is supported by what is known about the pollination and infection processes. Pollen tubes grow rapidly through the silks to the ovaries, and when several pollen tubes have passed through the base of a silk, a zone of dead cells forms at the base of the silk. This prevents additional pollen tubes from entering the ovary (Heslop-Harrison *et al.*, 1985). The dead cells may also prevent the fungus from growing into the ovary. *Ustilago maydis* is a biotrophic fungi; it grows only in living cells of its host (Snetselaar and Mims, 1993).

Pollination did not protect entire ears from later infection; there was a low level of smut gall formation in ears that were pollinated and then infected. It is important to note, however, that these galls were primarily found in the upper part of the ear (Fig. 2C). This same part of the ear was poorly pollinated in control ears (Fig. 2A). Again, this indicates that unpollinated kernels are more susceptible to smut infection.

Much corn grown commercially today is hybrid corn, and production of hybrid seed often involves controlled crosses between parent corn varieties. Self-pollination must be prevented for hybrid corn production, and this is often effected by mechanical removal of the pollen-producing tassles. Previous authors (e. g. Christensen, 1963) have noted that detasseled corn plants seemed more susceptible to smut infection and hypothesized that the detasseling process created wounds in the plant that allowed the fungus to enter. This study suggests, however, that the increased susceptibility to smut infection in these plants occurs because there is no pollen to fertilize the corn ovaries.

This finding opens up some new possibilities in terms of selecting for resistance to smut infection. Typically, resistant varieties are selected simply on the basis of field trials, and the mechanism by which some corn varieties are resistant to *U. maydis* is unknown. Based on the results described here, it might be profitable to concentrate on characters of the male gametophyte (i.e. the pollen grains) in looking for resistance to corn smut. For example, corn with fast-growing pollen tubes might be more resistant to the fungal infection, and it would be quite easy to screen for this character.

A number of smut-resistant corn hybrids are available, so seeking new sources of resistance to the fungus is not a high priority. However, there are other more serious diseases caused by smut fungi that infect the ovaries of the host and thus prevent formation of fruits and seeds. For example, the crop pearl millet is an important food source in some dry regions of the world, especially certain parts of Africa. Pearl millet yields are seriously damaged by an ovary-infecting smut that seems to infect in the same way as *U. maydis*. Perhaps screening for fast-growing pollen in this species will be productive.

ACKNOWLEDGMENTS

The authors thank the Howard Hughes Medical Research Institute (Grant #71194-535101) for funding this research. We are also grateful to Dr. Maureen Knabb at West Chester University for announcing this opportunity for the summer of 1996.

Faculty Advisor:
Dr. Lawrence Hobbie

ABSTRACT

The objective of this research is to understand the effects of the plant hormone auxin in Arabidopsis thaliana and to identify and study the genes that regulate the action of this hormone. Characterizing the mutant genes genetically is important in understanding the normal function of the genes involved in the action of auxin. Standard procedures were used to cross the axr5-1 mutant plant with three visible markers: hy4, abi1, and pr1, which are located on chromosome 4. These crosses will allow us to determine the different types of progeny in the F2 population which will enable us to map the AXR5 gene relative to these visible markers on chromosome 4.

INTRODUCTION:

Auxin is a small molecule that is important in plant growth and development. The naturally occurring form of auxin is indole-3-acetic acid, or IAA. However, a variety of synthetic compounds such as naphthalene acetic acid and 2,4-D (dichlorophenoxyacetic acid) have been identified that behave like auxin. Auxin causes elongation when present in the right concentration and in the right tissue. Auxin is important for phototropism. In response to light, the distribution of auxin in a stem tip changes in such a way that there is more auxin on the side away from the light. The cells of the side which contains more auxin elongates more than the cells on the side near the light. In a similar fashion, auxin is also involved in gravitropism, plants response to gravity. In addition to cell elongation, auxin is also involved in cell division and differentiation.

A genetic approach is being used to understand auxin's effects in these cellular processes. For example, to understand the genes important for the role of auxin in root elongation, we need to isolate mutant seedlings altered in root elongation in response to auxin. We are characterizing mutant plants genetically and physiologically to understand the normal function of the gene. The root growth of the wild type seedlings is inhibited by high concentration of auxin. We are studying a mutant of the weed Arabidopsis thaliana, called *axr5*, that elongates roots on high concentration of auxin. Arabidopsis is used because it is small and grows fast, so laboratory studies can be done easily. This organism also has less junk DNA which makes it easier to clone. Arabidopsis is relative of broccoli and mustard. It has only five chromosomes. The *axr5* mutant was isolated in the lab of Dr. Mark Estelle at Indiana University by Jim Britton and Anna Ruesink. The *axr5* mutant is a single allele that is dominant and auxin-resistant.

Dr. Hobbie has roughly mapped the *axr5* mutant, positioning the *AXR5* gene on chromosome 4, but it needs to be mapped more closely (Dr. Hobbie, unpublished results). Our research involves positioning the *axr5* mutant relative to three visible markers: *abi1*, *prl*, and *hy4*, which are located on chromosome 4. *abi1* is a dominant mutant that is resistant to abscisic acid, a plant hormone that imposes seed dormancy and inhibits seed germination. *hy4* mutant plants have longer hypocotyls compared to the wild type. Heterozygous *prl* mutant plants are resistant to kanamycin and homozygous *prl* mutants are dead. The results and analysis of F_2 population produced by crossing *axr5* to each of these mutant plants individually will be described.

MATERIALS AND METHODS

axr5 x hy4 cross Wild type, *axr5*, *hy4*, and the F_2 seeds of the *axr5* x *hy4* cross were sterilized and spread on 2D Plates. These plates contain $2x10^{-7}$ M 2,4-dichlorophenoxyacetic acid, a synthetic auxin, along with 0.7% agar, 1% sucrose and a mixture of salts and minerals (Wilson et al., 1990). These plates were placed at 4 °C for two days, and then put into a Percival Scientific Growth Chamber set at 16 hour light and 8 hour dark cycle at 22 °C for one week. This growth chamber has a light intensity of 70-95 microEinstien M^{-2}/S^{2}.
axr5 x abi1 cross Wild type, *axr5*, *abi1*, and the F_2 seeds of the *axr5* and abi1 cross were sterilized. The sterilized seeds were then spread onto plates that contained 10 µM abscisic acid. The plates were given cold treat (4 °C) for two days and then placed in the growth chamber for one week. After a week, the nongerminated seeds were transferred onto 2D plates or 2,4-D plates. The plates were placed in the growth chamber for one week. The purpose of this method was to distinguish between the four phenotypes of the F_2 seedlings.
axr5 x prl cross Wild type, *axr5*, *prl*, and F_2 seeds of *axr5* x *prl* were sterilized and spread onto 2D plates. The plates were then placed at 4 °C for four days. The plates were put in the growth chamber for one week. At the end of the week, the $auxin^R$ and $auxin^S$ seedlings were separated and transferred onto plates containing 5o µg per milliliter Kanamycin. These plates were then put in the growth chamber for a week. After a week, the Kan^S and Kan^R seedlings were separated and the F_2 population was scored.

RESULTS

To measure the genetic distance between the *AXR5* gene and other chromosome 4 markers, F_2 populations resulting from crosses between *axr5* mutant and other genes on chromosome 4 were analyzed. Results are presented in tables 1, 2, and 3.

Calculation of Map Distance For Table #1 Using the Product-Ratio Methods (F_1 in Coupling Phase)

According to the Product-Ratio Method, a value of z is determined by the following formula : (LR, LH) x (SR, SH/(LR, SH) x (SR, LH). This z value corresponds to a recombination frequency of x (Stansfiel, 3th Ed.).

Coupling Data: (LR, LH) x (SR, SH)/(LR, SH) x (SR, LH)
(246) x (83)/ (2788) x (1246) = 0.00587

Using the product ratio table, we can conclude that 0.00587 lies between the values of 0.005318 and 0.007366. This corresponds to recombination frequency of 0.06 and 0.07 respectively. Thus, the recombination is approximately 6% which corresponds to a map distance of 6 cM.

the Square-Root Method (F_1 in Repulsion Phase)
F_2:

Frequency of double recessive = 55/731 = 0.0752
Percentage of crossover gametes = 2 √ frequency of double recessive =
2√ 0.0752 = 0.548 =54.9 %.

DISCUSSION

The presence of recombinant type gametes indicates the event of crossover. The F_2 populations are produced by self-fertilizing the F_1 generation. Such an F_2 generation does not show the typical independent assortment ratio of 9:3:3:1. This lack of independent assortment ratio is used as an evidence for linkage. In this part of our paper, two methods used for estimating the degree of linkage from F_2 data will be presented.

Product-Ratio Method. This method utilizes the F_2 phenotypes to estimate the frequency of recombination from double-heterozygous parents. In order to use this method, it is important to know whether the F_1 was in coupling phase or in repulsion phase. The F_1 is in coupling phase if the dominant alleles of two genes are on the same chromosome, which is true for *axr5* x *hy4* cross. F_1 is in repulsion phase if the dominant alleles are on two different chromosomes. Since the *axr5* and *hy4* mutations are on the same chromosomes and there are four possible phenotypes from the F_2 generation, the product-ratio method was used to estimate the distance between the *AXR5* and *HY4* genes. The calculation indicated that the *AXR5* is 6 map units or 6cM (centiMorgan) away from *HY4*.

The frequency of recombination increases as the distance between linked genes increases, but it will never exceed a maximum of 50%. Since the frequency of recombination of the *axr5* and *abi1* cross is 78 %, we can conclude that the two genes are spaced far apart on chromosome 4 and do not appear to be genetically linked.

Our calculation for the *axr5* and *prl* cross also indicated that the frequency of recombination is more than 50% which enables us to conclude that the *AXR5* and *PRL* genes are not genetically linked. There appear to be some contradiction in the results as *AXR5* is closely linked to the *Hy4* gene (6cM), yet appears unlinked to *PRL* gene which is 22.7 map units (according to one measure of map distance, that using recombination inbred lines) away from *HY4*. The F_3 progeny of the *axr5* x *hy4* cross is currently being retested to verify our F_2 results. The analysis of the *axr5* x *prl* cross will also be repeated to verify the results.

Exact positioning of the *AXR5* gene on the genetic and molecular maps of chromosome 4 will be the first step in cloning the *AXR5* gene by a position cloning approach.

After the submission of this paper, it was noted that the *prl* mutation has reduced transmission of gametes and behaves differently than the wild type. Due to this reduced transmission of gametes, the Square-Root Method can not be used. After accounting for this, it was calculated that the *AXR5* gene is 34 map units away from *PRL*. Furthermore, after retesting the F_3 progeny of *axr5* x *hy4* cross, the results indicated that the *AXR5* gene is 3 map units away from *HY4*.

Since *HY4* is 58 map units away from *ABI1* and *AXR5* is 3 map units away from *HY4*, it is logical to conclude that the *AXR5* gene will show no linkage to *ABI1*, as supported by the findings presented in this paper. If *PRL* is 22 map units away from *HY4* and *AXR5* is 3 map units away from *HY4*, the *PRL* gene will be less than 34 map units away from *AXR5*. However, it is not surprising that the map distances do not add up perfectly because it is often difficult to compare map

distances derived from different crosses.

The Competitive Relationship Between the Perennial *Cardaria draba* and the Annual *Lepidium virginicum*

Life history predicts that perennials, having a higher investment in vegetative rather than reproductive structures, should be superior to annuals in their ability to compete for resources. To investigate this hypothesis and to determine if this competitive relationship was affected by a delay in seedling emergence, the perennial *Cardaria draba* and the annual *Lepidium virginicum* were planted alone and together in 4 inch pots. In each pot, a focal plant was surrounded by five neighbors of either the same or the other species, and seeds of the focal plant were planted at the same time as the neighbors or five days later. Relative competitive ability was assessed by measuring root and shoot dry masses of the focal plants. At harvest, the perennial had higher root and shoot biomass under all treatments. For planting times, the annual had its higher shoot mass in intraspecific treatments and the perennial had its higher shoot mass in interspecific treatments. In the simultaneous plantings, the perennial had a higher root: shoot mass ratio than the annual but the annual had a higher root: shoot ratio in the delayed planting. This, combined with the large decrease in shoot mass of the annual in the delayed planting, indicates the more dramatic effect of competition on the annual. These results demonstrate that the perennial's higher allocation to vegetative structures (roots and shoots) may make it a superior competitor over the annual.

BACKGROUND

The life history of a species describes the timing and pattern of vegetative and reproductive stages. In plants, differing life histories are sometimes classified into two categories: early-successional species, including most annual, and late-successional species, including most perennials (Huston and Smith 1987). Annuals complete their entire life cycle within a single year and tend to allocate a larger portion of their energetic and mineral resources to reproductive rather than to vegetative organs, such as roots, primarily because they have only one chance to reproduce. Several studies have demonstrated that annuals have greater reproductive effort, greater seed and fruit production per unit leaf area (Abrahamson 1979; Primack 1979) and allocate a much smaller portion of their resources to roots (Pitelka 1977) than do perennial species. In contrast, the perennial life cycle extends over many years and typically includes many fruiting periods, translating into a larger prereproductive investment in vegetative structures (root, shoots, leaves). Vegetative organisms have limited energy and resources that must be allocated differentially to growth, reproduction, and defense. Because of energetic and physiological constraints, trade-offs result when a plant allocates resources to one function rather than to another.

An interesting question in plant ecology concerns the relationship between life history (e.g. annuals vs. perennials) and competitive ability. In general, annuals, which lack a persistent root system, make better competitors in disturbed environments where adult mortality is great, while perennials fare best in a stable environment where selection favors the longer-living plant (Huston and Smith 1987). In addition to such environment-specific differences in competitive abilities, annuals and perennials compete differently due to variable allocation patterns and life histories.

Perennials, which have slower growth rates than annuals but a greater investment in roots and vegetative structures, tend to be superior long-term competitors. Annuals, which are characterized by high seed output and dispersibility, high stress tolerance, small seed size and rapid growth, are better competitors in the low population densities of early succession, as well as in disturbed environments where density-dependent mortality (e.g. environmental stochasticity) is high. Conversely, perennials are superior competitors in stable environments where the adult plant is favored and density-dependent mortality (e.g. from competition) is high.

A relevant study by Pitelka (1977) delineated the differential energy allocation patterns between the annual *Lupinus nanus* and the perennial herb *Lupinus variicolor*. The annual devoted 61% of its energy to reproductive tissues, 29% to seeds alone, and only 3-4% to roots. In contrast, the perennial devoted only 18% to reproduction and at least 40% of its energy to a large taproot system. Consequentially, *L. variicolor* was found to thrive in climatically harsh but stable environments where high survivability is favored (Pitelka 1977).

A second variable in my experiment was the timing of seedling emergence. This effect was evaluated in my experiment to determine if delayed seedling emergence would affect competitive ability and if this effect differed between annuals and perennials. Based on the competitive disadvantages tied to late germination, it seems likely that delayed plants in my experiment would have a lower final biomasss. Indeed, it is widely known that germination rate and seedling emergence can have a profound effect on plant populations (Ross and Harper 1972; Miller 1987). Experiments have indicated that small alterations in emergence time can contribute greatly to the final biomass of the plant. For example, when grown with competition, the mean final biomass of *Dactylis glomerata* increased by an average of 222% from a simultaneous planting when the plant received one day's headstart (Ross and Harper 1972). Other experiments have shown similar results (Black and Wilkinson 1963; Miller 1987).

Thus, the competitive abilities of the perennial, *Cardaria draba*, and the annual *Lepidium virginicum* were investigated, by comparing biomass allocation patterns to roots and shoots, and in the focal plants whose seedlings emerged concurrent with, and subsequent to, seedlings of competing neighbors.

METHODS AND MATERIALS

This experiment examined two members of the Brassicaceae (mustard family) because of their morphological similarity and tendency to co-occur in the U.S. (Agricultural Research Service 1971). This diverse family contains more than 3500 species in 300 genera including weedy species as well as agricultural relatives such as cabbage, cauliflower and broccoli (Agricultural Research Service 1971). *Lepidium virginicum* L. (Virginia pepperweed) is an annual or a winter annual herb, reproducing by seeds. It grows 20-90 cm tall and produces coarsely toothed leaves on a linear stem and inflorescences in elongate racemes with small white or greenish flowers. Native to most the U.S., it grows from May to December and can often be found growing as a weed in dry soils (Agricultural Research Service 1971). *Cardaria draba* Desv. (hoary cress) is a perennial herb typically 10-80 cm tall producing round leaves and terminal inflorescences on a linear stem. It is naturalized from Europe and is often found in a similar habitat as *L. virginicum*, where it grows from June to October (Agricultural Research Service 1971).

Seeds were obtained (F. and J. Seed Service, Woodstock, Ilinois), and planted in 4 inch pots in a seven week greenhouse experiment. In each pot, a focal plant to be harvested and weighed was surrounded by five neighbor plants, either of the same or a different species. In one treatment, all seeds were planted simultaneously. In the second treatment ("delayed"), the focal seed was planted five days later than the seeds of the neighboring plants. There were four identical plantings in the two treatment, yielding a total of eight plantings. The first two plantings dealt with interspecific competition: one with an annual target surrounded by perennial neighbors and another with a perennial target surrounded by annuals. The other two plantings examined intraspecific competition: one with an annual target surrounded by annual neighbors and in the second, a perennial target surrounded by perennial neighbors.

Twelve replicates of each of the eight planting types was used for a total of 96 pots. In two additional pots, extra seedlings of both species were planted. Pro-Mix fine soil mix was used as a planting medium and approximately 4 seeds were planted for each of the six spots available in each pot. The additional seedlings were weeded out one week after germination, and after two weeks, transplants from the two extra pots were planted as necessary to replace missing plants. The pots were kept under strictly natural lighting, were randomly placed on a greenhouse bench, and were randomized twice a week. To maintain a sufficient level of moisture in the soil, the plants were watered twice a day, or as needed, using a misting nozzle. The initial planting was done on 6-13-96, with delayed seeds planted on 6-18-96.

Measurements included the average seed size of both species (each n=20), the average number of days to seedling emergence (each n=7), and seedling mass after 15 days for plants growing singly in 4 inch pots (each n=7).

After seven weeks, the focal plants were harvested. The shoots were cut off at the soil surface with a razor blade and the soil was washed from the roots after extraction from the soil. The plants were dried at 76C for one week, and the individual root and shot biomasses of each plant were determined. The data

BEST COPY AVAILABLE

were analyzed using a three-way analysis of variance, with the target species, neighbor species, and planting date as the main effects.

RESULTS AND DISCUSSION

Due to losses from aphid herbivory, the final sample size of the experiment was 91. Root and shoot biomass, as well as root: shoot mass ratios in both the simultaneous and delayed plantings are shown in Figure 1. At harvest, perennial targets had higher root and shoot biomass than annuals under all simultaneous treatments, with the exception of shoot mass in the intraspecific treatment, in which the two species did not differ significantly. This trend for higher root and shoot mass indicates the perennial's higher allocation to vegetative tissue, as well as its ability to compete well in stable environments regulated by density-dependent effects such as competition from other plants.

For both planting times, the annual performed better, displaying higher shoot mass, in intraspecific plantings while the perennial had its higher shoot mass when grown with the other species. These results are consistent with the theory that the superior competitor will be favored in interspecific plantings, while the inferior competitor will perform best in intraspecific plantings (de Wit 1960).

Results from analysis of variance are given in Table 1. As shown by the significant effect of time on root and shoot growth ($p<0.001$), delayed plants were smaller. In addition, the target*time interaction was significant for root, shoot and ratios ($p<.05$), displaying that delayed seedling emergence has a differential effect on the competitive abilities of the two species. In addition, the neighbor*time interaction was significant for shoots ($p=.005$) and the target*neighbor*time interaction was significant for root: shoot mass ratios ($p=0.034$).

target*neighbor*time	0.969	0.328	1.502	0.224	4.628	0.034

In theory, the perennial would be expected to have a higher root: shoot ratio due to its characteristic high allocation to below ground tissue. However, the effect of delayed seedling emergence skewed this tendency as heavy competition from the mature perennials forced the annual to devote a disproportionate percentage of its resources to roots rather than to shoots. In the simultaneous plantings, the target perennial plants displayed higher root: shoot ratios than did the annuals, but in the delayed plantings, the annuals had higher mass ratios, especially evident in the interspecific treatment. The virtual lack of any shoot growth in the delayed annual showed the amplified effect that delayed seedling emergence had on *L. virginicum* due to space preemption and sunlight blocking by the larger and more mature perennials. In contrast, the delayed *C. draba* had lower root: shoot ratios as they devoted more resources to shoot growth. This is most likely due to the smaller difference in size between the mature neighbor plants and the delayed target plant. Even when delayed by five days, *C. draba* plants were significantly larger than their annual counterparts, a result of their superior competitive ability.

The size dichotomy between *C. draba* and *L. virginicum* indicates that competitive differences between the two species were at least partially rooted in genetic characteristics as well as in differential allocation patterns. The average seed mass of the perennial was 2.348 mg (n=20) and after 15 days, the seedling mass was 7.601 mg (n=7). In contrast, the average mass of *L. virginicum* seeds was 0.351 mg (n=20) and 15-day seedling mass was 2.001 mg (n=7). The competitive superiority of *C. draba* can be explained first, by its characteristically high investment in root growth, allowing it to exploit resources form the soil more effectively, and second, the greater shoot growth of *C. draba*, depleting sunlight and space for not only annual targets, but also those of the same species. Although the size difference between the two species makes it more difficult to attribute competitive differences to differential allocation patterns alone, this experiment simulates nature in that it examines the coexistence of two weeds that are commonly found together in nature, regardless of size. Realistically, competition often occurs between plants of varying sizes.

CONCLUSIONS

This experiment has shown that the perennial may be a superior competitor based on its higher vegetative allocation to roots and shoots. Consistent with this finding, the perennial had its higher shoot mass in interspecific competition while the annual had its higher shoot mass in intraspecific plantings. The effect of delayed seedling emergence was a disadvantage for both species; however, it had an amplified effect on the annual, which displayed very little shoot growth when grown with the competitively dominant perennial.

Self-Incompatibility: a Model for Pollen- and Pollen Tube-Mediated Signal Transduction in *Petunia inflata*

Chandreyee Das

Department of Biochemistry and Molecular Biology

University Park, PA 16802

Faculty Advisor:
Dr. Teh-hui Kao

Self-incompatibility is the mechanism by which an individual plant prevents the fertilization of its female gametes by its own male gametes by recognizing and rejecting self pollen. Although the female component of this recognition reaction is well-studied in *Petunia*, the male (pollen) component has eluded all researchers. In fact, very few pollen-specific genes have been characterized. To contribute to the study of pollen-specific proteins, the expression patterns of two pollen promoters were mapped. The temporal and spatial expression of the Lat52 and PRK1 promoters were tracked by histochemical assay and immunolocalization of the beta-glucuronidase reporter gene fused to each of the two promoters. The Lat52 promoter directed protein expression to the cytoplasm of pollen in stage 3 of floral development and to the placenta of the ovary. The PRK1 promoter showed extremely low levels of expression in the ovary.

BACKGROUND

Sexual reproduction in flowering plants, or angiosperms, is characterized by the fertilization of the female gamete in the ovule by the male gamete in the pollen grain. Pollen grains land on the surface of the stigma, the crown of the long pistil. Pollen germinates by sprouting a pollen tube that grows through the style, the body of the pistil. At the base of the pistil is the ovary containing several ovules which in turn contain the female gametes. The pollen tube grows into the ovary and fertilizes a gamete in an ovule. (Shivanna, 1985)

Hermaphroditic angiosperms produce both pollen and ovules in the same plant, introducing the possibility of male and female gametes from the same individual encountering each other. Inbreeding occurs if an individual plant's male gamete reaches the plant's own ovule and fertilizes the egg inside. The egg itself is unable to distinguish between pollen of different genotypes (Shivanna, 1985). Self-incompatibility is the cell-cell recognition mechanism by which inbreeding is discouraged. To encourage outcrossing and therefore to promote genetic diversity within a population, most self-incompatibility reactions prevent self pollen from germinating into a pollen tube in order to reach the ovule in the ovary (de Nettancourt, 1977). Elucidation of the recognition reaction is important to the signal transduction field and as a model system of maintaining evolutionary fitness of a population.

Self-incompatibility is controlled by one or more polymorphic loci. In most single-locus systems studied, this multiallelic locus is called the S locus, and alleles are called S alleles. Genetically distinct S alleles are numbered to indicate diploid genotypes such as S1S1 (homozygous), S1S2 (heterozygous), S13S13, etc. Homozygous plants carrying a certain S allele are by definition compatible with homozygous plants carrying a different S allele. The product of the S gene, a ribonuclease (McClure et al., 1989), is expressed in the pistil. These S-RNases were first discovered by identifying proteins that co-segrated with S alleles. Pollen-pistil interactions allow the pistil of the recipient plant to recognize the S-genotype of the pollen and either reject or accept the pollen.

BEST COPY AVAILABLE

In sporophytic incompatibility, one of two kinds of self-incompatibility (Figure 1), pollen rejection depends on the genotype of the pollen-producing plant (deNettancourt, 1977). Each pollen grain carries products of both S alleles of the pollen donor. If the either of the pollen donor alleles are the same as those in the pistil, then the pollen is rejected (Newbigin, 1993). Petunia, however, exhibits gametophytic self-incompatibility, in which pollen the product of only one of the two S alleles of the donor plant. If this single allele is the same as either of the recipient plant's alleles, the pollen is rejected.

Figure 1 illustrates the difference between sporophytic and gametophytic self-incompatibility. *Petunia inflata* exhibits the latter, in which incompatible pollen tube growth is arrested in the upper third of the pistil. Compatible pollen germinates freely and the pollen tube reaches the embryo sac in the ovary.

Figure 1: Pollen tube growth in sporophytic and gametophytic self-incompatibility systems. (from Clarke, 1985)

This cell-cell recognition between pollen and pistil depends on the tissue-specific expression of certain gene products. The recipient plant can distinguish between pollen of different genotypes; for example, it may reject S1 pollen but accept S2 pollen. This suggests that the pollen component is polymorphic, with different forms expressed uniquely in pollen of each genotype. To analyze pollen-specific gene expression in petunia, the tissue-specific expression of genes controlled by pollen-specific promoters was mapped.

Signal transduction studies in petunia have been facilitated by the use of pollen promoters such as the LAT52 promoter in transgenic studies. When introducing transgenes into plant tissue, it is necessary to ensure that the promoter directing the transgene's expression is active in the correct tissues to which the transgene is being targeted, and that it is active during the correct stage of development. Mapping the expression patterns of promoters used to drive transgenes is supporting evidence that phenotypic changes in a transgenic plant are truly caused by the transgene and are not artifacts.

The PRK1 protein, a receptor-like kinase in petunia pollen, is thought to be involved in signal transduction. The PRK1 protein has an extracellular domain, a small membrane spanning domain, and a cytoplasmic kinase domain that phosphorylates both serine/threonine and tyrosine residues (Mu et al., 1994). After it was found that PRK1 was most expressed in mature pollen and in in vitro-germinated pollen tubes, the gene was inactivated by transforming petunia plants with the antisense PRK1 gene driven by the LAT52 promoter to determine the function of PRK1 (Lee et al., 1996).

The purpose of this study was to compare the expression patterns of both the LAT52 and PRK1 promoters, within pollen grains as well as in the female tissues of petunia.

LAT52 promoter

In the study of the role of pollen in self incompatibility, the LAT52 promoter from the tomato LAT52 pollen gene has become a popular promoter to use in directing transgene expression to pollen grains. The LAT52 promoter is highly expressed at the start of microspore mitosis in pollen (Twell et al., 1991). LAT52 promoter expression was mapped in tomato tissues by Twell, Yamaguchi and McCormick by fusing the promoter to the b-glucuronidase (GUS) reporter gene in a Ti plasmid and transforming the construct into *Lycopersicon esculentum*. Histochemical assays showed that Lat52 promoter-driven GUS activity was localized in mature anthers and was missing from roots, stems, leaves, sepals, petals, and pistils (Twell et al, 1990). The Lat52 promoter was fused to GUS, was transformed into and mapped in both *Nicotiana alata* and *Arabidopsis thaliana* by Eady et al (Eady et al., 1994), who found no GUS activity in leaves, stems, flowers, or roots. Only pollen showed promoter activity.

Data from LAT52-directed transgenic tomato, tobacco and arabidopsis cannot be applied to petunia without also mapping promoter expression in petunia, because expression patterns of the same gene often vary from one species to another. Lee et al. began studying LAT52 promoter activity in pollen using the LAT52-GUS transgenic plants used in this study. By conducting histochemical assays on the surfaces of both wild type pollen and LAT52-GUS transgenic pollen, they found that approximately 50% of pollen grains had LAT52 promoter-driven GUS activity (Lee et al, 1996). The temporal expression pattern was determined by fluorimetric GUS assay. The LAT52 promoter is active starting with stage 3 of floral development, in which petunia buds are 1.0 to 1.5 cm long.

PRK1 promoter

In comparison to the LAT52 promoter, the PRK1 promoter is much more weakly expressed in pollen. Its activity was immunolocalized to pollen cytoplasm by Dr. Y. Chung (unpublished data). Lee et al. established by RNA blot analysis that PRK1 mRNA first appears in petunia anthers at stage 3, matching the temporal expression pattern of the LAT52 promoter. This stage is that of microspore mitosis. 50% of pollen microspores are aborted in antisense PRK1 plants, indicating that PRK1 plays a role in the signal transduction pathway directing pollen development (Lee et al., 1996).

Antisense PRK1 transgenic plants also exhibit a phenotype affecting the female tissues as well as the male tissues of petunia. For this reason, it was important to make sure that the promoters used to drive PRK1 and its antisense message showed activity in *Petunia* ovaries.

MATERIALS AND METHODS

Transformation of *P. inflata* plants of $S_2 S_3$ genotype with LAT52 and PRK1 promoters fused to GUS reporter gene.

The tomato LAT52 promoter was obtained from Dr. S. McCormick, fused with the GUS reporter gene, cloned into a Ti plasmid, and transformed into *Agrobacterium* by Dr. A. G. McCubbin. The agrobacterium mixture was used to coat petunia leaf strips. Ti plasmid transfer was mediated by tobacco nurse cells. Shoots were grown from transformed leaf strips on kanamycin and carbenicillin selection shoot-inducing MSMO medium (with benzyladenine and a-naphthalene acetic acid growth hormones). Shoots were transferred to root-inducing medium and then to soil. Seven individual plants expressed b-glucuronidase to varying degrees of intensity as measured by Western blot. Transgenic plants containing the PRK1-GUS construct were all prepared by Dr. Y. Chung. One PRK1-GUS plant showed significant GUS activity, as determined by coloригenic GUS substrate assay of PRK1-GUS pollen from a stained anther squashed on a glass slide. The number of blue pollen grains in a random sample of 100 pollen grains was counted for each PRK1-GUS plant.

Histochemical GUS activity assays

Five anthers each from 5 LAT52-GUS transformed *Petunia inflata* buds (developmental stages 1-5) were collected. Bud lengths for each of the five stages were as follows: stage 1, 0-0.5 cm; stage 2, 0.5-1.0 cm; stage 3, 1.0-1.5 cm; stage 4, 1.5-2.0 cm; stage 5, 2.0-2.5 cm. Whole buds in each of these stages and ovaries from stage 5 and open flower were also collected from LAT52-GUS and PRK1-GUS transformants. Anthers, ovaries and whole flowers in each of the 5 stages from wild type S2S2 *Petunia* were used as negative controls for the assays.

Tissues were fixed in formaldehyde (0.23%), mannitol (0.3 M), MES (0.01 M), and fresh phosphate buffer (0.1 M, pH 7.0), washed twice with 100 mM phosphate buffer, and stained overnight. Staining solution contained potassium ferricyanide (0.5 mM), potassium ferrocyanide (0.5 mM), EDTA (0.01 M, pH 8.0), and 1 mM 5-bromo-4-chloro-3-indolylglucuronide (X-Gluc, Jersey Lab Supplies, Livingston, USA). A blue-colored product is the result of cleavage of X-Gluc by GUS.

Sectioning and Light Microscopy

After staining with X-Gluc overnight, the tissues were washed twice with 100 mM phosphate buffer, soaked in 70% ethanol for 15 min., and boiled in 95% ethanol for 10 min. Samples were gradually infiltrated with LR-White™ resin, cast into blocks at 60°C for 6 hrs. and sectioned with an LKB-Bromma ultramicrotome. The 1 μm sections were mounted on poly-L-lysine-coated glass slides, stained for 8 s. in 0.0125% methylene blue, and examined with an Olympus light microscope. Areas of the tissue in which GUS was expressed were stained blue.

Immunolocalization

The activity of the two pollen specific promoters in the ovaries was too weak to be detected by histochemical GUS assay. To pinpoint the subcellular ovary expression patterns of LAT52-GUS and PRK1-GUS promoters, GUS protein was immunolocalized in sections of PRK1-GUS and LAT52-GUS ovaries from stage 4 buds, stage 5 buds and open *Petunia* flowers. Wild type S2S2 ovaries were used as negative controls, and LAT52-GUS stage 4 anther sections were used as positive controls.

Sections prepared as above were first blocked with TBST-BSA (10 mM Tris, 500 mM NaCl, 0.3% Tween 20™, 1% BSA, pH 7.2) for 1.5 hr. Primary anti-GUS antibody (Amersham) was diluted 1:50 with TBST-BSA, incubated at room temperature for 10 min., and placed on the section after blocking for 4 hrs. Sections were washed by shaking and rinsing in TBST-BSA three times for 15 min. each, then incubated 1 hr. with secondary antibody-protein A-gold particle conjugate (AuroProbe EM, Janssen), diluted 1:50 with TBST-BSA. Slides were washed twice for 15 min. each in TBST-BSA, twice with TBST, once 30 min. in dH_2O, and air-dried for at least 10 min.

Silver enhancement of the gold particles was done by mixing 7 drops each of initiator solution and enhancer solution (Amersham International Silver Enhancement kit RPN 491) and placing the mixture on the sections at room temperature for 5 min. The slides were washed in dH_2O, incubated in silver enhancement mixture for another 5 min, washed again, and dried. Light microscopy as described above was used to examine the immunolocalized GUS in each section.

RESULTS

Histochemical GUS assay

GUS was expressed in LAT52-GUS anthers beginning in stage 3 buds. Pollen in stage 3, 4, and 5 anthers were stained blue in approximately equal intensity, while stage 1 and 2 pollen remained colorless. Only the pollen cytoplasm was stained blue in these anthers; GUS was not expressed in the pollen nuclei, vesicles and membranes.

One individual plant transformed with PRK1-GUS was identifed by histochemical GUS assay as having significant GUS activity in the pollen. In a random sample of 100 pollen grains, 22 were stained blue. In comparison, other individual PRK1-GUS plants showed 10 or fewer blue pollen grains in each sample.

Blue color indicating GUS activity was absent in the rest of the buds. The results of histochemical assays of the ovaries were inconclusive, because the blue color was not significantly more intense than in the negative control.

Immunolocalization

In a section of an ovary from a LAT52-GUS transgenic plant in which GUS has been immunolocalized, dark areas where the silver enhanced signal can be seen comprise the placenta of the ovary (Figure 2). The positive control (stage 4 LAT52-GUS pollen sections) exhibited intense silver enhanced signals in the pollen cytoplasm. The negative control (wild type S2S2 ovary showed no silver grains.

A few silver grains were observed in the ovules of PRK1-GUS transgenic plants, but the intensity of the signal was not high enough above background to draw any firm conclusions.

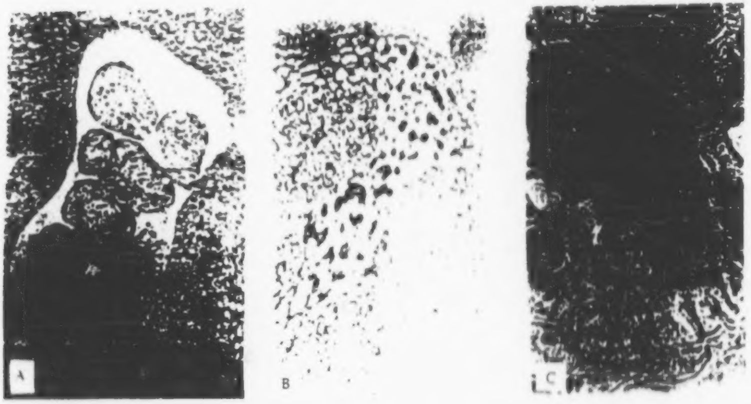

Figure 2: Immunolocalization of GUS with anti-GUS antibody, detected with secondary antibody with protein A-gold particle conjugate followed by silver enhancement. *A)* Immunolocalized section of wild type S2S2 ovary at 10X magnification (negative control). *B)* Section of LAT52-GUS ovary at 10X magnification. Placenta cells show silver enhanced signal, indicating GUS activity. *C)* Section of LAT52-GUS stage 4 anther showing GUS activity in pollen cytoplasm at 32X magnification (positive control).

DISCUSSION

The temporal expression in pollen cytoplasm of the LAT52 promoter corresponded to the pattern previously reported (Lee et al., 1996). The temporal expression in pollen cytoplasm of the LAT52 promoter corresponded to the pattern previously reported (Lee et al., 1996). LAT52-GUS expression coincides with the onset of the self-incompatibility reaction in the pistil; therefore, this promoter is conducive to use in further self-incompatibility research. Further studies must be conducted to determine the implications of LAT52 expression in the placenta of the ovary.

Immunolocalization of PRK1-GUS in ovaries tentatively supports the results of Dr. H.S. et al. (manuscript in preparation, 1997) that the phenotype manifested in antisense PRK1 ovules is indeed caused by inactivation of the PRK1 pollen receptor-like kinase.

The Basidiomycete fungus *Ustilago maydis* causes disease on maize plants when haploid yeast-like cells mate to form the infectious dikaryon. There is evidence that the ability of the cells to mate is cell cycle dependent. One way to better study genes involved in cell cycle regulation is to characterize strains with mutations in their genes. Many of the genes involved in the cell cycle are essential, so our strategy for creating mutants is to screen for conditional mutations in essential genes. Mutants of *U. maydis* were generated by ultraviolet (UV) radiation treatment. Irradiated cells were replica plated at 22°C and 32°C. Cells that could grow at 22°C but not at 32°C have temperature sensitive mutations in essential genes. Over fifteen thousand colonies have been screened, and more than twenty temperature sensitive mutants were isolated. Two mutants were selected for further study. Their mutations were complemented by transformation, and the phenotypes of these mutants were also examined with light and epifluorescence microscopy.

INTRODUCTION

Ustilago maydis, a Basidiomycete fungus, belongs to the order Ustilaginales. This fungus causes a disease of the corn plant *Zea mays*. The infection usually affects the ears of young corn plants and is commonly called 'corn smut.' The characteristics and symptoms include the appearance of yellowing of tissues (chlorosis), production of dark masses of sooty spores that give rise to the name smut, and stunting of the plant (Christensen, 1963).

Ustilago maydis reproduces both sexually and asexually and exhibits three forms during its life cycle: the haploid sporidium, parasitic dikaryotic mycelium and the diploid teliospore. The sporidium form is unicellular, and reproduces by budding like yeast. It is easily grown on solid or liquid media. Like all eukaryotic cells, *U. maydis* must complete the cell cycle in order to reproduce.

Mutagenesis by UV radiation is an effective means of disrupting DNA (Miller, 1972). In order to obtain mutants affected in essential genes, such as those involved in cell cycle events, a strategy involving screening for mutants that are normal when grown under one set of conditions, but unable to grow under other conditions can be used. The most commonly used method involves screening for mutants that can grow at one temperature (the permissive temperature) but not at another (the restrictive temperature).

For effective mutagenesis by UV radiation certain factors must be considered. These include appropriate dosage to acquire maximum and effective kill rate (99-99.9%), appropriate cell density to allow random target and effective penetration of UV radiation to all cells, with resulting random mutations and confirmation of permissive and restrictive temperatures. Holliday (1964) was successful in the production of temperature sensitive auxotrophs, and we have adapted his procedure to seek mutants that have defects in genes involved with the cell cycle.

MATERIALS AND METHODS

The haploid *U. maydis* strain FB2 (Banuett and Herskowitz, 1989) was used for all experiments. Cultures were maintained on Difco Potato Dextrose Agar (PDA) and grown in Difco Potato Dextrose Broth (PDB) for these experiments.

UV mutagenesis -- A 10 ml overnight liquid culture was made and from this a 1:5 dilution using 1 ml of the cell culture and 4 ml sterile PDB was prepared and incubated for an additional 2 hr. The cells were centrifuged and resuspended in 10 ml sterile water. The optical density (OD) at 600 nm was determined and adjusted to 0.11 - 0.12 with sterile water if necessary. Dilutions of 10^{-1}, 10^{-2} and 10^{-3} were plated onto PDA in triplicate to determine the initial colony forming units per ml in the cell suspension. A UV Stratalinker 1800 was used to irradiate 4.0 ml of the cell suspension with ultra-violet light (254 nm). From this irradiated suspension dilutions were prepared as described above (10^{-1}, 10^{-2} and 10^{-3}) to determine the killing rate. The remaining irradiated cell suspension was diluted into PDB and incubated at 28° C with shaking for 2½ hr to allow one generation of growth. Twenty plates of PDA were inoculated with 100 µl of the irradiated cell suspension and incubated at 22° C for 72 hours.

After the 72 hr incubation, the number of colony forming units (CFU) per ml was determined for the suspension both before and after irradiation. The percentage survival was then calculated:

$$\frac{\text{CFU per ml at 78 }\mu\text{J x100\%}}{\text{CFU per ml at 0 }\mu\text{J}}$$

Colonies from suspensions with survival rates of 0.1 - 1% were replica plated onto two PDA plates. One plate from each pair was incubated at 22°C and the other was incubated at 32° C. Colonies which grew at 22° but not at 32° were suspected mutants, and were rescreened. Some temperature sensitive mutants were selected for complementation and further analysis.

Complementation of mutations -- To confirm that the mutant phenotypes resulted from a single mutation, a complementation test was performed. A library of BamHI fragments of wild-type FB2 chromosomal DNA, ligated into a plasmid which can replicate autonomously in *U. maydis*, was used to transform cultures of the mutant cells. Briefly, this involved protoplasting the cells using a chitinase (Novozyme) in an osmotically buffered medium (PDB supplemented with sorbitol). Protoplasts were mixed with aliquots of the wild-type *U. maydis* library on ice. Polyethylene glycol was added to promote uptake of the plasmids into the protoplasts. The transformed protoplasts were then plated onto regeneration medium (PDA plus sorbitol) containing the antibiotic hygromycin to select for transformants.

Transformants in which the plasmid DNA complemented the mutation were either selected directly by incubating the regeneration plates at 32° (the non-permissive temperature) or indirectly by first growing the transformants at 22°C and then incubating replica plates at 32°C. Transformants which were hygromycin resistant and capable of growth at 32°C were further examined to confirm that the plasmid DNA was responsible for the complementation. Transformants were grown for 10 or more generations in PDB without hygromycin. Under these conditions, the plasmid is not stable and is frequently lost (cured) from the cells. Hygromycin sensitive cells were then rescreened for their ability to grow at 32°C. If these cured cells were now temperature sensitive, then the chromosomal DNA in the plasmid did complement the mutation.

Microscopic examination of temperature sensitive mutants --A 10 ml culture of wild-type cells and of each mutant to be studied was prepared and incubated overnight at 22°C with shaking. The cells were then shifted to 32°C. The $O.D._{600}$ of the cultures was determined at 2.5 and 5 hr after transfer to the restrictive temperature. Cells were also stained with the fluorochrome DAPI, which is specific for DNA, and examined microscopically using Differential Interference Microscopy (DIC) and epifluorescence microscopy.

RESULTS

A kill curve was established by exposing cells to different amounts of radiation and then determining the percent survival at each dosage. The dosage which gave the desired survival rate of 0.1-1% was 75-80 µJ. This survival rate was chosen since it typically results in "single hit" mutations and reduces the likelihood of several different mutations occurring in the same cell (Miller, 1974). This dosage of radiation was used for all subsequent experiments. More than 15,000 colonies were screened and 20 temperature sensitive mutants were isolated. Two were selected for complementation and more detailed analysis. These mutants are here referred to as 15-25 and 28-44. Both mutations were complemented using the BamHI genomic library containing wild-type chromosomal DNA from FB2. When the complemented cells were cured of the plasmids the temperature sensitive phenotype was restored.

The effects of the two mutations were examined more closely by growing the cells at the permissive temperature and then transferring them to the restrictive temperature. Cellular and nuclear growth characters were compared with those seen in wild-type (FB2) cells that were treated in the same way.

As seen in Fig. 1, both mutants were extremely reduced in growth rate at 32° C compared with FB2. 28-44 cells doubled once before they stopped growing, and 15-25 cells did not even double before they stopped growth. Mutant 15-25 appeared completely normal at the permissive temperature (Figs. 2-3) but growth stopped quickly at the restrictive temperature. After five hr at the restrictive temperature, most cells were uninucleate and unbudded, or with a small bud (Figs. 4-5). Mutant 28-44 formed multiple buds, and cells remained attached either in clusters or short chains at the permissive temperature (Figs. 6-7). At the restrictive temperature, these cells became multinucleate (Figs. 8-9).

DISCUSSION

The two mutants complemented and described so far are similar in that their mutations are temperature sensitive and recessive, but the phenotypes are quite different. Mutant 15-25 grows normally at the permissive temperature but is unable to form mature buds at the restrictive temperature. The mutation giving rise to such a phenotype could be involved in cell-cycle regulation or with the establishment of cell polarity that is required for bud formation. Alternatively, this mutation could impair some step in metabolism which causes the cells to rapidly halt their growth. At this point it is not possible to speculate further on the exact effect of this mutation.

Mutant 28-44 has a multiple-budding phenotype, even at the permissive temperature. These buds differ from the rare, multiple budded cell observed in wild-type cultures in that the mutant forms multiple buds in a chain or in a stellate pattern at one or both poles. In wild-type cells, multiple buds are rarely observed, and typically consist of only one bud forming at each pole (data not shown). At the permissive temperature, this mutant appears to still regulate karyokinesis with cytokinesis since multinucleate cells were not typically observed (Figs. 6-7). The close link between nuclear division and bud formation is disrupted at the restrictive temperature of 32°C. At this temperature multinucleate cells, often with four or more nuclei, are frequently observed (Figs. 8-9). We believe that in these cells, a protein which links karyokinesis to bud formation is non-functional. The nuclear cycle thus proceeds at a maximal rate, creating new nuclei even though no buds have been formed. Thus, the extra buds formed at 22°C are due to an attempt by the cell to accommodate rapid nuclear proliferation. Alternatively, this mutant could be defective in new bud formation. This would account for both the multiple bud formation at the permissive temperature and the reduced bud formation at the non-permissive temperature. This defect would, however, also require a disruption in the normally tight link between nuclear division and bud formation in *U. maydis*. In another study it was found that wild-type cells must complete the S phase of the cell cycle before bud formation can initiate. If the mutation in this mutant involves bud initiation or positioning, then the multi-nucleate phenotype would also require a disruption of this linkage.

Current investigation of these mutants is focused on an analysis of the DNA fragments from the complementing plasmids. The goal is to define the minimum complementing region, determine its nucleotide sequence and examine any predicted products. Knowledge of these sequences may provide insights into the functions of these gene products through any homologies which they have to proteins of known function in other organisms.

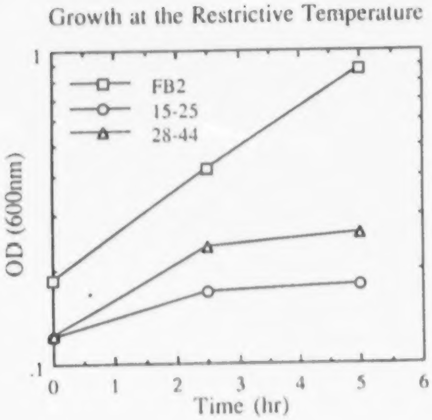

Fig. 1. Growth rate of cells at the non-permissive temperature. Two temperature sensitive mutants (15-25 [o] and 28-44 [Δ]) were grown in PDB at the permissive temperature (22°C) for several generations. The cultures were then shifted to the non-permissive temperature (32°C) and growth was measured by monitoring the optical density (OD) of the culture at 600nm. A culture of the wild-type parent strain, FB2 (❑), was treated similarly for comparison.

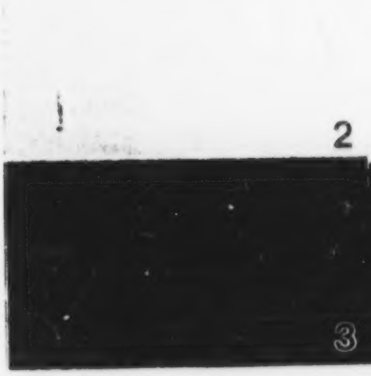

Figs 2-3. DIC (Fig 2) and epifluorescence (Fig 3) of the same field of cells of mutant 15-25 stained with the fluorochrome DAPI immediately after being shifted from 22° to 32°C

Figs 4-5. DIC (Fig 4) and epifluorescence (Fig 5) of the same field of cells of mutant 15-25 stained with the fluorochrome DAPI 5 hr after being shifted from 22° to 32°C. While many of the mutant cells had buds (Fig 4) these buds were smaller than those observed on cells growing at the permissive temperature (Fig 4). The 15-25 cells stop their nuclear cycle when their growth ceases, after 5 hr the cells were uniformly uninucleate (Fig 5).

Figs 6-7. DIC (Fig 6) and epifluorescence (Fig 7) of the same field of cells of mutant 28-44 stained with the fluorochrome DAPI immediately after being shifted from 22° to 32°C. Even when grown at the permissive temperature, large numbers of cells with multiple buds were present (Fig 6)

Figs 8-9. DIC (Fig 8) and epifluorescence (Fig 9) of the same field of cells of mutant 28-44 stained with the fluorochrome DAPI 5 hr after being shifted from 22° to 32°C. Cells with multiple buds are still present (Fig 8) although these cells and buds appear longer and thicker than at the permissive temperature (Fig 6). Frequently cells with many nuclei were observed at this point in the culture (Fig 9).

Putrescine oxidase [PO; E.C. 1.4.3.4] which catalyzes the oxidative deamination of putrescine into γ-aminobutyraldehyde has been partially purified from *Candida guilliermondii*. Among the substrates tested, putrescine has the highest reaction rate followed by spermidine and cadaverine. The K_m values for putrescine, spermidine and cadaverine were 20 μM, 200 μM and 1.1mM, respectively. The optimum pH and the temperature for putrescine oxidase were 8.0 and 37°C, respectively. Growth of *Candida species* on putrescine as the sole nitrogen source induced the synthesis of putrescine oxidase that converts putrescine into Δ'- pyrroline and γ-aminobutyric acid. These two products were detected and identified from the culture medium. The enzyme was not activated by divalent cations. Among the tested species of *Candida*, highest enzyme activity was found in cell-free extracts of *Candida guilliermondii*.

INTRODUCTION

The diamine putrescine (1,4-diamine) and its aminopropyl derivatives, spermidine and spermine, found in various mammalian tissues and many microorganisms, have been implicated a wide variety of biological reactions, including synthesis of deoxyribonucleic acid (DNA), ribonucleic acid (RNA) and protein (Tabor and Tabor, 1976). Specifically, in fungi, spermidine and putrescine have been reported to be important nitrogen sources and regulators of growth (Haywood and Large, 1984, 1985). However, the exact function of the polyamines is not clear. The biosynthesis of these polyamines has been studied and reviewed (Taber and Taber, 1985). Nevertheless, pathways of putrescine degradation in microorganisms have not been surveyed in intricate detail.

Earlier studies indicate that there are two distinct pathways of putrescine degradation (Large, 1992) (Fig.1). In the non-acetylated pathway, putrescine is converted into Δ¹-pyrroline and γ-aminobutyric acid. The Δ¹-pyrroline is then oxidized by either diamine aminotransferase or Δ¹-pyrroline dehydrogenase into 4-aminobutyrate, which is converted to succinate semialdehyde. This compound is subsequently converted into succinate by semialdehyde dehydrogenase. Succinate can then be metabolized by normal cell metabolism (Large, 1992). The other pathway of putrescine degradation, the acetylated pathway, also yields 4-aminobutyrate, which is converted to succinate, but it goes through a different biological reaction. In this pathway, the polyamine is initially acetylated and then undergoes a series of enzymatic reactions, in which the nitrogen atoms are removed by a series of aminotransferases and oxidases. Specifically, in fungi, most of the oxidation is attributed to acetylputrescine oxidase. Finally, the molecule is deacetylated byacetamidobutryrate deacetylase and converted in 4-aminobutyrate. Haywood and Large (1985) reported that putrescine degradation in *Candida boidinii* occurred

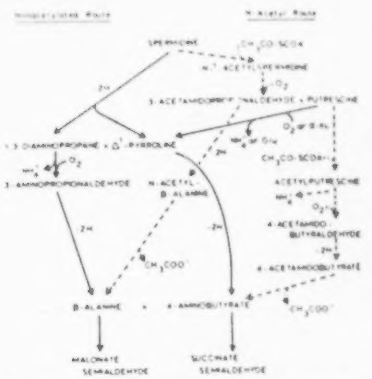

Fig 1. Possible routes for the breakdown of spermidine and putrescine in microorganisms. Broken lines denote the reactions of the *N*-acetyl route

BEST COPY AVAILABLE

through this acetylated pathway. In this report, we show that putrescine degradation in an opportunistic yeast pathogenic to humans, *Candida guillermondii*, occurred by oxidative deamination of putrescine through the non-acetylated pathway. The optimal conditions and properties of partially purified putrescine oxidase are also presented.

MATERIALS AND METHODS

Chemicals:

Chemicals were purchased from Sigma Chemicals Co. St. Louis, Mo. and Aldrich, Wisc. [1-4- ^{14}C] putrescine dihydrochloride (specific activity, 72.50 mCi/mmol) was obtained from New England Nuclear Corporation, Boston, Mass.

Cultural Conditions:

Candida guilliermondii (ATCC #6260) was grown in a liquid medium which contained the following ingredients in grams per liter of deionized water: glucose 20; KH_2PO_4, 3.5; $MgSO_4.7H_2O$, 2.5; $CaCl_2$, 2.5; and biotin 30 µg. The nitrogen source used in various experiments was either ammonium sulphate, 2.5 g, or putrescine chloride, 1.0 g per liter of medium. Flasks (500 ml) containing 100 ml of synthetic medium were stoppered with foam plugs, autoclaved and inoculated with yeast suspension from a 16 hour old culture of *C. guilliermondii*. After incubation for the desired period of time at 37°C in a rotary shaker, the cells were harvested by centrifugation at 7000 x g for 15 minutes. Cells were washed with sterile saline and centrifuged again. Cell pellets were frozen or immediately used for enzyme extraction.

Enzyme extracts:

Crude enzyme preparations were obtained by disrupting cells suspended in 0.01 M potassium phosphate buffer, pH 7.2. Approximately 10 g of glass beads (0.45 to 0.5 mm) were added to 2 g (wet weight) of cells in pre-chilled 50 ml Braun glass homogenizing flasks. Cells were disrupted in a Braun disintegrator (Braun, Melsunger, Germany) using two 30-second bursts with a minute interval between bursts. The temperature of the flask chamber was maintained at approximately 4°C by a continuous flow of carbon dioxide. The disrupted cell mass was centrifuged at 20,000 x g for 20 minutes to remove cell debris, unbroken cells, and glass beads. The supernatant fluid was dialyzed in the cold against 100 volumes of buffer for 18 hours with three changes of buffer. The dialyzed extracts were stored at -20°C. Protein content was measured by the Bradford method using serum albumin as the standard (Bradford, 1976).

Putrescine oxidase (PO) assay:

The release of Δ'-pyrroline from putrescine by cell-free extracts was assayed by modifying the method of Shimizu et al. (1988) for putrescine oxidase. The reaction mixture contained 1.0 ml of 0.2 M Tris-HCl buffer, pH 8.0, 0.5 ml of 20mM putrescine, 0.3 ml of 0.1% O-amino-benzaldehyde and 0.5 ml of enzyme in a total volume of 3.0 ml. The assay was carried out at 37°C with continuous shaking and stopped with 0.5 ml of 50% trichloroacetic acid and 2.0 ml of absolute ethanol. The reaction mixture was filtered and the absorbency of the filtrate was measured at 435 nm. Enzyme activity was expressed as nmoles of Δ'-pyrroline produced per minute per mg of protein.

Enzyme purification:

Putrescine oxidase was partially purified from yeast cells of *Candida guilliermondii* by modifying the method of Yamada (1971) and DeSa (1972). The cells were ground and the enzyme was extracted with 0.01 M phosphate buffer, pH 7.0. The cell free extract was then fractionated with ammonium sulfate (40%-60% saturation). The precipitate was suspended in phosphate buffer and then dialyzed for 48 hours against 4 changes of one liter of phosphate buffer. The dialyzed enzyme was then applied to a DEAE-cellulose column (7x50cm) and equilibrated with phosphate buffer. The enzyme was eluted with 0.1 M phosphate buffer, pH 7.0, containing 0.1M NaCl. The fractions were pooled and concentrated by the addition of ammonium sulfate (70% saturation) and dialyzed again. The dialyzed enzyme was then applied to a DEAE-Sephadex (A-50) column (5.5x 6.5 cm) and equilibrated with phosphate buffer. After removal of impurities, the enzyme was eluted with 0.1 M phosphate buffer, containing 0.3 M NaCl. The fractions were then pooled and concentrated by addition of ammonium sulfate (70% saturation). The enzyme was finally dialyzed for 48 hours against four changes of 5 liters each of 0.01 M phosphate buffer, pH 7.0.

Determination of optimum conditions for PO from *Candida guilliermondii*:

The effect of temperature on PO activity was measured by incubating the reaction mixtures at various temperatures ranging from 15 to 50°C. The effect of pH on enzyme activity was measured by adjusting the pH of the substrate using three types of buffers (Citrate-phosphate, Tris-maleate and glycine-sodium hydroxide) over a pH range from 4 to 9.5 under standard enzyme assay conditions.

Identification of PO reaction products:

Using [1-4- ^{14}C] putrescine, the products of the PO reaction was separated by thin layer chromatography (Haywood and Large, 1985). The reactive spots on the thin layer plates were carefully removed with a razor blade, mixed with liquid scintillation fluid and counted in the ^{14}C channel of Beckman LS 1801 liquid scintillation counter.

All the experiments were repeated at least three times and the mean values are given. Samples were analyzed in duplicates. The assays were reproducible within 10% of the standard deviation of the mean values.

RESULTS AND DISCUSSION

Although their mechanism of action still remains unclear, polyamines are widely regarded as central in the cellular growth process (Tabor and Tabor, 1985). Putrescine, in particular, has been shown to be an important nitrogen source and growth factor in fungi (Tabor and Tabor, 1984). Because of the central role polyamines play in cell proliferation, there have been numerous studies on polyamine synthesis and ornithine decarboxylase, as well as polyamine degradation and polyamine oxidases ((Tabor and Tabor, 1976, 1984, 1985). Only recently, however, have studies been done on putrescine degradation and putrescine oxidase in fungal systems (Haywood and Large, 1984, 1985).

Recent studies have postulated that there are two pathways, namely, acetylated and non-acetylated pathways of putrescine degradation in different organisms. Both pathways finally create 4-aminobutyrate, but through different processes. In most higher eukaryotic organisms, polyamine catabolism has been shown to proceed through the non-acetylated pathway (Large, 1992). Recently, however, studies have shown that putrescine catabolism in two species of *Candida*, *Candida boidinii* and *Candida nagoyaensis*, have occurred through the acetylated pathway (Haywood and Large, 1986). In this study, the pathway of putrescine degradation by putrescine oxidase in *Candida guilliermondii* was studied by using the ^{14}C-labelled putrescine as a substrate and measured the the production of γ-aminobutyric acid (GABA), a product in the non-acetylated pathway. This investigation revealed that putrescine degradation does indeed occur through the non-acetylated pathway. GABA was labelled with ^{14}C and was measured in the culture medium and in cell free extracts of *C. guilliermondii*. The data are presented in Table 1.

Table 1. Isolation of ^{14}C-labelled γ-aminobutyric acid (GABA) from culture medium and cell free extracts of *C. guilliermondii*

Putrescine added:	5 X 10^{6} cpm
Putrescine left in the medium:	2.07 X 10^{6}
Putrescine utilized:	2.93 X 10^{6}
Total counts from cell free extracts:	4.3 X 10^{5}
Counts in GABA:	1.1 X 10^{5}
Total counts from culture filtrates:	20.7 X 10^{5}
Counts in GABA:	8.0 X 10^{5}
Total Counts in GABA:	9.1 X 10^{5}
% Conversion:	18.2

Over half of the putrescine added was utilized by the cells. Nearly twenty percent of the putrescine was converted into GABA. It was interesting to note that there was a much larger count of GABA in the culture filtrate (8 times) as in the cell free extract. This is consistent with other studies in fungi that have reported a similar pathway for putrescine breakdown (Haywood and Large,1986, Yamada, Isobe, and Tani, 1980).

Furthermore, the activity of putrescine oxidase was surveyed in six different *Candida* species, and purified and characterized from *Candida guilliermondii*. The specific activity of putrescine oxidase was measured in six species of *Candida*, *Candida albicans*, *Candida guilliermondii*, *Candida krusei*, *Candida tropicalis*, *Candida parapsilosis*, and *Candida stellatoidea*, and the data are presented in Table 2. The growth of the organisms was predominantly the same; interestingly enough, *Candida guilliermondii* did have strikingly less growth than the other organisms. However, in terms of the specific activity of putrescine oxidase, *C. guilliermondii* did have far greater activity than the other organisms. The activity of *C. tropicalis* was nearly as high as in *C. guilliermondii*; the other four organisms showed significant activities as well. From these data, it seems very possible that putrescine degradation in these other organisms may proceed through the non-acetylated pathway. Further investigation is necessary to confirm this hypothesis.

Table 2. The specific activity of putrescine oxidase from different *Candida* species with putrescine as the substrate.

Organisms	Growth (g)	Specific activity*
Candida albicans	2.65	241
Candida guilliermondii	1.95	409
Candida krusei	2.35	307
Candida tropicalis	2.55	398
Candida parapsilosis	2.45	246
Candida stellatoidea	2.15	125

* Δ'-pyrroline n moles/mg protein

Putrescine oxidase from *C. guilliermondii* was also partially purified and characterized. The optimum pH for enzyme activity was 8.0, and the optimum temperature was 37°C. Again, the data were consistent with previous studies that reported optimum pH and temperature to be in that range (Yamada, Isobe, and Tani, 1980). The M_r of PO from *C. guilliermondii* was determined by gel filtration to be 50, 000 which was also consistent with previous reports in fungi and in higher organisms (Ishizuka, Horinouchi, Beppu, 1993). Prior studies had also reported that divalent cations had served to inhibit enzyme activity. We found that divalent cations had no significant effect on the activity of putrescine oxidase from *C. guilliermondii* (Yamada, Isobe, and Tani, 1980). The substrate specificity was also tested, using five different substrates, putrescine, spermidine, cadaverine, spermine, and histamine. The data are presented in Table 3.

Table 3. Specific activity, amount of oxidation, and K_m, of putrescine oxidase from *Candida guilliermondii*, with different polyamine substrates.

Substrate	Specific Activity*	Percent of Oxidation	Apparent K_m (mM)
Putrescine	407	100	0.02
Spermidine	210	52	0.20
Cadaverine	192	47	1.10
Spermine	7	2	N.D
Histamine	0	0	N.D

* Δ'-pyrroline n moles/mg protein
N.D. = Not determined

The enzyme showed activity with only putrescine, spermidine or cadaverine as a substrate; the activity with putrescine was twice as high as the activity with either spermidine or cadaverine. The K_m values for putrescine, spermidine, and cadaverine were 0.02 mM, 0.20 mM, and 1.10 mM, respectively. Use of spermine and histamine showed no activity. Based on these data, these two polyamines show potential as competitive inhibitors of putrescine oxidase.

The breakdown and utilization of polyamines, such as putrescine, in fungal systems still remains extremely incomplete. Further work needs to be done to better understand the role of polyamines as growth factors and organisms' ability to utilize them.

Paul M. Tefft

Heterodera glycines, the Soybean Cyst Nematode, is a major pest of the soybean crop. Hatching of *H. glycines* eggs occurs spontaneously over a long period of time or more quickly in response to root diffusates from host plants. Little is known about the physiological factors that effect the efficacy of the plant's diffusates on hatching. In order to test the role of macronutrients on host plants, diffusates were collected from plants that were grown hydroponically. Plants were fed a modified Hoagland's solution with different levels of the macronutrients calcium and magnesium. Diffusate from plants treated with moderate levels of calcium hatched more nematodes than plants treated with low or high amounts of calcium. Magnesium treatment did not produce any dosage related effects. The role of photoperiodism was also investigated by treating nematode eggs with diffusates derived from plants grown in 8 hour and 14 hour photoperiods. The plants grown in the short photoperiod hatched fewer eggs than those grown under the long photoperiod. Additionally, hatching of encysted eggs and cyst free eggs treated with cyst fluid and cyst homogenates was less than cyst freed eggs.

INTRODUCTION

The cyst nematode *Heterodera glycines* is a destructive obligate endoparasite of soybean plants. Since there are no lasting means for control of these worms, the range of this parasite is increasing. The control of this organism is difficult because it has a life cycle with several stages that are not accessible for experimentation. Females produce eggs that are either located in external sacs or encysted in their bodies. Those eggs located in the cyst can remain dormant for long periods of time withstanding unfavorable conditions. When exposed to proper stimulation, the eggs are released from diapause and the larvae emerge from the eggs. When the eggs in the cyst are stimulated, permeability of the eggshell increases and trehalose is released. The trehalose concentration is thought to play an important role in maintaining dormancy and protecting against desiccation by regulating water content (Clark and Perry, 1981). When trehalose is released, the water uptake of the juvenile can occur due to the lowering of osmotic stress. Aside from permeability changes, enzymatic changes to the eggshell are necessary for eclosion (Perry, 1989).

Certain substances act as hatching stimulants. Salts of zinc and root diffusate of the soybean plants have been found to increase the permeability of the egg and to cause a greater percentage of hatch. Chelation of the root diffusate by EDTA has been shown to potentiate the response to root diffusates.

Environmental conditions and nutrient status of host plants may play a role in the efficacy of plant diffusates or have a direct role in the development of the nematode within the plant. For this reason, investigation of the effects that photoperiodism and macronutrient deficiency had on the diffusates produced from the roots of host plants were conducted. Photoperiodism may be an important cue in the synchronization of host-parasite life cycles. Exposure of host plants to long photoperiods has been shown to effect the hatching of the closely related potato cyst nematode (Hominick, 1986).

When plants lack certain macronutrients, development and viability are compromised. Two such macronutrients are magnesium and calcium. Magnesium has an effect on the photosynthetic process and its deficiency results in the presence of early maturity, chlorotic, and spotted leaves. Calcium also has an effect on the viability of the plant due to its involvement in photosynthesis and membrane integrity. Plants grown hydroponically were exposed to a wide range of calcium and magnesium prior to the collection of diffusates.

In addition to the host plant influencing the rate of hatching and development of these parasites, the cyst environment may play a role in the establishment and maintenance of diapause. Okada (1978) suggested there were factors in the cyst fluid that inhibited egg hatching in *H. glycines*.

MATERIALS AND METHODS

Nematodes were collected from infested soybean plants (William's var.) grown in a climate controlled greenhouse. The infected soil was sieved (mesh 250 μm) and cysts were collected by hand under a dissecting microscope. Where appropriate, eggs were freed from cysts and stored at ambient temperature in water. Soybean root diffusates were collected from uninfected plants grown in pots of sterile sandy loam soil or hydroponically in one liter containers. Plants were removed from the solutions or soil, rinsed, and placed in small flasks with distilled water. After 24 hours, the volume of the liquid was measured (ml), and the roots were weighed (g). The diffusates were quantified in root gram hour / ml (RGH).

In order to determine the effects of the macronutrients on the efficacy of root diffusates to stimulate hatching of *H. glycines* eggs, soybean plants were grown hydroponically in nutrient solutions with six different dosages of magnesium sulfate (1.25 - 250 μM) and calcium nitrate (1.7 μM-1.7 mM) salts. The anions chosen were already in abundance. Four plants were grown for each treatment until reaching the late reproductive stage at which time root diffusates were collected. Egg hatching was assessed by exposing nematode eggs for two weeks to the various diffusates with and without 3.0 mM EDTA (in order to chelate divalent cations) in small test tubes. All diffusates were calibrated to a final concentration of 2.0 RGH. Solutions were changed three times during the incubation. Three aliquots of eggs were treated with zinc chloride (known hatching agent), with distilled water, and with 3.0 mM EDTA to serve as controls. After two weeks of incubation, the ratio of larvae hatched to eggs was determined for each tube.

It has been speculated that the environmental conditions of host plants may have effects on reproduction in cyst nematodes. To determine the effect that photoperiodism may have on host plant diffusates in stimulating the hatching of *H. glycines* eggs, soybean plants were reared in controlled growth chambers under 8 hr. light/16 hr. dark cycle and 14 hr. light / 10 hr. dark cycle. Fecundity was assessed by inoculating ten potted plants grown under the two light conditions with equal aliquots of eggs from 150 cysts. Plants were grown until flowers appeared and then the total number of nematode cysts was determined for each infected plant. To test the effect of photoperiod on the efficacy of host plant diffusates to induce hatching, root diffusates were obtained from another group of plants grown hydroponically in the two different light regimes. An egg hatching study was then set up to test diffusate from each plant with and without EDTA. Controls consisted of egg aliquots incubated in double distilled water, 3.0 mM $ZnCl_2$, and 3.0 mM EDTA. All controls were run three times. After two weeks of incubation, the ratio of hatched larvae to eggs was determined for each tube.

As a preliminary study to examine the effects of the cyst environment on egg hatching, the hatching of encysted eggs was compared to cyst free eggs. Individual cysts or the eggs from individual cysts were placed in wells of microtiter plates. Hatching was assessed over a two week period and compared. Additionally, fluid was collected from cysts in which hatching occurred and from cysts in which hatching occurred at a low rate. A separate batch of eggs was exposed to this fluid and hatching was assessed. Finally, eggs were exposed to homogenates made from cyst walls in order to see if exposure to the cyst wall affected hatching. Homogenates were tested boiled and unboiled. Data were analyzed by Student's t-test or ANOVA and the $p<0.05$ level was considered significant.

RESULTS

Experiments were done to determine the hatching rate of cysts treated with root diffusate from plants grown with selected concentrations of the macronutrients calcium and magnesium. A total of 24 plants were grown in a magnesium free nutrient solution supplemented with a range of 6 concentrations from 1.25 μM - 250 μM magnesium sulfate. The plants raised with the lowest concentration (1.25 μM) were discarded due to a low survival rate. The root diffusate collected from the remaining 20 plants was used to treat eggs either alone or in combination with EDTA. The hatching percentages ranged from 13.35%-35.7%. The highest percent hatching rate occurred in eggs treated with root diffusate collected from plants treated with 2.5 μM magnesium sulfate. The lowest percent hatching occurred in the eggs treated with a combination of root diffusate and EDTA from plants treated with 2.5 μM Mg. However, there was no dosage related trend in the efficacy of diffusates from plants treated with different levels of magnesium. The root diffusates were collected from a total of 18 out of 24 plants (three from each treatment) that were grown in a range of 5 concentrations of calcium nitrate (17μM - 1.7mM). The diffusates were used to treat eggs either alone or in combination with EDTA. The hatching percentages ranged from 10.26%-34.04%. The lowest percent hatching occurred in eggs treated with root diffusate collected from the plants treated with the complete solution. Percent hatching of eggs treated with root diffusate collected from plants treated with an intermediate amount of calcium was higher than small or large amounts of calcium. Overall, EDTA potentiated the response of eggs to diffusate, Figure 1.

The eggs treated with root diffusate collected from plants grown in the long photoperiod showed an almost equivalent rate of hatching as the water control, even with the addition of EDTA. The percentage hatching was 68.5% for both long photoperiod treatments. In contrast, the percentage of hatching for the eggs treated with root diffusate collected from those plants raised in the short photoperiod were lower. Those eggs treated with root diffusate alone decreased to 48.7% hatching. Eggs treated with both root diffusate and EDTA showed an even lower percent hatch of 38.8%, Figure 2. The mean fecundity of nematodes raised on plants exposed to short photoperiod (89.9 cysts/plant) was significantly higher than nematodes reared on plants exposed to a long photoperiod (144.9 cysts/plant).

Encysted eggs that were incubated for two weeks in double distilled water or in the hatching stimulant zinc hatched less than cyst freed eggs. Cyst freed eggs incubated in double distilled water showed a higher percentage of hatch (13.3%) than encysted eggs (3.9%). The cyst freed eggs hatch at 65% for the zinc treated compared to 35% for the encysted eggs, Figure 3. Eggs were treated with cyst fluid and cyst wall homogenates to see if hatching could be inhibited. Eggs that were treated with cyst fluid and zinc hatched 49% compared to 75% hatching in eggs treated with zinc alone, Figure 4. When cyst wall homogenate was added to eggs, the hatching in water decreased from 48.6% to 35.3% for the unboiled and 25.1% for the boiled homogenates.

DISCUSSION

There seemed to be no dosage related trend in the efficacy of diffusates from plants treated with different levels of magnesium or calcium. However, the diffusates collected from plants grown with an intermediate amount of calcium seemed to increase hatching of the eggs. Since calcium and magnesium play such a pivotal role in the overall physiology of the plant it is difficult to speculate on a mechanism. However, the fact the chelated diffusate causes a potentiated effect obviates a direct role played by the divalent ions in the diffusate. It is known that EDTA increases the permeability of nematode eggshells and this may be what potentiates its effect. The eggs treated with diffusate collected from the plants grown in a long photoperiod had a higher percent hatching than those eggs treated with diffusates collected from plants grown in a short photoperiod. This effect may be mediated by factors released by the host plant and used as an environmental cue to regulate diapause in this parasite.

Synchronizing life cycle with season and host development would increase the reproductive success of this parasite.

Interestingly the number of cysts on plants reared in the short photoperiod was higher compared to plants reared in long photoperiod. These differences in infestation suggest that cues from the host may be influencing the development or success of infection. Experiments are under way to examine the effects of other photoperiod regimes.

Encysted eggs hatched less than eggs that were freed from the cyst. Cyst fluid and homogenates made from cyst walls also decreased the percentage of nematode egg hatch. This could mean that the cyst environment, whether it is the cyst wall or the fluid inside the cyst, may have a role in maintenance of diapause of the eggs.

Coat Protein Analysis of Tomato Mosaic Virus (ToMV)

Victor Huber, Nicole Kimmes, and Jesse Barthel

Department of Biology
Northern State University, Aberdeen, SD 57401

Faculty Advisor Dr. N. Bharathan

ABSTRACT

The coat proteins of tomato mosaic virus (ToMV) belonging to the tobamovirus group were characterized by polyacrylamide gel electrophoresis and Western blot analysis, followed by serological probing. The virus isolate had a major coat protein of about 21,000 daltons and a minor coat protein of about 14,400 daltons, both of which reacted with ToMV-specific antisera in Western blot analysis. ToMV RNA extracted from purified virions and translated in the rabbit reticulocyte lysate (RRL) system using tRNA-mediated biotin labelling (Amersham), produced proteins of various sizes, but only two polypeptides, of about 21,000 and 14,400 daltons, were immunoprecipitated with ToMV-specific antiserum. Dot blot analysis using biotinylated ToMV polyclonal antibody allowed for the detection of the virus in crude plant preparations.

INTRODUCTION

A variety of agricultural crops including tomato (*Lycopersicon esculentum*) are easily infected by tomato mosaic virus (ToMV) (Brunt, 1986). Tomato mosaic virus symptoms are known to be caused by several strains of the tobacco mosaic virus. Most of these strains cause local lesions when inoculated into appropriate test plants (for review see Broadbent, 1976). In the Netherlands, eight distinct strains were identified in tomato, based on symptom expression (Rast, 1975).

Recently, a long, rod-shaped virus was isolated from naturally infected tomato plants exhibiting light green mosaic symptoms (Barthel et al., 1996). The purified virus was extremely stable and the disrupted RNA was highly infectious (Barthel et al., 1996). Crude sap preparations from such tomato plants typically produced local lesions when *Chenopodium quinoa* and *Nicotiana glutinosa* were inoculated with the virus. The virus was classified as a member of the tobamovirus group based upon host range, virus morphology, molecular weight of the coat protein (21,000 daltons), and the approximate size of the genomic RNA (6.2 kilobases) (Barthel et al., 1996).

Although there is no known invertebrate vector (Gibbs, 1977), the virus spreads rapidly under field conditions through routine cultural practices (Broadbent, 1976). ToMV is a stable soil and waterborne RNA virus. Widespread transmission of ToMV has been reported in Red spruce in the eastern United States (Costello et al., 1995), through fog and clouds. In this paper, we report on the expression of tomato mosaic viral genome in the cell-free system. Polyproteins and viral-specific coat proteins were analyzed by Western blot analysis using polyclonal antibody to ToMV.

MATERIALS AND METHODS

Virus purification and SDS-Polyacrylamide gel electrophoresis

The ToMV isolate used in this study was obtained from naturally infected tomato (*Lycopersicon esculentum*) plants from Aberdeen, South Dakota. Virus was subsequently established and propagated in *Nicotiana clevelandii* kept in an environmental growth chamber maintained at 27°C with 16 hour lighting. Virus was purified from *N. clevelandii* as described earlier (Barthel et al., 1996). Proteins were separated by discontinuous SDS-polyacrylamide gel electrophoresis (SDS-PAGE) using 12.5% acrylamide in the resolving gel, according to the method of Laemmli (1970). Prior to loading onto the gel, the purified virus pellet was resuspended in 0.06 M Tris-HCl (10 microliters per gram fresh weight), pH 6.8 and combined with 10% glycerol, 2% sodium dodecyl sulfate (SDS), 5% 2-mercaptoethanol, and 0.00125% bromophenol blue. The samples were heated for five minutes in boiling water. To visualize the coat proteins, a portion of the gel was sliced and stained with coomassie blue. Mid-size molecular weight protein markers ranging in size from

97,400 daltons to 14,400 daltons (Promega Corp., Madison, WI) were also electrophoresed under the same conditions.

Polyclonal antibodies to ToMV were produced in New Zealand white inbred rabbits. Three intramuscular injections were given at six day intervals followed by two intravenous injections at seven day intervals. For each intramuscular injection, 1 mg of purified virus, resuspended in 0.5 ml of 0.01 M phosphate buffer, pH 7.2, were emulsified with 0.5 ml Freunds adjuvant. Serum was collected three weeks after the final intravenous injection.

Western blotting and Serological detection

After electrophoresis, the resolving gel containing the proteins was electroblotted to Hybond ECL (Amersham, IL) nitrocellulose membrane as recommended by the manufacturer with few modifications. Membranes were soaked in distilled water and equilibriated in protein transfer buffer (25 mM Tris, 192 mM glycine, pH 8.3). Electroblotting was performed overnight using a 40 mA current at 4°C. Blots were air dried and stored between sheets of 3 mm paper wrapped in Saran Wrap at 4°C until use. For immunodetection optimum concentrations of primary (1:750) ToMV antibodies and secondary (1:1500) biotinylated ToMV antibodies were used. ToMV secondary antibodies were biotinylated as described by the manufacturer (Amersham, IL). ToMV polyclonal antibodies at a concentration of 1 mg/ml were incubated in biotinylation reagent (supplied by the manufacturer) for one hour. The protein was obtained by eluting the solution through a Sephadex G-25 column in aliquots, and measuring the optical density at 280 nm. The blots were incubated with ToMV primary and biotinylated secondary ToMV antibody at various time intervals. The blots were washed each time in Phosphate buffered saline (PBS), pH 7.5 containing 0.1% (v/v) Tween-20. A 1 microgram/ml solution of preformed streptavidin-horseradish peroxidase conjugate was then added to the membrane and incubated for 1 hour at room temperature. After washing 3 times in PBS-Tween (15 minutes each), horseradish peroxidase activity was observed using the principle of enhanced chemiluminescence (ECL). ECL detection reagents were added and luminography was done using Hyperfilm ECL in Kodak X-OMat cassettes.

RNA purification and *in vitro* translation

Freshly purified virus preparations were dissociated by incubation in RNA dissociation buffer (0.1M Tris-HCl, pH 9.0, 2mM EDTA, 1% SDS) for 10 minutes at 60°C. The preparation was quick cooled in an ice-water bath, phenol was extracted, and the product was precipitated as described elsewhere (Bharathan et al., 1992). Translation of ToMV RNA in the rabbit reticulocyte lysate (RRL) system was performed as described by the manufacturer (Amersham, IL) unless noted otherwise. A standard 50 microliter translation mixture consisted of 4 microliters of translation mix minus lysine, 2 microliters of 2.5M potassium acetate, 1 microliter of 25mM magnesium acetate, 1 microliter of biotin-lys-tRNA and 20 microliters of rabbit reticulocyte lysate. Up to 8 micrograms of ToMV RNA was used in 50 microliters of reaction mixture. The reaction mixtures were incubated at 30°C for 60 minutes, and the reactions were terminated by adding three volumes of protein disruption buffer. The translation products were denatured and analyzed by SDS-PAGE and electroblotted to nitrocellulose membrane as described earlier. The membrane was incubated with preformed streptavidin-HRP conjugate and luminography was performed as described for Western blot analysis.

RESULTS AND DISCUSSION

Coat protein

Semipurified preparations from ToMV infected *N. clevelandii* showed, through use of SDS-PAGE, a major protein band of 21,000 daltons (Fig. 1A, lane 3) and one minor band of 14,400 daltons. Neither of these two proteins was present in similar preparations from healthy plants (Barthel et al., 1996). In ultrapurified virion preparations, a 21,000 dalton protein was identified as being the major protein (Fig. 1A, Lane 1). In addition to the 21,000 coat protein, ToMV RNA may encode for three nonstructural proteins of 30,000, 130,000, and 165,000 daltons (Leonard and Zaitlin, 1982). The *in vitro* translation of ToMV RNA in the present study using the RRL system, stimulated incorporation of HRP conjugated streptavidin into proteins 30-50 fold higher than endogenous controls. The major translation products, as determined through SDS-PAGE, ranged in size from 21,000 daltons to 14,400

BEST COPY AVAILABLE

daltons (Fig 1A. lane 2) The translation products were analyzed by immunoprecipitation. and this confirmed the translation of a 21.000 dalton protein (Fig 1B. lane 1) The translation products were detected due to their ability to react with streptavidin-HRP. which detected the biotinylated lysine present in the translation products Some of these products were similar in size to the proteins seen in coat protein analysis (Fig. 1A. lane 3) The translation products did not reveal the presence of large size nonstructural proteins (Fig 1B. lane 1) Protein bands representing both 21.000 dalton and 14.400 dalton proteins reacted strongly with polyclonal antibodies specific to ToMV in Western blot analysis (Fig 1C. lanes 1.2. and 3) Similar results were observed when dot blot analysis. using crude sap obtained from ToMV infected tobacco plants as well as purified virus. was performed (Fig. 2A. columns b-f. Fig 2B. columns b-g) No reaction was observed with healthy sap preparations (Figs 2A & 2B. column a)

Reducing agents like Dithiothreitol (DTT) are known to promote proteolytic cleavage of viral RNA translation products (Pelham. 1979. Yeh and Gonsalves. 1985) In the present study the aliquots with and without DTT yielded the same translation product profile with no apparent high molecular weight protein (data not shown) Western blot analysis using crude healthy sap and ToMV infected sap showed sensitivity to 10^{-6} dilution of the infected sap There was little or no signal with the healthy sap Thus. in this study. two viral proteins. translated from ToMV RNA. were identified serologically Work is currently being done to construct a genomic map of the viral RNA. and to determine the proteolytic processing pathway of its translation products

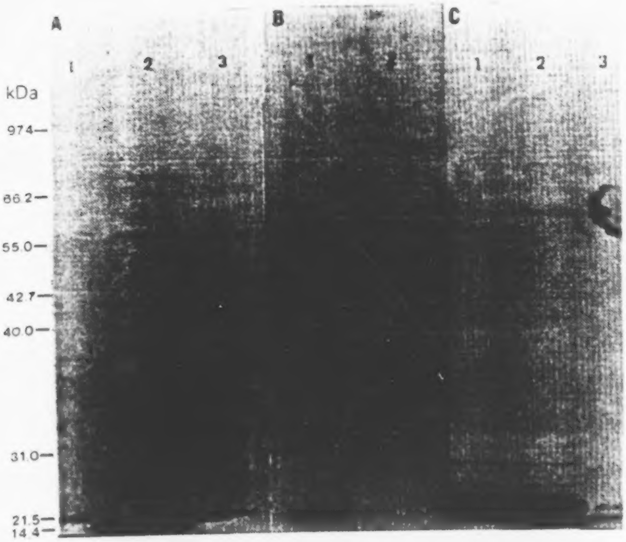

Fig 1 A. **Polyacrylamide gel electrophoresis of ToMV coat protein.** Lane 1 represents the purified viral coat protein. Lane 2 is the *in vitro* translation products from the RRL system and Lane 3 is crude protein from ToMV infected *Nicotiana clevelandii* leaves. The numbers on the left are markers with relative molecular masses in kilodaltons of phosphorylase B, bovine serum albumin, ovalbumin, carbonic anhydrase, soybean trypsin inhibitor, and lysozyme.

B. Analysis of the *in vitro* translation products of tomato mosaic virus RNA using the rabbit reticulocyte lysate (RRL) system with biotinylated tRNA containing lysine. Products were separated by SDS-PAGE and detected by streptavidin-HRP using the principle of enhanced chemiluminescence (ECL). Lane 1 shows the translation products from ToMV RNA. Lane 2 shows the translation products obtained when no ToMV RNA was present during *in vitro* translation.

C. Western blot analysis of crude protein from ToMV infected tobacco plants and of the products of *in vitro* translation. The two samples of crude protein from ToMV infected plants and the sample containing the products from *in vitro* translation, were separated by SDS-PAGE and blotted onto a hybond nitrocellulose membrane as described in the Materials and Methods section. The proteins present on the membrane were precipitated with ToMV secondary antibodies labeled with biotin and detected by streptavidin-HRP using the principle of enhanced chemiluminescence (ECL). Lane 1 and 2 contained the crude protein from ToMV infected tobacco plants. Lane 3 contained the translation products obtained from ToMV RNA using the RRL system.

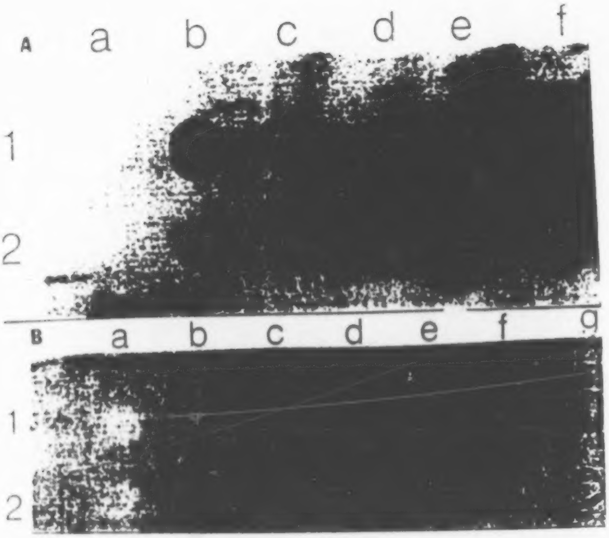

Fig. 2 A. Crude protein from both healthy and ToMV infected tobacco plants were spotted in duplicate onto a hybond nitrocellulose membrane and probed with antibodies to ToMV as described in the Materials and Methods section. Spots 1a and 2a contained crude protein from healthy tobacco plants, where as all other spots: 1b, 2b, 1c, 2c, 1d, 2d, 1e, 2e, 1f, and 2f, contained crude protein from ToMV infected tobacco plants.

B. Crude protein from healthy tobacco plants and purified viral protein isolated from infected tobacco plants was spotted in duplicate onto a hybond nitrocellulose membrane and probed with antibodies to ToMV as described in the Materials and Methods section. Spots 1a and 2a contained crude protein isolated from healthy tobacco plants, where as all other spots: 1b, 2b, 1c, 2c, 1d, 2d, 1e, 2e, 1f, 2f, 1g, and 2g, contained purified ToMV protein isolated from infected tobacco plants.

Feeding Behavior of the Tropical Stick Insect *Extatosoma tiaratum*: A Study in Palatability of Thirty-one North American Plants

Karla J. Johannes

Department of Biology
College of St. Benedict/St. John's University
Collegeville, MN 56321

Faculty Advisor: Dr. James Poff

The feeding behavior of *Extatosoma tiaratum* was studied, with emphases on determination of food preference and the effect of food selection on insect growth and development. Food preference tests established that the insects were generalist feeders, feeding on nineteen species in ten plant families. This represented sixty-one percent of the total plant species tested. Growth and development data suggest that the insects are much more specialized. Although willing to feed on a fairly broad spectrum of plant species, the insects were able to reach full maturity on a much smaller number of plants. Even on plants on which they were able to develop, the insects showed a large variability in weight gain, indicating that not all of the species were equally desirable as feeding substrates.

INTRODUCTION

Feeding behavior is one of the keys to survival in any animal species. It is also one of the major ways in which many animal populations interact with human populations as we compete for limited food and other natural resources. If we are to interact successfully with insects, either in the interests of conservation or control, it is important to understand the mechanisms which regulate their feeding behavior. One of the primary characteristics of the feeding behavior of any species is the width of its feeding spectrum, that is, how varied are the potential foods from which it can successfully extract nutrients.

Extatosoma tiaratum was used as a model system to investigate feeding behavior, especially the process of food selection and how food resource selection affects the growth and development of the organisms. Through previous research these stick insects are known to feed on a few species of eucalyptus in their native Australian habitat (Korboot 1961; Carlberg 1987), while other host plants have been found to be acceptable under laboratory conditions (Carlberg 1987, 1988).

MATERIALS AND METHODS

The feeding behavior of *Extatosoma tiaratum* was studied using a combination of food preference tests and data on growth and mortality. All food plants were obtained locally. A total of thirty-one host plant species from seventeen families were tested. Insects were obtained as eggs and reared in either large plastic cups or hanging netted cages. Insects were fed fresh leaves from their assigned host plant daily and kept at room temperature under ambient light conditions.

Food Preference

Leaves from two different species of plants were placed in a testing arena. Leaves were adjusted to comparable sizes by trimming or including multiple leaflets depending on the species. Insects at various instars reared on various host plants were tested individually for a twenty-four hour period. At the end of the twenty-four hour trial, leaves were scored as either noticeable feeding or no noticeable feeding. The total number of leaves tested was then calculated as well as the number fed upon and not fed upon. The overall percentages of feeding and no feeding from all trials were calculated and used as the expected values in chi-square tests for significance.

Growth and Mortality

As eggs hatched, nymphs were placed ten to a cup on the assigned host plants. Leaves were left with stem intact and placed in testtubes of water to maintain their condition. Leaves were replaced daily and any newly molted individuals were collected and weighed. Weighed insects were placed in a new container. Dead insects were removed. When food plants were no longer available all remaining instars were killed.

BEST COPY AVAILABLE

RESULTS

Food Preference

The food preference results showed significant differences in acceptability. If the insects do show a preference, then it would be expected that some leaves would be fed upon proportionally more and some leaves proportionally less than the average observed in all of the trials. If no preference existed the expected results would show that each species was fed upon the same relative number of times. The chi-square results showed specific species were consumed significantly more times than all other tested species. Some species were fed upon significantly fewer times than all other test species. A few species showed no significant difference. Twelve species were fed upon significantly more often than the other species, seven showed no significant difference and nine were eaten significantly fewer times than the others. These plants were then classified into three groups: completely acceptable, moderately acceptable, and not acceptable (Table 1).

Sumac *Rhus glabra*	<.01				
Walnut *Juglans nigra*	<.01				
White Oak *Quercus alba*	<.01				

Growth and Mortality

Growth data showed that insects raised on Raspberry ultimately weighed more than insects raised on any other plant. Insects fed Raspberry were not, however, invariably the largest. After the first few molts several insects fed on other plants had higher average weights than those fed Raspberry. Average weight gains for insects fed on the three different plant categories (Table 1) are shown in Figure 1. Insects raised on five of the plant species (Basswood, Birch, Ironwood, Raspberry and Red Oak) reached the adult stage. Insects fed on twelve plant species (Ginko, Sugar Maple, Virginia Creeper, Black Locust, Green Ash, Prickly Ash, Wild Grape, Elderberry, Honeysuckle, Gray Poplar, Fern, and Lilac) did not complete the molt to the second instar. Insects survived but did not reach adulthood, within the time period of the experiment, on the eleven remaining plants (Elm, Rose, Pea Shrub, Black Cherry, Hazelnut, Sumac, Gooseberry, Walnut, Willow, White Oak, and Boxelder).

DISCUSSION

Extatosoma tiaratum in captivity feeds on a broad enough variety of plants to be clearly labeled a generalist feeder by several authors' definitions. However, the rearing experiments suggest that the insect is capable of normal growth and development on a much more narrow range of host plants. Based on these results there does not seem to be a strong connection between food plant acceptance rates and insect developmental performance (Figs. 1 & 2). Insects chose species in the food preference experiments that did not result in high survival or growth rates in the growth and mortality experiments. This may be indicative of a historically generalist species on the way to becoming a specialist. In this process the insects

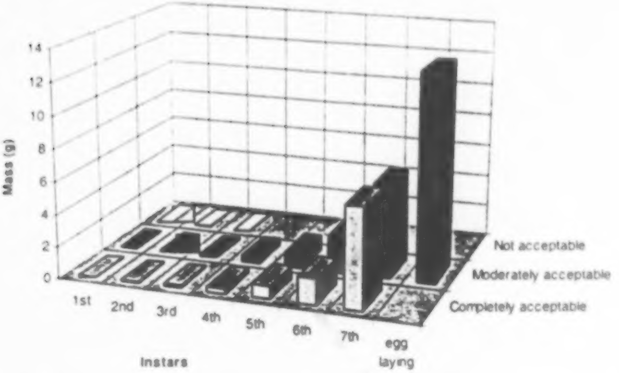

Figure 1: Average Masses (g) of Instars on Host Plants of Different Acceptability Levels (Table 1)

have undergone physiological changes and have lost their ability to successfully feed and survive on many species. However, due to the low diversity of plants other than *Eucalyptus* in their native habitat, the insects have not been under a strong selective pressure to develop an ability to discriminate among various potential food plants.

Knowledge of the acceptability of potential host plants for an insect species will enable future research to focus on why certain plants are chosen over others and the implications of these choices on survival.

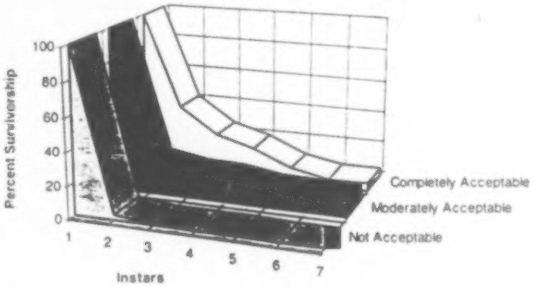

Figure 2: Instar Survivorship on Host Plants of Different Acceptability Levels (Table 1)

ACKNOWLEDGEMENTS

I would like to thank Dr. Poff for introducing me to these fascinating insects and this project. Throughout the project he has offered invaluable advice about procedures as well as continued guidance and support. I also would like to thank the College of St. Benedict and St. John's University for giving me the opportunity to work on this project.

Dr Diane Melroy

Pitcher plants are carnivorous plants which digest insects in large, pitcher-like leaves which fill with rainwater. The plants secrete a variety of digestive enzymes into the pitcher fluid to digest insects. The purpose of this research is to study secretion of the enzyme acid phosphatase into the pitcher fluid.

The pH was determined, and acid phosphatase production was assayed in fed and unfed pitchers. The pH of the pitcher fluid dropped over time in both fed and unfed pitchers. Significant release of acid phosphatase into the pitcher fluid of the fed plants was observed, but little enzyme was released into the unfed pitchers. When EGTA, a calcium chelater, was included in the fed pitcher fluid, there was initially little effect, but by the seventh day after treatment, the pitchers with EGTA had significantly less enzyme activity.

INTRODUCTION

The purple pitcher plant, *Sarracenia purpurea*, is an insectivorous plant found in damp, boggy soils which are deficient in nitrates and phosphates (West, no date). This plant uses nectar glands to attract insects down into its water filled trap. Nectar is produced throughout the plant, but is concentrated around the mouth and veins on the hood (Lloyd, 1942, Joel, 1986). The pitchers can be divided into four regions. The first zone at the outer end of the leaf encompasses the nectar glands which most likely serve to attract insects toward the trap (Cipollini et al., 1994). The second zone is below the first and also contains nectar glands which serve to lure the insects farther down into the plant. Hairs in this region point downward making the footing difficult for the insect. Region three is smooth, and glands in this region produce digestive enzymes. The last region contains hairs which point upward making it difficult for the captured insect to escape.

Once insects are trapped within the fluid filled pitchers, digestive enzymes are released which break them down to release their nutrients. Several different enzymes including chitinase, protease, amylase and acid phosphatase work in combination to break down the insects (Clancy and Coffey, 1977). In this experiment, acid phosphatase was chosen as the enzyme with which to monitor secretion.

Although pitcher plants secrete acid phosphatase, it is difficult to characterize exactly which types of the enzyme are found within the pitchers, and the enzyme was not studied further. The activity that we measured may have been due to one or several enzymes. Since the pH of the pitchers is normally low, acid phosphatase activity was chosen for the assay. The assay yielded p-nitrophenol as the final product. This product was proportionate to the amount of enzyme produced in solution.

The secretion processes of plants, and the ions that are involved, have been the subject of recent experimentation. Much evidence has been found over the past decade which indicates the importance of free calcium ions in the secretion process (Bush, 1993, Poovaiah and Reddy, 1993, Bowler and Chua, 1994, Gilroy and Trewavas, 1994). Through the use of fluorescent calcium sensitive dyes, non-ratiometric dyes, and ratiometric dyes, the levels of calcium ions has been measured in the plant cells (Webb et al., 1996). Just as with animal cells, calcium ions are an integral part of the plant secretion process (Webb et al., 1996). EGTA, a calcium chelater, was used in this experiment to monitor the effects of calcium ion availability and secretion.

MATERIALS AND METHODS

Acid Phosphatase Assay. Two ml of pitcher fluid was put in a test tube, one ml of acid phosphatase buffer was added. Tubes were then incubated at 37 degrees Celsius. After 60 minutes, five ml of 0.1 M NaOH was added to the test tube to stop the reaction. The absorbance was measured on a spectronic 20 spectrophotometer (Clancy and Coffey, 1977).

pH Experiment. Six plants were randomly selected, and their pitchers were rinsed with de-ionized water. Half were randomly chosen for feeding. All live pitchers for each plant were filled with de-ionized water. Those being fed received eight fruit flies (*Drosophila melonogaster*) that were sacrificed by freezing. The initial pH of the de-ionized water was tested before being added to the plants. The pH of the pitcher fluid was determined four and six days after filling.

EGTA Experiment. Twenty-eight pitcher plants were randomly assigned to one of four treatments: (1) water without flies, (2) water with flies, (3) 1.0 mM EGTA without flies, (4) 1.0 mM EGTA with flies. Once the twenty-eight plants were assigned to a group, one from each was randomly assigned to its own block. Thus, there were seven blocks, each of which contained four plants. Three pitchers from each plant were then randomly chosen. The pitchers from each plant were thoroughly rinsed with de-ionized water and filled with their appropriate solutions. Those designated to be fed were given 10 fruit flies each. Two ml of pitcher fluid was assayed for acid phosphatase at daily intervals. After removal of fluid for each daily assay, the pitchers were drained and re-filled with the appropriate solutions. Flies that were removed from the fed pitchers while being drained were replaced so that the total number remained at ten.

The pH was tested using unpaired and paired t-tests. Data for the EGTA experiment were analyzed using repeated measures ANOVA. Block effects were not significant (P=0.15), and the data were reanalyzed to examine the main effects of feeding, EGTA, and their interactions.

RESULTS

pH Experiment. The pH of the de-ionized water added to the pitchers averaged 6.42. The pH of the fluid in the pitchers was determined four and six days after it was added to the pitchers. The average pH of the pitcher fluid for each plant is shown in Table 1.

TABLE 1. The average pH (± 1 SE) of pitcher fluid after four and six days.

Treatment	Four Days	Six Days
fed	4.8 ± 0.09	4.0 ± 0.24
unfed	4.9 ± 0.35	4.6 ± 0.07

Fed and unfed plants did not differ significantly on day 4 (t-test, P=0.73), but were close to significance by day 6 (P=0.056). The solutions in the pitchers became more acidic than the initial solution that was added to the pitchers. After six days, the pH ranged between 3.5 and 4.7.

EGTA Experiment. This experiment was set up as seven blocks, each containing one plant from each of the four treatment groups. Statistical analysis showed that there were no significant block effects, so the data were reanalyzed with the block term removed to increase the error degrees of freedom. Repeated measures ANOVA showed a significant effect of adding flies (P=0.0001), however, the overall effect of EGTA (P=0.43) and the interaction term (P=0.42) were not significant.

A significant increase in enzyme production occurred when flies were added to the pitchers. Those plants that did not receive fruit flies all produced low levels of acid phosphatase throughout the experiment. In the unstimulated plants, the amounts of p-nitrophenol produced were very similar day after day. Since the pitcher fluid was removed and replaced each day, in the absence of stimulation acid phosphatase appears to have been secreted at a constant low rate. When stimulated by flies, there was a lag period of about two days before acid phosphatase began to be secreted at enhanced levels (Figure 1). In this experiment, secretion rates leveled off between four and six days, but then increased again on day seven in the absence of EGTA. In other experiments (data not shown) acid phosphatase secretion peaked earlier, between four and six days after feeding.

Despite the fact that the overall effect of EGTA was not significant, inspection of time trends suggests a strong effect occurring on day 7. We subsequently conducted ANOVAs for each day were conducted significant effects were found for EGTA only on day 7 (P values for days 1-6 range from .46 to .93, P for day 7 = 0.0002).

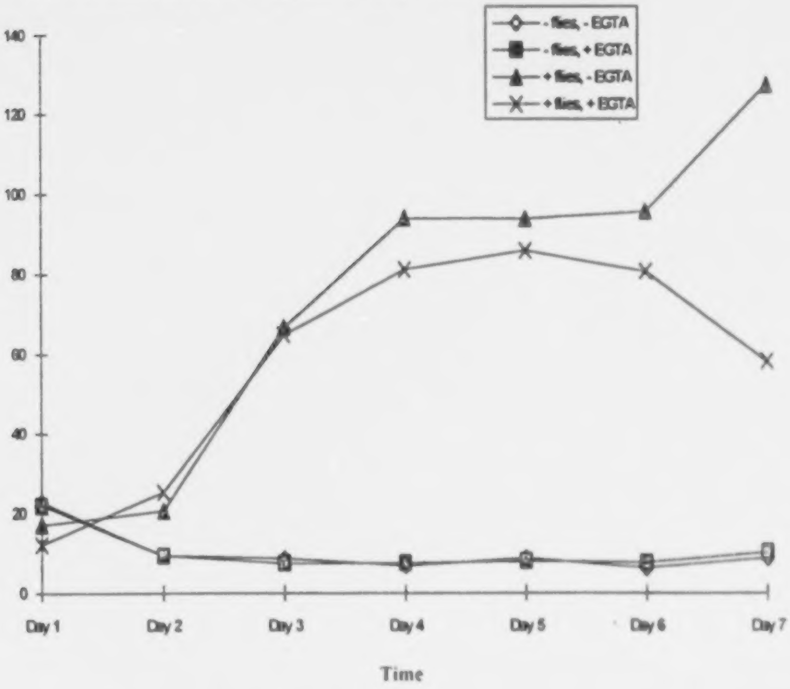

Figure 1 The Average Amount of p-nitrophenol, in nanomoles, produced over Seven Days

DISCUSSION

The pH of the pitcher fluid decreased over time, indicating that the pitcher is an acid environment into which H+ is probably actively secreted by the plant. This has been found by (Tokes et al., 1974). Most species of pitcher plants have pH's that fall between 3.0 and 4.5 (Tokes et al., 1974), and after the sixth day, our pH fell mostly within the expected range. The reason for the low pH may be to keep bacterial growth down. Although yeasts are known to be present in the pitcher fluid, bacteria are not as common, and we seldom noticed turbid pitcher fluid which would indicate excessive bacterial growth.

We found that pitchers have a low acid phosphatase activity when unstimulated, but that the stimulation of having insects in the pitchers increases the amount of acid phosphatase by approximately 5-10 fold. This has been seen in other carnivorous plants as well (Clancy and Coffey, 1977). Since calcium ions are known to be required for most cellular secretion events, we were interested in the role that the calcium ions in pitcher plant secretion. Fed plants treated with EGTA initially showed no difference from fed plants not treated with EGTA, but after seven days, a difference was apparent with treated plants secreting significantly less acid phosphatase. The reason for the delay in the EGTA effect is unknown. It may be that it took seven days for the EGTA presented externally to have an effect on the internal calcium ion concentration.

Elucidating Mechanisms of Pulmonary Fibrosis: Intracelluar and Extracellular Events when the Platelet-derived Growth Factor Receptor System is Up-regulated by Air Pollution Particles and Interleukin 1-beta (IL-1β).

Patricia O. O'Brien

Faculty advisor: Sandra Gilchrist

Man-made particles present in urban areas are associated with increases in several inflammatory lung diseases, including asthma, bronchitis, and pulmonary fibrosis. Air pollution particles were collected from several urban sites in the U.S., Canada, and Mexico. These were tested for their ability to stimulate lung macrophages to release factors that induce the platelet-derived growth factor (PDGF) receptor system on rat lung fibroblasts in a paracrine manner. PDGF is a major mitogen for lung fibroblasts and is important in repairing tissue damage in the lung, but it is also a factor in pulmonary fibroproliferative diseases. Using Western blot analysis of rat lung fibroblast (RLF) PDGF receptors alβha (PDGF-Rα) and beta (PDGF-Rβ), we discovered that the urban particle samples induced macrophages to secrete factors that up-regulated PDGF-Rα; this has been associated with the enhanced proliferation of lung fibroblasts. The PDGF-Rβ was not increased by treatment with macrophage supernatants.

In addition, we studied the role of protein kinase C (PKC), an intracellular second messenger that appears to be involved in the up-regulation of PDGF-Rα on fibroblasts. PKC is activated by interleukin 1-beta (IL-1β), a growth factor or cytokine released by stimulated macrophages. Using cell fractionation and Western blotting techniques on RLFs, we demonstrated that the isozyme PKC alpha (PKC α) is mobilized from the cytosol to the membrane, as soon as 10 minutes after exposure to IL-1β. Determining how the receptor is induced extracellularly and intracellularly could aid in understanding the mechanisms of lung inflammation.

INTRODUCTION

A variety of inhaled agents in the environment can cause lung injury, resulting in an inflammatory response. This inflammatory response may lead to tissue repair which is mediated by cell-derived factors termed growth factors or cytokines. Over-expression of certain cytokines may cause lung fibrosis. Pulmonary fibrosis is characterized by fibroblast proliferation and increased extracellular matrix deposition (1). While bacterial infection, endotoxin, or foreign particles (organic and inorganic) cause lung inflammation, such a response attempts to build a wall around the infection or foreign particles, preventing their spread. However, it is this natural response that causes pulmonary fibrosis and several other inflammatory lung diseases (2).

Alveolar macrophages, immune cells in the lung, release cytokines or growth factors which play a crucial role in the regulation of fibroblast replication. Platelet-derived growth factor (PDGF) and interleukin 1-beta (IL-1β) are released by activated macrophages and stimulate fibroblast mitogenesis (3, 4). PDGF consists of three isoforms made from two polypeptide chains (A and B) which are linked by disulfide bonds, forming AA, AB, and BB dimers. The site for binding is provided by PDGF receptor alpha (PDGF-Rα) and PDGF-R beta (PDGF-Rβ) subunits in the cell membrane. Isoform PDGF-Rββ can only bind PDGF-BB, while PDGF-Rαβ can bind PDGF-AB and -BB. PDGF-Rαα can bind all three isoforms (5). PDGF-Rα is the more sensitive subunit, not just because it can bind both polypeptide chains, but because it induces maximal chemotaxis and mitogenesis (6, 7). In normal rat lung fibroblasts (RLF), the PDGF-Rα is barely expressed, PDGF-Rβ being the sole cell receptor (8). IL-1β causes the up-regulation of PDGF-Rα in lung fibroblasts (7).

Since residual oil fly ash (ROFA), an industrial emission source combustion particle, has been shown to cause fibrosis (9-11), other environmental pollution particles derived from industrial sources may be fibrogenic. We treated rat lung macrophages with air pollution particles *in vitro* and studied the effect of macrophage conditioned media (MØCM) on the rat lung fibroblast receptor system. Induction of the PDGF receptor system was used as a measurement of the fibrogenic potential of air pollution particles.

The major factor that induces PDGF-Rα in MØCM obtained from particle-stimulated macrophages is IL-1β (12). Since IL-1β is an established inducer of PDGF-Rα (7), the role of the second messenger protein kinase C (PKC), a multi-functional enzyme that is specific to certain cell types and cell functions, was examined in rat lung fibroblasts during IL-1β exposure. Certain isozymes, enzyme subunits, have been shown to play a role in cell proliferation. The inactive forms of the isozymes are usually located in the cytosol and are mobilized to the membrane (particulate) when activated, as shown in T-helper type II cells (13), II9 fibroblasts (14), Swiss/3T3 fibroblasts (15), and renal mesangial cells (16).

MATERIALS AND METHODS

Environmental Particle Treatment

Cell Preparation and Membrane Extraction: Rat lung fibroblasts were grown in 10% FBS-DMEM (Fetal Bovine Serum-Dulbecco's Medium) to confluence in 75 cm^2 flasks. The cells were rendered quiescent in SFDM (serum free defined medium) for 24 hours and treated with macrophage conditioned media (MØCM) collected from rat macrophages after a 24 hour exposure to pollution particles. A 0.10 X solution of macrophage medium was made up in 15 ml SFDM, as well as an IL-1β solution (positive control) and SFDM (control) solutions (Table 1). The solutions were removed after 24 hours, and the cells were rinsed with PBS (Phosphate Buffer Solution). To lyse the cells, 250 µl of lysis buffer was added to the flasks which were stored in the cold room (4° C) for 20 minutes. Western analysis was performed on collected samples; the platelet-derived growth factor receptors alpha and beta (PDGF-Rα and PDGF-Rβ) proteins were probed.

PKC Assay

RLFs were prepared as stated above. Examination of the expression or mobilization of PKC α in both cytosol and membrane fraction was performed more exactly by following a cell fractionation protocol (14). Confluent, quiescent fibroblasts in T175 flasks were treated with IL-1β at six time points (0 min, 1 min, 5 min, 10 min, 30 min, 60 min). The same step of washing and aspirating with 15 ml of PBS per flask was performed. To increase the concentration of cells, two 175 cm^2 flasks were used for each time point, collecting a total of 1 ml of lysate (500 µl per flask) for fractionation experiments. One ml of lysate buffer A [25 mM Tris (pH 7.5), 2 mM EDTA, 0.5 mM EGTA, 1 mM DTT, 20 µg/ml leupeptin, 20 µg/ml aprotinin, 1 mM PMSF, and 0.2 mg/ml Triton X 100] was added, and the flasks were rocked for 20 minutes in the cold room. Cells were removed using cell scrapers. A 15 ml dounce homogenizer and pestle was used to homogenize the lysate 10 times. Lysates were centrifuged 100,000 x g for 30 minutes at 4°C in a Beckman TLA 3 fixed angle ultracentrifuge rotor. The supernatant was collected and labeled as the cytosolic fraction. One ml of buffer A supplemented with 10 mg/ml Triton X 100 was added to the remaining pellet. The suspension was sonicated for 5 seconds, rocked for 30 minutes at 4-6°C, and centrifuged at 100,000 x g for 30 minutes. The collected supernatant was labeled as membrane (particulate) fraction. In some cases, a speed vac was used to concentrate the particulate portion with the intention of gaining a stronger signal.

Western analysis was performed on both the cytosolic and particulate fractions using anti-PKC alpha (anti-PKC α). The primary anti-PKC α (1:750) in 3% milk-PBS solution was used for both cytosolic and particulate fractions (15 ml each).

DISCUSSION

Environmental Particle Discussion

In the presence of environmental pollution particles, the platelet-derived growth factor receptor (PDGF-R) system in rat lung fibroblasts is altered, especially for PDGF-R alpha (PDGF-Rα). In Figure 1, an increase in PDGF-Rα expression was observed when macrophage media (MØCM) collected from cells exposed to 10 ng/ml of interleukin 1 beta (IL-1β) and to 0.1X environmental pollution particles from cities in the U.S., Canada, and Mexico (Table 1).. Particles from St. Louis, having a high concentration of pollutive particles (17), had the greatest expression while Washington D.C. particles had the lowest (Table 2). In cities, the levels of pollution are difficult to determine. In general, based on other blots (not shown here), St. Louis and Ottawa city samples tended to induce high levels of PDGF-Rα expression, while Washington D.C. samples fluctuated in their level of expression.

Since there is barely any PDGF-Rα expressed in rat lung fibroblasts, the predominant receptor being PDGF-R beta (β), the up-regulation of PDGF-Rα after environmental particle exposure is significant. Because PDGF-Rα has the capability to bind to both polypeptide subunits of PDGF (A and B), while PDGF-Rβ only binds the B subunit, increasing the expression of such a receptor makes the cells more sensitive to PDGF. In fact, the PDGF-Rα signal elicits a more potent mitogenic response than PDGF-Rβ (7). Therefore, the response to growth factors is more immediate. While there is some variation in the expression of PDGF-Rβ, as shown in Figure 1, it can be inferred that in rat lung fibroblasts the expression of PDGF-Rβ is fairly constant.

PKC Discussion

The role of PKC α mobilization from the cytosol to membrane in PDGF-Rα expression is presently unknown. Using cell fractionation and Western blotting techniques, we showed that the subspecies, or enzyme subunit, PKC α was translocated to the membrane within 10 minutes of exposure, while a stronger signal is seen after 15 minutes (Figure 2). This is interesting because Fitzer-Attas *et al.* have shown that when PKC α is over-expressed in Swiss/3T3 fibroblasts, PDGF-Rα is down-regulated, while PDGF-Rβ remains unaffected (15). In conclusion, PKC α could be regulator of PDGF-Rα expression in rat lung fibroblasts.

Understanding both the extracellular and intracellular events during PDGF-Rα expression, a potent receptor for all isoforms of PDGF, will lead to treatments for pulmonary inflammatory diseases like pulmonary fibrosis.

Tomato spotted wilt virus (TSWV) is the type member of the *Tospovirus* genus, the only plant infecting members of the family Bunyaviridae. TSWV has a host range which includes more than 50 families and agriculturally causes major economic losses. The genomic RNAs of TSWV are encapsidated with multiple copies of a nucleocapsid (N) protein. Viral RNAs must be encapsidated for replication and transcription to occur. Thus, the N protein's RNA binding properties are being characterized to further determine its role in TSWV replication.

The N3 and N4 regions of the nucleocapsid protein along with the entire N protein have been cloned, expressed, and purified. Gel shift mobility assays were performed to determine binding of the ^{32}P labeled single-stranded RNA to full length N, N3, and N4 regions. The N4 region, but not the N3 region, has a binding domain. Also exhibiting RNA binding ability was the full length N protein.

INTRODUCTION

Tomato spotted wilt virus (TSWV) is the type member of the *Tospovirus* genus, the only plant infecting members of the Bunyaviridae family. TSWV has a host range which includes more than 50 different plant families, many important to agriculture. Temperate and tropical regions suffer major economic losses from this virus sometimes losing 50-90% of crops (1).

Several species of thrips (Thysanoptera: Thripidae) transmit TSWV. Thrips acquire *tospoviruses* only while in their larval stage, but remain viruliferous throughout their lives. TSWV likely replicates in the cells of their thrips vectors. Since thrips host range includes many important economic crops, and they have high fecundity and develop pesticide resistance readily, it is of great interest to engineer TSWV resistance in plants.

Bunyaviridae is the largest single family of negative strand viruses. General features which unite this family include a virion structure with a host-derived lipid envelope enclosing three genomic RNAs, each of which is encapsidated with many copies of the nucleocapsid (N) protein. Most members of this family have arthropod vectors and infect vertebrates. Because of the similarities of genomic structure, vector relationships, and virion morphology, information related to the molecular biology of TSWV could be relevant to the formation of control strategies for the entire family, thereby not only improving agriculture, but aiding medicinal science as well.

TSWV's genome includes three segments of negative or ambisense single-stranded RNA with complementary terminal sequences that allow for formation of non-covalently closed circles. Each is coated with many copies of the N protein to form nucleocapsids. The N protein/ RNA complex is vital for RNA replication. It is postulated that the N protein may regulate events in the viral life cycle (2). Two viral glycoproteins (G1 and G2), which are thought to play a role in receptor-mediated

uptake of the virus in its thrips vector, project from the virion surface.

For TSWV, the bacterially expressed full length N protein and its amino- and carboxy- terminal halves have been shown to bind RNA (3). To determine specific binding domains of the protein, quarters of the N protein, approximately 7-8 kDa, are being expressed for use in binding studies. The quarters are referred to as N1, N2, N3, and N4 (Figure 1). The center section composed of N2 and N3 will also be expressed and is referred to as Nmid. The purpose of this research is to characterize the N protein's RNA binding properties to further elucidate its role in TSWV replication. By determining the roles of the N protein, virologists may be better able to subvert infection of TSWV. The hantavirus is the only other member of the Bunyaviridae where the N protein/ RNA complex has been studied.

MATERIALS AND METHODS

Binding Study with the N3 and N4 Regions

Previous attempts by K. Richmond and E. Eyestone (personal communication K. Richmond) to clone the full length N protein, N1, N2, N3, and N4 regions were examined through a process of expression in BL21(DE3) host cells, purification using metal-chelate affinity chromatography, and detection using a 0.1% Coomassie stain and a Western Blot analysis with the N polyclonal antibody. Work was continued with the N3 and N4 regions which had been previously cloned directly into the pET-15b (Novagen) protein expression vector.

K. Richmond and E. Eyestone had transformed the full length N, N1, N2, N3 and N4 pET-15b plasmids into *Esherichia coli* DH5-α non-expression cells to allow for ease in cloning and, then, into *E. coli* BL21(DE3) expression cells. Protein expression was induced with isopropylthio-β-D-galactoside (IPTG) at a final concentration of 1mM in 50 mL of Luria Broth. Bacterial cells were grown in a shaking incubator at 37°C. Time points at 1, 3, and 6 hours were taken after induction of N3 and N4 proteins to monitor expression. Cells were collected four to five hours after induction by centrifugation at 4000xg for 15 minutes in preparation for purification on a Nickel-Nitrilotriacetic acid (Ni-NTA) column.

The pET system carries a sequence of six histidine residues that are expressed at the amino-terminal end of the target protein. The histidine side chains bind with the divalent nickel ions chelated to the NTA resin. A pH gradient can be used to wash and elute proteins off of the Ni-NTA column, since reducing the pH will protonate the amino acid side chains of the histidine residues involved in metal binding (5).

N3 and N4 regions were purified under denaturing conditions. To prepare for column purification, the bacterial cells were suspended in 1 ml Buffer B (8M urea, O.1 M NaH_2PO_4, 0.01 M Tris-HCl, pH 8.0) and set on ice for one hour. The suspension was centrifuged at 10,000 xg for 10 minutes, and the supernatant collected. The Ni-column was pre-equilibrated with 600μl of Buffer B. The column was then loaded with 600μl of the supernatant and spun down for two minutes at 700xg. The column was washed twice with 600μl of Buffer C (8M urea, 0.1M NaH_2PO_4, 0.01M Tris-HCl, pH 6.3), and then eluted twice with 200μl of Buffer E (8M urea, 0.1M NaH_2PO4, 0.01M Tris-HCl, pH 4.5). After each wash and elution, the column was spun at 700 xg for two minutes. Additional time was allowed for any liquid which did not pass through the column after two minutes. Samples were run on a 17.5 % SDS-PAGE stacking gel, and the gel was stained overnight in 0.1% Coomassie blue. Gels were destained with a 5:4:1 mixture of water:methanol:acetic acid. A Western blot analysis was performed with the N polyclonal antibody to indicate that the protein of interest had been eluted.

N3, N4, and the full length N protein were expressed on a larger scale in 175ml of Luria broth and purified on the Ni-NTA column in six fractions. Because previous elution of proteins had background, a more stringent wash (8M urea, 0.1M NaH_2PO_4, 0.01M Tris-HCl, pH 5.9) was added after the initial wash at pH 6.3. The samples were run on a 17.5% SDS- PAGE gel, and the gel was stained overnight in 0.1% Coomassie blue. Protein volumes were reduced using Centricon-3 concentrators (Amicon) which have a molecular weight cutoff of 3 kDa. A Bradford Assay using BSA standards was performed to determine protein concentrations (4).

The binding abilities of the N3 and N4 regions were determined through the use of a gel shift assay. Protein binding can be observed through a shift in mobility of the RNA when it complexes with protein. These complexes can be differentiated through electrophoresis on an agarose gel. Binding reactions consisted of 1μl of ^{32}P labeled single-stranded RNA (1:4 dilution), 0.5μl of RNasin (an RNase inhibitor), 1.5μl of binding buffer (10mM NaCl, 2mM KCl, 5mM $MgCl_2$, 50uM EDTA, 2mM DTT, 25 U RNasin), 1µl volumes of proteins to be assayed for binding and 11µl of sterile water. The N3, N4, and full length N test proteins were estimated to be at a concentration of 0.75µg/µl. Previously expressed full length N protein and the amino-half were used as a positive control. The total reaction volume was brought up to 15µl using diethylpyrocarbonate (DEPC) treated water. DEPC is an inactivator of ribonucleases. The reactions occurred for 45 minutes in a 30°C water bath and products were then loaded onto a 2% agarose gel. The gel ran for two hours at 60V in a horizontal apparatus. The gel was dried onto filter paper and then exposed to X-ray film.

Cloning of the Nmid and N2 regions

Primers designed with restriction enzyme sites *Pst1*, *Nde1*, and *BamH1* (New England Biolabs) were used in PCR amplification of the Nmid region and the N2 region (see Figure 1). PCR products were digested with *Pst1* and *BamH1* restriction enzymes. Initially, digests were run on an agarose gel to determine purity. Appropriate bands were cut from the gels and purified with a Prep-A-Gene kit (Bio-Rad Laboratories).

The Nmid and N2 inserts were then ligated into a vector in 10 µl reactions using T4 DNA ligase. Three vectors were used in three attempts at ligation: 1) pBluescript KS+ (Stratagene) and puc 119, 2) pBluescript KS+ and pET15b, and 3) pBluescript KS+. All vectors exhibit ampicillin resistance. The use of pBluescript KS+ was favored because it is, specifically, a cloning vector and because it has blue/white color selection.

Four attempts were made to transform the subclones into DH5-α *E. coli* competent cells. Controls used in transformations included DH5-α *E. coli* competent cells alone on a 2xYT (yeast, sodium chloride, and triptone) agar plate, competent cells alone on an ampicillin coated 2xYTplate, and undigested vector on an ampicillin coated 2xYT plate.

Selected colonies were grown overnight in 5mL of 2xYT broth at 37°C and purified using alkaline lysis. The selected subclones were then digested with *Nde1* and *BamH1* restriction enzymes. RNase was added to each reaction. The digests were run on an agarose gel to check for the appropriate insert.

RESULTS

Binding Study with the N3 and N4 Regions

Previously cloned N1 and N2 regions (cloned by K. Richmond and E. Eyestone) did not test positive on a Western blot using the N polyclonal antiserum. However, a band was detected for N1 on a 0.1% Coomassie stained 17.5% SDS-PAGE gel. Elution of the expressed full length N, N3, and N4 regions from Ni-NTA columns was confirmed using a Western Blot analysis with the polyclonal N antiserum and a 17.5% SDS-PAGE stacking gel stained in 0.1% Coomassie blue (see Figure 2). Significant background bands were apparent on both the Coomassie stained SDS-PAGE gels and on the Western blots. These bands are believed to be from *E. coli* because the polyclonal N antibody was produced using a recombinant full length N protein in *E. coli* competent cells. The more stringent wash was used in the elution of the full length N protein, N3 and N4 in both the small and large scale expressions to reduce the background bands. The Bradford Assay used to determine the amount of concentrated proteins gave inconsistent results. There were at least two readings taken for each protein at its various concentrations. The values for each concentration were consistent with slight fluctuations (± 2pg/µL). However, the readings for 1µl of concentrated protein varied significantly from those taken for 10µl of concentrated protein. For the binding study, the concentrations of the N3, N4, and full length N protein were assumed to be at 0.75µg/µl.

The RNA binding assay indicates that the N4 region, but not the N3 region, has a binding domain (Figure 3). Binding of N4 to RNA significantly retarded the migration of RNA through the gel. Also exhibiting RNA binding ability were the N proteins from both a previous and recent expression. The amino-terminal half of the N protein has been shown in the past to retard RNA migration (3). Because this was not seen, it would appear that there was an insufficient amount of the amino-terminal half protein added to the binding reaction and, thus, a shift did not occur. Unretarded RNA, apparent on the agarose gel, indicates an imbalance in the ratio of RNA to protein. The concentrations of the proteins determined by the Bradford assay appeared to be overestimated despite the use of the more conservative value.

The results of the gel shift assay support a previous study of two other members of the Bunyaviridae by Gött et al. (1993). The carboxy-terminal domains of Puumala virus strain CG 18-20 (PUU) (aa residues 327 to 433) and Hantaan virus strain 76-118 (HTN) (aa 335-429) were positively identified to bind RNA. These two ends share the highest degree of identity. The amino-terminal domains of PUU and HTN N did not bind RNA at all and share only 53% identity (6). So, it would appear that there is a putative conserved sequence within this region partially responsible for the formation of nucleocapsids.

Cloning of the Nmid and N2 Regions

Nmid and N2 regions were successfully PCR amplified. However, attempts to clone these regions using pBluescript KS+, pET-15b, and puc119 vectors were unsuccessful. All controls, with the exception of the pET-15b undigested, showed that the competent cells and plasmid were good. Analysis of digested DNA collected from certain colonies showed no insert in any of the colonies chosen. Sixty-three colonies were tested. It is possible that the poor recovery of restriction enzyme digested Nmid region using a Prep- A-Gene DNA purification kit created less than optimal ratios of the components of the ligation reactions. Subsequent sequencing of the N2 clone has shown that an additional T was moving the open reading frame out of place (3).

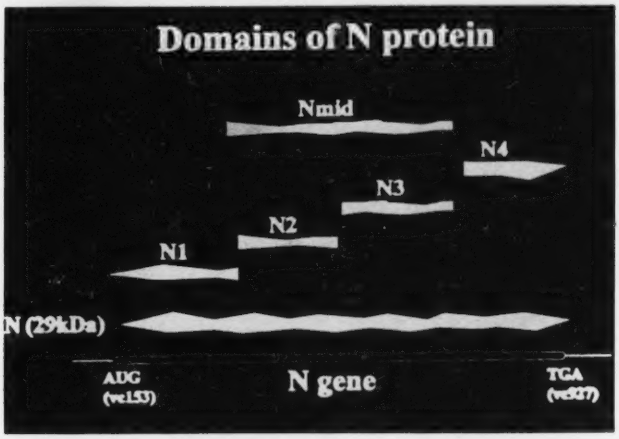

Figure 1. Regions of the nucelocapsid protein which will be expressed and purified for use in gel shift mobility assays.

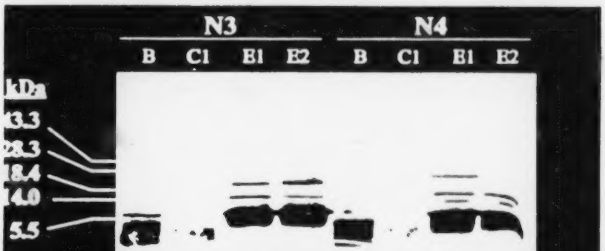

Figure 2. WESTERN BLOT ANALYSIS. Positive identification of eluted N3 and N4 protein regions from Ni-column purification. Fractions below N3 and N4 are as follows: (B) is the flow-through of induced cell lysate, (C1) is the flow-through of wash one of column, (E1/E2) are the elutions of protein from column.

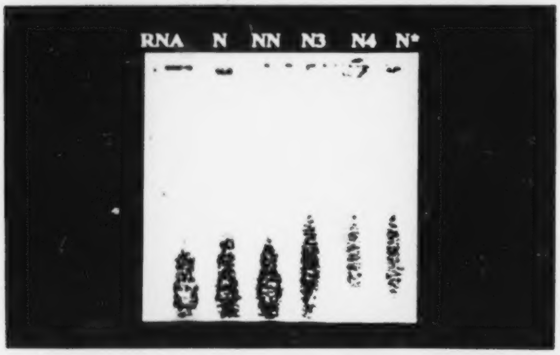

Figure 3. **BINDING ASSAY.** Binding assay reactions were loaded on a 2% agarose gel and electrophoresed for 2 hours at 60V. All lanes contain a single strand ^{32}P labeled RNA with the following additions: Lane (1) water, (2) full length N protein, (3) amino- half of entire N protein, (4) N3 region, (5) N4 region, (6) full length N protein recently expressed.

and Rina Pineda

Department of Biology
Adelphi University
Garden City, NY 11530

Faculty Advisor:
Dr. Lawrence Hobbie

To increase our understanding of the genes controlling plant growth, we are investigating the mechanism of action of the plant hormone auxin using the model plant *Arabidopsis thaliana*. The focus of our investigations is the physiological characterization of the *Arabidopsis* gene *axr5* (auxin-resistant 5). AXR5 is a gene that plays a role in the effects of the plant hormone auxin in *Arabidopsis* plant cells. We have shown that root growth of *axr5* mutant plants is resistant to the natural auxin indole-3-acetic acid (IAA), and that the hypocotyls of dark-grown *axr5* plants are approximately 2 millimeters longer than those of wild-type plants. We also have preliminary results which show that there is no difference in lateral root number between *axr5* mutants and normal, wild-type plants. Further physiological characterization of *axr5* mutant plants will help us to understand the role of the AXR5 gene in the cells of *Arabidopsis* plants.

INTRODUCTION

Auxin is a hormone important for the growth and development of plants. It causes plant cell elongation, division and differentiation (Salisbury and Ross, 1992). Among its many effects, auxin has specifically been shown to be involved in root elongation, lateral bud and root development and internode cell division and elongation (Fosket, 1994). The specific concentration of auxin determines whether these processes are inhibited or promoted. Despite the knowledge of auxin's effects, much remains unknown about this hormone. The mechanism of auxin action remains poorly understood and is of particular interest in this paper.

As in other parts of the plant, the concentration of auxin within the roots determines whether root growth will be inhibited or promoted. At elevated concentrations of exogenous auxin, root growth is inhibited. At least part of this auxin inhibition may be due to the fact that auxin stimulates cells to produce ethylene and ethylene inhibits cell elongation (Salisbury and Ross, 1992). Auxin also plays a role in lateral root development. As the root system develops, side branches grow off the main root. The development of lateral buds is induced by auxin (Fosket,1994). Auxin affects a plant's shoot system as well. The hypocotyl begins right below the point at which the cotyledons (seed leaves) attach and ends at the embryonic root. It is comparable to the stem in mature plants. Auxin also affects this shoot system's growth and development.

Arabidopsis thaliana, commonly referred to as mouse-ear cress, is a useful plant in which to study auxin. It is experimentally a good model organism because it is small, grows quickly, and has a small genome, which makes cloning of genes simple. Also, the knowledge gained in *Arabidopsis* can be applied to other more economically useful plants (Koornneef, 1994).

A genetic approach to the study of auxin was taken in this experiment. Plants with a mutation that disrupts the normal auxin action were analyzed and characterized physiologically and genetically. Physiological characterization involves examination of the mutant plants' structure and comparison to normal, wild-type plants in order to determine differences that may be caused by the mutation. Genetic characterization involves genetic mapping, that is, determination of the exact position of a gene on a chromosome.

BEST COPY AVAILABLE

The *axr5* mutant was isolated in the Estelle lab at Indiana University by Jim Britton and Anna Ruesink (Hobbie, personal communication). The *axr5* (auxin-resistant 5) mutation is defined by one allele. It is a dominant mutation which makes plants resistant to auxin. Genetic analysis has determined the AXR5 gene to be located on chromosome four (Hobbie, unpublished results). Genetic mapping with visible markers has determined the AXR5 gene to be approximately three map units away from HY4 on the short arm of chromosome 4 (Carvan et al., unpublished results).

This paper will focus on the physiological characterization of *axr5* mutant plants. Because of the various effects of auxin, root growth elongation, lateral root formation and hypocotyl elongation of *axr5* mutant plants were studied. Physiological characterization indicates what specific processes the gene is important for. Any physiological difference between mutant plants and wild-type plants suggests that the mutation in the AXR5 gene caused the difference. Thus, the AXR5 gene is necessary for the normal function of that process.

MATERIALS AND METHODS

For all experiments, *Arabidopsis* seedlings were grown on ATS media, containing 0.7% agar, 1.0% sucrose and nutrient solution (Wilson et al., 1990). They were grown in a Percival Scientific growth chamber set on a 16 hour light/ 8 hour dark cycle, at 20^0 Celsius and light intensity of 70-100 µEinstein m^{-2} s^{-1}.

Root Growth Assay

A root growth assay of *axr5* mutant and normal, wild-type seedlings for the following hormones was done - the auxins: indole-3-acetic acid (IAA), 2,4-dichlorophenoxyacetic acid (2,4-D) and others: 6-furfurylaminopurine (kinetin) and abscisic acid (ABA). *axr5* and wild-type seeds were sterilized and spread on ATS plates without hormones, then placed in the growth chamber in the vertical orientation for 4 days. Plates of varying concentrations of the particular hormones were made by adding stock hormone solution to ATS media. Within a laminar hood, 12 *axr5* seedlings and 12 wild-type seedlings were transferred using sterile forceps to each plate containing a specific hormone concentration, and the root tips were marked. The plates were put back in the growth chamber in the vertical orientation for 3 days. The root growth from the point marked was measured in millimeters with a ruler under a dissecting microscope.

Lateral Root Growth

The lateral root growth of *axr5* and wild-type seedlings was studied according to the following procedure. *axr5* and wild-type seedlings were sterilized and spread on ATS plates without hormones. The plates were put into the growth chamber in the vertical orientation for 4 days. Approximately 10 seedlings were transferred to 150 mm petri plates with ATS and the root tips were marked. The plates were returned to the growth chamber in the vertical orientation for 12 days. The lateral roots were counted under a dissecting microscope. A lateral root was described as a sharp outgrowth protruding from the side of the main root.

Hypocotyl Elongation

Characterization of hypocotyl elongation in dark-grown seedlings (etiolation) was done according to the following procedure. *axr5* and wild-type seedlings were sterilized and spread on ATS plates without hormones at 4°C for 2-4 days. The plates were then wrapped in 3 layers of aluminum foil and placed within a cardboard box also covered with aluminum foil to prevent any light from reaching the plates. The covered box was placed in the growth chamber for 7-8 days depending on the experiment. After this time period, the hypocotyls of approximately 60 *axr5* seedling and 60 wild-type seedlings were measured with a metric ruler.

RESULTS

Root Growth Assay

In order to determine the resistance of *axr5* mutant plants to different types of hormones, root growth assays were done. The root growth of *axr5* and wild-type seedlings were compared at various hormone concentrations. In each experiment, the elongation of

BEST COPY AVAILABLE

seedlings on hormone-containing media is expressed relative to the elongation of the same genotype on hormone free media.

The root growth results of IAA, natural auxin, show that as the hormone concentration increases, the percent root elongation decreases (Figure 1a). The results also show that *axr5* is more resistant to IAA than wild-type, and the elongation differences between *axr5* and wild-type at the 10^{-7}, 10^{-6} and 10^{-5} M concentrations are significant.

Similar results were obtained for root growth on the synthetic auxin 2,4-dichlorophenoxyacetic acid (2,4-D) (Fig 1b). The results show that from 10^{-10} to 10^{-6} M concentrations, *axr5* is more resistant to 2,4-D than wild-type. The elongation differences between the two genotypes are significantly large.

The effects of the cytokinin 6-furfurylaminopurine (kinetin) on root growth were also measured. The results show that as kinetin concentration increases, percent elongation generally decreases in both genotypes. The results for the *axr5* mutant were not consistent; in 2 experiments *axr5* was slightly resistant to cytokinin compared to wild-type (Fig 1c) and in a third experiment *axr5* was slightly sensitive to cytokinin compared to wild-type (Fig 1d).

Root growth assay results on abscisic acid (ABA) show that as concentration increases, percent elongation decreases (Fig 1e). The results also show no significant difference in response between *axr5* and wild-type seedlings.

Lateral Root Growth

Preliminary results of lateral root study of *axr5* and wild-type plants shows no significant difference in number of lateral roots (Figure 2). Wild-type plants show an average of 20.2 lateral roots per seedling and *axr5* plants show an average of 21.3 lateral roots per seedling after 16 days growth on hormone-free medium.

Hypocotyl Elongation

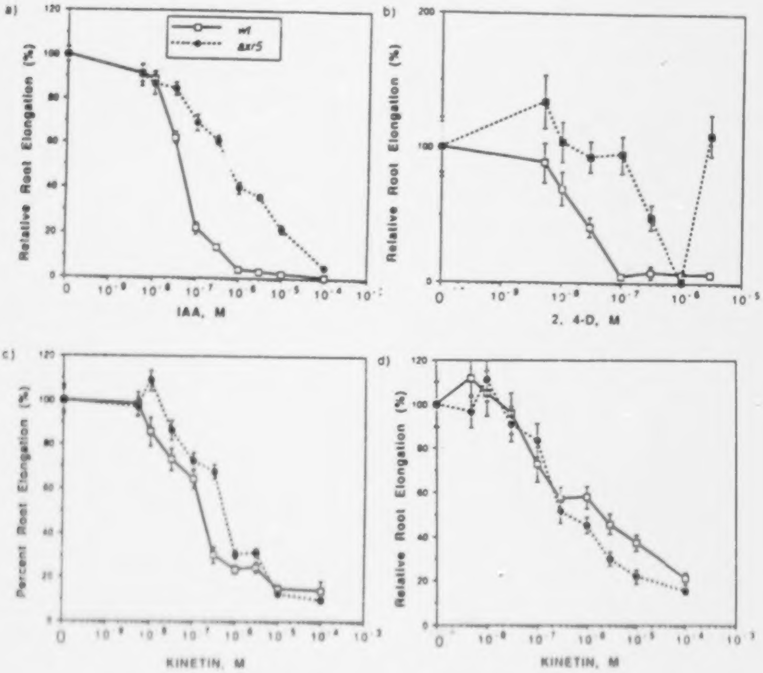
The results of hypocotyl elongation in dark-grown *axr5* and wild-type seedlings show a consistent difference in hypocotyl length (Figure 3). The results of every trial show that *axr5* hypocotyls are significantly longer than wild-type hypocotyls after 7 or 8 days. Anova Single Factor statistical analysis shows p values for the first, second and third trial respectively to be 5.3×10^{-7}, 2.8×10^{-26} and 4.7×10^{-14} with alpha 0.05.

DISCUSSION

Physiological characterization of *axr5* mutant plants shows that the AXR5 gene is important for the plant's response to auxin. Root growth assays show that *axr5* mutant plants are significantly more resistant to the natural auxin IAA and to the synthetic auxin 2,4-D than are wild-type plants. Comparing the concentrations of IAA that reduced root elongation by 50%, about 5×10^{-8} M for wild-type and 7×10^{-7} M for *axr5*, shows that *axr5* is approximately 14 times more resistant to IAA than wild-type. This may indicate that the *axr5* mutation is involved in the signal transduction pathway of auxin in root growth and development. Root growth assays on other classes of hormones, cytokinins and abscisic acid, show no significant difference in root growth elongation between *axr5* and wild-type seedlings. This indicates that the AXR5 gene may be involved in an auxin-specific pathway.

Analysis of lateral root formation showed no significant differences between *axr5* and wild-type plants in number of lateral roots produced after 16 days. This suggests that the AXR5 gene is not involved in the process of lateral root development. However, these results are preliminary so no definite conclusions can be made about lateral roots and the AXR5 gene. Other auxin resistant mutants, such as *axr1*, *aux1*, and *axr4*, all have decreased lateral root production in comparison with wild-type (Hobbie and Estelle, 1995).

The hypocotyl elongation results show a definite difference between hypocotyl elongation in *axr5* and wild-type plants, indicated by the small standard error calculations and the small p values from the Anova statistical analysis. Since other auxin resistant mutants had shorter hypocotyls and *axr5* mutant plants are shorter, the longer *axr5* hypocotyl results were unexpected. They suggest that there may be a defect in the auxin signaling pathway specifically for hypocotyl elongation in *axr5* mutant plants. This defect increases the elongation of hypocotyls, which is very different from other auxin mutants in



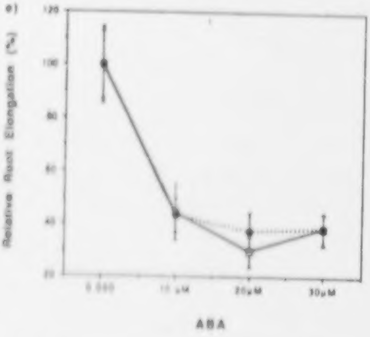


Figure 1. Relative percent root elongation of *axr5* and wild-type seedlings grown on different concentrations of various hormones. a) IAA b) 2,4-D c) kinetin 1 d) kinetin 2 e) ABA. Results based on mean measurements of approximately 10 seedlings at each hormone concentration, +/- the standard error bars shown.

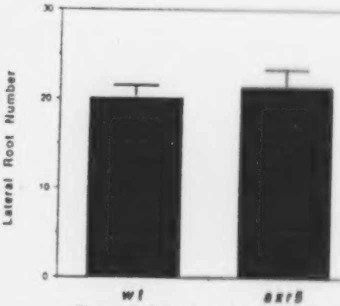

Figure 2. Lateral root number of axr5 and wild-type seedlings.

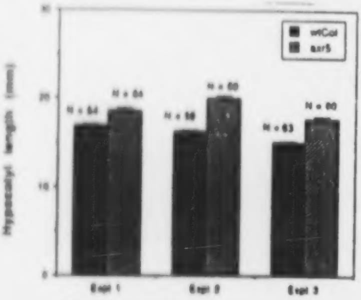

Figure 3. Hypocotyl length of axr5 and wild-type dark-grown seedlings

which hypocotyl elongation is decreased. It is also possible that the brassinosteroid pathway is involved. Hypocotyl etiolation is thought to be controlled by brassinosteroids (Arteca, 1996), and this etiolation difference in *axr5* mutants may indicate some connection between the auxin pathway and the brassinosteroid pathway.

Further physiological characterization of *axr5* plants can add to the information known about the AXR5 gene. Root growth assays on different synthetic auxins, including the benzoic acids, picolinic acids and naphthoxy acids, can be done to further narrow down which auxins *axr5* plants are resistant to. Other classes of hormones, including gibberellins and ethylene, can also be studied for effects on roots of *axr5* seedlings. Extensive lateral root studies should be continued to more accurately quantify the lateral root numbers in *axr5* and wild-type seedlings. Also, hypocotyl elongation could be further studied to determine if brassinosteroids may be involved in the hypocotyl elongation phenotype, perhaps by making double mutants between *axr5* and mutants in the brassinosteroid pathway.

ACKNOWLEDGEMENTS

This project was carried out cooperatively by the 5 authors as part of senior research projects. The authors wish to thank Dr. Hobbie for all his help, guidance and invaluable advice.

Comparison of Microbial Consortia and Environmental Conditions of Two Granite Outcrop Plant Communities

Dr. Sandra T. Bowden

The unique vegetational communities adapted to survival in the rapidly fluctuating environmental conditions of granite outcrops in the southeastern United States have been studied for more than fifty years. These studies include several ecological surveys at Arabia Mountain Nature Preserve, DeKalb County, Georgia. The studies were focused primarily on the surface vegetation, macrofauna, and environmental conditions of distinctive communities that develop as soil accumulates in depressions on the granite. In 1990, Dr. Sandra T. Bowden and Dr. Patricia M. White began an investigation of the microbial communities in the soils of two of the types of plant communities on Arabia Mountain. The two plant communities were designated S for communities with *Sedum smallii* as the only vascular plant represented and AP for communities dominated by mixed annual and perennial herbs and occasional seedlings of woody plants. These two communities are on the same area of the mountain, but they are not connected by water drainage or seepage. They differ in floristic and edaphic characteristics and offer an interesting pair of soil ecosystems in which to explore microbial diversity and environmental factors that may influence microbial biomass and community structure.

We report the results of studies similar to those of Bowden and White that we conducted during 1996-1997. The purpose of this research is to assess local environmental conditions, microbial biomass, and community structure, as well as to provide baseline information for future investigation of the effects of seasonal environmental fluctuations and perturbations on these microbial communities. Our future interests include several basic questions about the general biology and ecology of soil microorganisms–their interactions with each other and with plants, their roles in soil formation and the cycling of nutrients, and the transfer of genes among them.

Traditional microbiological techniques, though valuable in the pursuit of certain types of information, provide a very limited picture of soil microbial communities *in situ*. It has been estimated that only one-tenth of one percent of all microbes living in the soil can be grown as laboratory isolates because of the selective nature of culture media and other cultivation conditions (5). In an effort to study soil microbial communities *in situ* and gain a more accurate picture of their biomass and functional organization, several molecular techniques have been developed, including the use of phospholipid fatty acid profiles, nucleic acid probes, and 16S ribosomal RNA analysis. It has been determined that membrane phospholipids do not persist in the environment following the death of organisms; they are rapidly degraded (7). Therefore, PLFA analysis of whole soil lipid extracts can be used to estimate the biomass and develop a profile of the functional groups of microbes in the soil, determinations that are not possible with classical isolation methods alone.

The total lipid extracted from soil samples is separated into fractions for analysis of the phospholipid fatty acids (PLFA) by capillary gas chromatography and mass spectroscopy (GC-MS). By comparison of these profiles to the distinctive PLFA profiles of organisms with specific physiological characteristics and functional roles in ecosystems, it is possible to infer the presence of representatives of these functional groups of microbes in soil samples that have complex community structure and extremely limited culturability (6). Biomass estimates are based on the total moles % PLFA of a soil sample multiplied by the moles % total PLFA of a microbial cell standard, (one cell of *Escherichia coli*). Whether the microbial communities in the soils of the two plant communities differ in structure can be inferred from cluster analysis of principal component PLFA from extracts of soil samples collected at various times in the same communities and from the profiles of fatty acids that appear to be indicative of the presence of certain groups of microbes in complex communities.

Our general hypothesis is that the soil environments of the two plant communities selected for this research differ in physical and chemical characteristics; therefore, the microbial communities in these soils will differ in biomass and community structure. If the structure and biomass of microbial communities in S and AP soils are different, the PLFA profiles will reflect these differences.

MATERIALS AND METHODS

Environmental measurements: At the field site, soil depth and temperature were measured at regular intervals along a transect running perpendicular to the slope of the outcrop. Air temperature and relative humidity were measured at the time of sample collection. pH was measured electrometrically in slurries of soil with distilled water. Fresh, weighed soil samples oven dried to constant weight at 70°C were used to determine percent moisture; the same dried samples were reduced to ash in a muffle furnace to determine the percent organic content.

Lipid extraction and PLFA analysis: . With sterile technique, 25-gram soil samples were collected, transported to the laboratory on ice, and lyophilized for lipid extraction and PLFA analysis. The total soil lipid extract was prepared by the Bligh and Dyer method (1). The polar phospholipids were separated by solvent fractionation and silicic acid column chromatography (4). Fatty acid methyl esters were derived by mild alkaline methanolysis of the polar lipid fraction to produce fatty acid methyl esters (FAMES) for identification by GC-MS with Hewlett-Packard instruments (2,3,4). Moles percent tables, cluster diagrams, scatter plots, and chromatographs of FAMES were used in the analysis of community structure and biomass. Signature lipids were used comparatively to assess differences in microbial community structure in samples from S and AP communities.

RESULTS

The data from PLFA analysis and environmental measurements are presented in Figure 1 and Tables 1 and 2.

DISCUSSION

In Figure 1, the cluster analysis of PLFA data from samples obtained in 1991 (by another student team) and in 1996 (designated LK and KR samples) reveals strong similarity between principal component fatty acids in sets of AP samples (designated 91AP1 and 2; KR-AP1 and 2). All AP samples show the highest degree of similarity to each other (similarity coefficient=0.55). In contrast, the LK S1 and 2 samples show more similarity to each other than to AP samples (similarity coefficient=0.25), but little similarity to the 91S sample. In summary, with the exception of the 91S sample, which clearly stands apart, the S samples cluster more closely to each other than to AP samples, indicating differences in microbial community structure between S and AP soils. Differences in soil temperature and moisture in the S community between 1991 and 1996 may account for differences in community structure at the time of sampling. It should be noted that if a "control" soil sample from an unrelated plant community had been analyzed by PLFA profile along with S and AP samples, all samples from both S and AP communities very likely would have clustered even more closely.

The 1996 AP community samples contained greater mole percentages of the fatty acids i15:0, cy19:0, 12me16:0, 16:1w5c, 10me16:0, and a17:0, which describe a broad spectrum of organisms, including Gram positive bacteria, actinomycetes, and fungi. The 1996 S community samples contained greater percentages of 18:1w9c, 12me18:0, i17:0, and 24:0, which, when taken as a group, suggest more eukaryotic than prokaryotic influence, with greater involvement of Gram negative bacteria. In summary, 1996 samples from the AP community contain more Gram positive eubacteria and actinomycete members, whereas the 1996 S community appears to contain more Gram negative bacteria, as well as some actinomycetes and eukaryotic microorganisms (7). Therefore, these aspects of the PLFA profiles support the hypothesis that the microbial communities of the two soils differ in structure. The calculated biomass of each of the 1996 S and AP samples may not be significantly different, though the S values were slightly higher than the AP values.

The different environments of the two communities are likely to correlate with variations in microbial community structure. As seen in Table 2, organic content and soil depth differ significantly between the two communities. The average soil temperature (Table 1) and pH (Table 2) were approximately the same for both communities, although the AP community showed a greater range of temperature values, probably due to increased plant cover and soil depth. Moisture percentages varied widely depending on the weather conditions of the sampling day. The differences in depth may affect microbial community structure in part because of a likely soil atmospheric oxidation/reduction potential gradient established by increasing soil depth. For this reason, the AP community may have the ability to support a larger anaerobic component and a greater variety of other microbes. The large discrepancy in organic content between the two soils may also contribute to differences in community structure. The soil of the AP community, with its greater variety of plant life, very likely contains a greater variety of compounds released by living roots and by the decomposition of dead plants. These compounds could enrich the soil and possibly support a microflora different from that of the S community. Also, there may be a correlation between the monotypic flora of the S community and the structure of the soil microbial community beneath it.

Based on the information discussed above, it is reasonable to conclude that the S and AP microbial communities are different in structure in the samples we analyzed, although the microbial biomass of the two soils is similar. Subsequent studies are necessary to determine correlations between specific environmental factors in these two soils and the diversity of the microbial communities within them. Further studies also should investigate the effects of plants, site perturbation, and contamination on the microflora.

ACKNOWLEDGMENTS

We would like to thank Dr. Sandra T. Bowden for her support and enthusiasm, and the Coca-Cola Foundation for funding SHARP! Women, a summer research program for women. We also express appreciation for the contributions of the student investigators who worked on this project during preceding summers, Cynthia Neal, Candace Woodard, and Judy Dudar.

Campus Box 158
Kingsville, Texas 78363

Faculty Advisor:

John C. Pérez

Electrophoretic titration curves were used to determine optimal conditions for the separation of the crude venom (from *Agkistrodon contortrix laticinctus*) with High Performance Liquid Chromatography (HPLC). The optimal pH for hemorrhagic separation was 8.0. The venom was separated by using a Waters HPLC/DEAE column, a 0.02 M Tris-HCl buffer (pH 8.0), and a 0.5 M NaCl Tris-HCl gradient at a pH 8.0; the separation resulted in 9 peaks. A hemorrhagic assay was used to determine the hemorrhagic activity of peaks 5-7 and the specific hemorrhagic activity (0.709, 2.94, and 10.0 respectively) of the purified peaks from crude venom. A minimal hemorrhagic dose (MHD) assay was performed for crude venom and the hemorrhagic fractions obtained from high performance liquid chromatography (HPLC). An antihemorrhagic assay was performed to find the counteracting antihemorrhagic factor(s) involved in blocking the effects of the hemorrhagic factor(s). The antihemorrhagic assay titers for the hemorrhagic peaks were observed to be 8192 for peak 6 and 512 for peak 7. The purified hemorrhagins can used to make monoclonal antibodies and metalloproteinase inhibitors. These antibodies can used in a western blot to compare individual venom protein characteristics from the three subspecies of the Copperheads (*A. c. laticinctus* - the Broad-banded Copperhead, *A. c. contortrix* - the Southern Copperhead, and *A. c. pictigaster* - the Trans-Pecos Copperhead) and aid in the purification of metalloproteinases.

INTRODUCTION

Agkistrodon contortrix laticinctus (the Broad-banded Copperhead) belongs to the family Viperidae and is a relatively docile snake. It can be found in lower-land areas and associated with leaf-covered to wooded terrain throughout central Texas, central Oklahoma, and south-central Kansas. Snake venom has acidic and basic components, with the majority being acidic for *A. c. laticinctus*. Snake venom is also a complex mixture of organic and inorganic molecules which cause hemorrhage, edema and myonecrosis (Schwartz *et al.*, 1984; Tu, 1983). The venom of the Broad-banded Copperhead (*A. c. laticinctus*) is somewhat hemolytic and myotoxic, causing hemorrhage, pain, swelling, breathing difficulty, vomiting, gangrene, necrosis, headaches, and unconsciousness. Despite all of the horrible symptoms, the Broad-banded Copperhead's venom is rather sub-lethal; few people die each year from *A. c. laticinctus* envenomation. However, amputation and loss of function could occur. Snake venoms are different, even for the species as reported by Huang *et al.*, (1992). Martinez et al. (1989) reported geographical variation in venom of snakes from the different species using the enzyme linked immunosorbant assay (ELISA). Adame *et al.* (1990) used three pooled and 20 individual venom samples from different localities in Utah and Arizona to show geographical variation in the antigenicity of the great basin rattlesnake (*Crotalus viridis lutosus*). Anaya *et al.* (1992) reported intrapopulation variation in venom proteins in prairie rattlesnakes (*C. v. viridis*).

It is a purpose of this study to start a comparison analysis between the venoms of three copperhead subspecies (*A. c. laticincts*- the boad-banded copperhead, *A. c.contortrix*- the southern copperhead and *A. c. pictigaster* the trans-pecos copperhead) by HPLC profiles, hemorrhagic and antihemorrhagic assays, and electrophoretic titration curves. Further studies will involve the production of monoclonal antibodies from the hemorrhagic toxins of these copperheads that could be used in the purification of metalloproteinases from these and other snake venoms. Since metalloproteinases are involved in many diseases, there has been interest in designing inhibitors for these proteinases for use as therapeutic agents. Mammalian metalloproteinases are found in low levels (1-10 µg per gram of wet tissue), are difficult to extract and less stable than venom metalloproteinases. The high degree of sequence and structural similarities between snake venom proteinases and mammalian metalloproteinases initiated the use of venom metalloproteinase as models for proteinase inhibitor design (Botos *et al.*, 1996).

MATERIALS AND METHODS

Venom

A. c. laticinctus venom was obtained from three snakes (two female and one male), and maintained at the Biomedical Research Laboratory Serpentarium, Department of Biology, Texas A&M University-Kingsville, Kingsville, TX, USA. The collected venom was stored at -20 °C.

Electrophoretic titration

An electrophoretic titration curve was done using 7.0 µg of *A. c. laticinctus* crude venom with a Pharmacia Phast System with a LKB 3-9 IEF gel. The gel was developed by the development unit - PHASTSYSTEM- Separation and Control Unit and Development Unit (Serial No. 132289; Pharmacia LKB Biotechnology Inc., using silver nitrate as the stain. The electrophoretic titration curve was used to determined the optimal conditions for separation of crude *A. c. laticinctus* venom by HPLC.

Protein separation by anion exchange chromatography

A total of 17.6 mg of crude venom was separated by anion exchange high performance liquid chromatography with a Waters HPLC-Pak DEAE 5PW column (7.5 x 75 mm, part # 088044, Waters Division of Millipore, Millipore Corporation, at a flow rate of 1.0 ml/min for 60 min. Absorbance was measured at 280 nm. Buffers used were 0.02 M Tris-HCl buffer, pH of 8.0 with a 0.5 M NaCl gradient.

Hemorrhagic assay/Minimal hemorrhagic dose (MHD)

A related hemorrhagic assay procedure described by Omari-Satoh *et al.* (1972) was used. Crude *A. c. laticinctus* venom and its fractions were injected intracutaneously into a back of a deiliated rabbit to determine hemorrhagic activity and MHDs (MHD is defined as the amount of protein needed to create a ten millimeter hemorrhagic spot). Crude venom and fractions were diltued to concentrations of 0.150 mg/ml or less. A total of 0.1 ml was injected. The rabbit was sacrificed after 24 hrs and the skin was removed to measure the hemorrhagic spots. The hemorrhagic specific activity was determined by dividing the size of the hemorrhagic spot by the total protein injected. The MHD is determined by the amount of protein needed to produce a 10 mm hemorrhagic spot.

Antihemorrhagic Assay

Two MHDs of the HPLC hemorrhagic fractions were mixed with crude doubling dilutions of opossum serum and incubated at 37°C for 1 hr. One hundred microliters of each of the incubated mixtures were injected into a depilated rabbit. The rabbit was sacrificed after 24 hr and the skin removed. The reciprocal of the highest dilution of serum blocking the minimal hemorrhagic dose was taken as the titer.

RESULTS

Electrophoretic titration curve of crude venom

Figure 1 is an electrophoretic titration curve (ET) of crude *A. c. laticinctus* venom on a IEF 3-9 gel for the Pharmacia PhastSystem. Approximately 10 bands are shown in Figure 1. The IpH of venom proteins and the optimal conditions for HPLC using anion exchange were determined by ET curve. The IpH of each protein is located on the origin of the ET curves. The surface charges (y axis) of the proteins was also determined at different pH. At pH 8.0, most of the proteins in *A. c. laticinctus* venom are negatively charged; suggesting that this particular venom is acidic. The optimal pH for separation in ion exchange chromatography is pH 8.0.

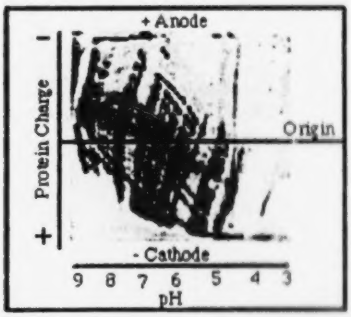

Figure 1. A Pharmacia PhastSystem electrophoretic titration curve of crude *A. c.*

laticinctus venom. A total of 7.0 µg of venom was applied to a 3-9 IEF gel. Silver nitrate was used to stain the gel.

High performance liquid chromatography chromatogram

The chromatogram (Fig. 2) yielded 9 peaks by anion exchange chromatography at pH 8. The hemorrhagic peaks (5-7) eluted from the acidic portion of the ET curve. The specific hemorrhagic activity increases as the negative charge of the proteins increases. Peaks 1 and 2 make up the basic portion of the crude venom and do not have hemorrhagic activity. The other acidic peaks (3-4 and 8-9) were not hemorrhagic. Peak 7 yields the highest specific hemorrhagic activity.

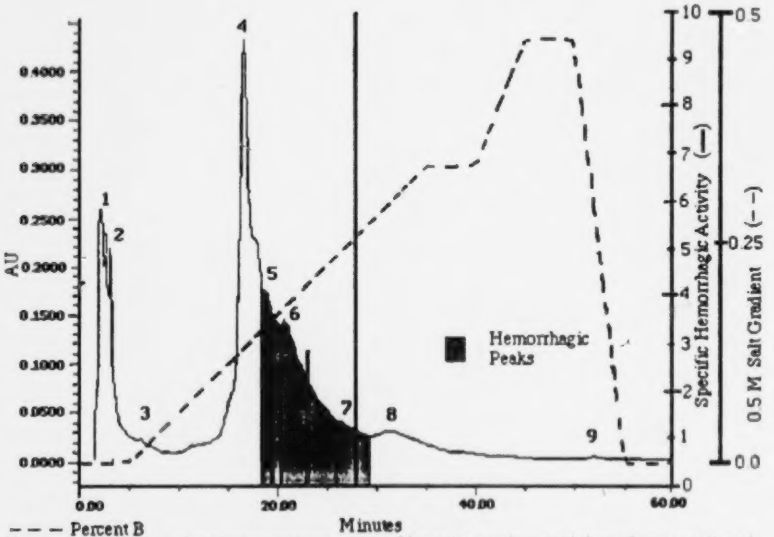

Figure 2. Crude *A. c. laticinctus* venom separated by anion exchange high performance liquid chromatography with a Waters HPLC-Pak DEAE 5PW column (7.5 x 75 mm, part # 088044, Millipore, at a flow rate of 1.0 ml/min for 60 min. The sample injected was 250 µl of a 70.5 mg/ml concentration of crude *A. c. laticinctus* venom and the absorbance was measured at 280 nm. The buffers used were 0.02 M Tris-HCl buffer, pH of 8.0 with a 0.5 M NaCl gradient. Peaks 5-7 were the hemorrhagic peaks.

Hemorrhagic, (MHD), and Antihemorrhagic assay

Table 1 shows the specific hemorrhagic activity of fractinated *A. c. laticinctus* venom. Peaks 1-4 and 8-9 were not hemorrhagic. The specific hemorrhagic activity for peaks 5-7 and crude venom were 0.709 mm/µg, 2.94 mm/µg, 10 mm/µg, and 2.38 mm/µg, respectively. Antihemorrhagic titer from opossum serum obtained for peak 6 and 7 were 8196 and 512 and crude venom titer was 128.

Table 1. Hemorrhagic Activity of *A. c. laticinctus* venom

Peak No.	MHD 1 (µg)	Specific Acitvity (mm/µg) 2	Opossum serum titer 3
1-4	-	-	-
5	14.1	.709	-
6	3.40	2.94	8196
7	1.00	10.0	512
8-9	-	-	-
crude	4.20	2.38	128

1 Minimal Hemorrhagic Dose that causes a 10 mm hemorrhagic spot.
2 The specific hemorrhagic activity calculated by (mm)/total protein injected (µg).
3 The recipricol of the highest dilution of serum (*D. virginiana*) neutralizing the MHD is the titer.

DISCUSSION

Crude *A. c. laticinctus* venom was separated by ET and yielded 10 bands which have IpH ranging between 4 to 9. *A. c. laticinctus* venom has both basic and acidic proteins and could be separated on both an anion and cation exchange column. At pH 6.5, *A. c. laticinctus* venom has the greatest charge distribution, which would be the optimal pH for separating proteins on ion exchange chromatography. Those proteins in a pH environment greater than 6.5 would migrate toward the anode and those with a pH of less than 6.5 migrate to the cathode. In this study a DEAE column was used to fractionate *A. c. laticinctus* venom using a 0.02 M Tris, pH 8 buffer. The reason for selecting pH 8 and DEAE column was for comparison with other venoms which were fractionated at these same conditions.

Nine peaks were observed by HPLC using an anion exchange column. Peaks 5-7 were hemorrhagic and were in the acidic part of the chromatogram in Fig. 2. Peak 7 was the most hemorrhagic peak with a MHD of 1 µg and was neutralized by opossum serum at a dilution titer of 512. The results in this study were consistent with Bjarnason and Tu (1978). *C. atrox* venom has many hemorrhagic toxins (HT) and all have been reported to be acidic proteins. The HT also had metalloproteinase activity. HT-a was the most hemorrhagic but the least proteolytic, which suggests that they may have different affinities for different substrates.

Snake metalloproteinases from venom resemble proteinases in cancer cells (Botos *et al.*, 1996). The metalloproteinase abundantly found in snake venoms can be used to design metalloproteinase inhibitors for cancer cells and neutralize hemorrhage in snakebite victims. Metalloproteinases cause hemorrhage by digesting the cellular matrix around capillaries which allows the blood to escape into the surrounding tissue. A similar process occurs with metastic tumors. Tumor cells penetrate capillaries by metalloproteinase digestion and take up residence in the surrounding tissue. Metalloptroteinases contain zinc in both the cancer cell and snake venom which cleaves through healthy tissue (Botos *et al.*, 1996). An experimental drug, Batimastat, was observed to interact with a metalloproteinase (Ht-d) isolated from the venom of *C. atrox*. The research proved that Batimastat bound to the structure of Ht-d, preventing the metalloprotinease from initiating capillary destruction. The interaction between the venom metalloproteinase and Batimastat gives hope for the design of new drugs that will aid in the fight of pathological conditions such as corneal ulceration, arthritis and cancer. Human metalloproteinases are available; however, snake venom enzymes are useful in the study of such pathological conditions since they are stable, readily available and easily cloned. Therefore, it is essential to purify metalloproteinases from a variety of snake venoms to further understand the mechanism of how these destructive metalloproteinase work. Understanding metalloproteinases will allow the design of new drugs which will fight the war on deadly diseases.

John C. Pérez

The Pacific Mountain rattler, *Crotalus viridis oreganus*, belongs to the family Viperidae. Poisonous snakes such as the *C. v. oreganus* release venom that have hemorrhagic properties. Hemorrhagic proteins break the blood vessels, producing extensive hemorrhaging into the tissue spaces. Yet, certain animals have a natural resistance to poisonous snakes. Hemorrhagins in snake venoms must be purified to study the mechanism of venom neutralization in resistant animals. Electrophoretic titration was used to determine the conditions for ion exchange chromatography of *C.v. oreganus* venom using high performance liquid chromatography (HPLC). The *C. v. oreganus* venom was fractionated into 12 peaks and hemorrhagic activity was measured for each peak and crude venom. Peaks 5-12 exhibited hemorrhagic activity. The most hemorrhagic peaks was 7 and was neutralized by opossum serum. Opossum serum neutralized all hemorrhagic fractions and crude *C. v. oreganus venom.* The objective of this was to purify snake hemorrhagins which can be neutralized by opossum serum. The hemorrhagins will be used to produce monoclonal antibodies which will be useful in studying venom neutralization from different snake species.

INTRODUCTION

Snake venoms are complex mixtures of enzymes and toxins which cause immediate hemorrhage, edema, and myonecrosis (Swartz *et al.*, 1984; Tu, 1983). Each type of snake venom is different. Even within the same species quantitative and qualitative differences can be found between two venoms. There are also many similiarites found in toxins isolated from snakes in different families (Huang *et al.*, 1992, Anaya *et al.*, 1992, and Adame *et al.*, 1990).

Poisonous snakes use their venom for capturing and digesting prey. The envenomated animals suffer from hemorrhaging, swelling, and necrosis which is caused by a variety metalloproteinases. The metalloproteinases in snake venoms are the main contributing factor which cause hemorrhage. McKay *et al.*, (1970) reported that the hemorrhagic toxins (metalloproteinases) disrupt the basement membrane and cause endothelial cell lysis. Many of the venoms in the new world snakes are rich in metalloproteinases.

Even though venom causes medical emergencies in humans, a few warm-blooded animals have a remarkable degree of resistance. Antihemorrhagins are found in the sera of these resistant animals and neutralize a wide variety of hemorrhagins in many snakes (Pérez, *et al.*, 1978b; Catanese and Kress, 1992; and Ovadia *et al*, 1977b). Pérez *et al.* (1978a) reported that gray woodrats (*Neotoma micropus*) were able to withstand 121 times more *C. atrox* venom than white laboratory mice. The North American opossum (*Didelphis virginiana*), Mexican ground squirrel (*Spermophilus mexicanus*), hispid cotton rat (*Sigmodon hispidus*), and the gray woodrat (*Neotoma micropus*) all have a natural resistance to snake envenomation (Kilmon, 1976; Werner and Vick, 1977; and Pérez *et al.*, 1978b). The resistance to hemorrhage in certain animals is the result of antihemorrhagins found in their sera which neutralize hemorrhagins in snake venom nonspecifically.

Soto *et al.*, (1989) reported that the antihemorrhagic activity in sera from resistant animals neutralizes hemorrhagins from different snake venoms. Forty-seven different venoms from the Crotalidae, Viperidae, Elapidae, and Hydrophidae were tested for their hemorrhagic activity. The hemorrhagic activity was found in 80% of the Crotalidae, 50% of the Viperidae, 10% of Elapidae, and none in Hydrophidae venoms tested. Crude opossum and woodrat sera neutralized hemorrhagic activity of all hemorrhagic venoms tested. This is surprising since there are many hemorrhagins in a single venom. All hemorrhagins (seven) from western diamondback rattlesnakes (*C. atrox*) are neutralized by antihemorrhagins found in opossum (*Didelphis virginiana)* sera (Soto *et. al*, 1989). Recently four other hemorrhagic toxin genes from *C. atrox* (Ht-a, Ht-b, Ht-c, and Ht-d) have been cloned and sequenced and shown to share significant homology with Ht-e (Hite *et al.*, 1992b). This information suggests a common epitope theory. If opossum serum neutralizes all hemorrhagin then there must be a common sequence on snake venom hemorrhagins which are recognized by antihemorrhagins found in opossum serum.

BEST COPY AVAILABLE

Monoclonal antibodies were used to study the antigenic nature of venoms (Normura *et al.*, 1982). Martinez*et al.* (1989) produced a monoclonal antibody (CA-P-8) from a hemorrhagic peak 8 of *Crotalus atrox* venom. The CA-P-8 monoclonal antibody completely neutralized hemorrhagic HPLC fractions 6, 7 and 8 from *C. atrox* venom. Crude venoms of *C. adamanteus*, *C. scutulatus scutulatus* and *C. virids lutosus* cross reacted with CA-P-8 via an *enzyme*-linked immunosorbent assay (ELISA). This study showed that these venoms share common epitopes, and therefore; are antigenically related.

Not all hemorrhagic toxins are antigenically related since hemorrhagic fractions 10 and 15 from *C. atrox* venom did not react with CA-P-8. Therefore, it is necessary to produce a panel of antibodies which would be useful in identifying cross-reacting antigens from venoms of different species and venoms of the same species, but from different geographical locations. The purpose of this study is to purify *C. v. oreganus* hemorrhagins which are neutralized by opossum serum. The purified hemorrhagins will be used to produce monoclonal antibodies needed to further study the mechanism of venom neutralization.

METHODS AND MATERIALS

Venom

C. v. oreganus venom was obtained from a snake captured in Washington and housed in the serpentarium at Texas A&M University-Kingsville. Crude venom was stored at -90 °C until used. Crude venom was diluted to 35.5 mg/ml with a 0.02 M Tris-HCl buffer, pH 8.0. The venom solution was centrifuged (Beckman Instruments, Inc., Avanti™30 centrifuge) for 5 min at 2,400 rpm, filtered (Millex-HV,0.45µm, Lot # H2SM98164, catalog # SLHV025NB), and then stored at - 20°C.

Electrophoretic titration

Electrophoretic titration was used to measure the IpH, and surface charge of crude venom proteins. This information would be useful in selecting the proper purification protocol. A Pharmacia PhastSystem with IEF 3-9 PhastGel™ was used to run an electrophoretic titration. The separation procedure followed was obtained from the Pharmacia PhastSystem instruction manual. After the pH gradient of 3-9 was established, the gel was then rotated clockwise 90°. The venom sample (7 µg) was applied perpendicular to the pH gradient across the middle of the gel and stained with silver nitrate.

Chromatography

C. v. oreganus venom was fractionated by anion exchange chromatography using Waters high performance liquid chromatography system with Millennium 2010 software. A total protein of 8.8 mg of snake venom was injected into DEAE column and eluted with a 0.02 M Tris buffer containing 0.5 M NaCl at pH 8.0. The fractionation required 60 min with a flow rate of 1 ml/min. The absorbency was measured at 280 nm. The column was a Waters Protein Pak DEAE 5PW (7.5x7.5mm); part #: 088044; obtained from Waters Division of Millipore of the Millipore Corporation; 34 Maple Street; Milford,Ma 01757).

Hemorrhagic and minimum hemorrhagic dose assay

A modified hemorrhagic assay described by Omari-Satoh *et al.* (1972) was used to determine hemorrhagic activity. Hemorrhagic activity was determined by intracutaneous (dorsal) injection into a depilated rabbit. Before injection the fractions were diluted to a concentration of 150 µg/ml to prevent excessive hemorrhage. This insured that no more than 15 µg of *C. v. oreganus* venom was injected into the back of a rabbit. The crude venom control was tested in the same manner. The rabbit was sacrificed 24 hr later. The sample was considered hemorrhagic if the diameter of the hemorrhagic spot was 10 mm. The minimal hemorrhagic dose (MHD) was determined for crude venom and each hemorrhagic fractions. The MHD is defined as the concentration of venom which will cause a 10 mm diameter hemorrhagic spot. Hemorrhagic activity is the diameter of the hemorrhaigic spot in mm. Specific hemorrhagic activity is the diameter of the hemorrhagic spot (mm) divided by total venom protein injected (µg).

Antihemorrhagic assay

Two minimal hemorrhagic doses (MHD) of HPLC fractions were mixed with crude doubling dilutions of opossum serum and incubated at 37°C for 1 hr. One hundred microliters of each of the incubated mixtures were injected into a deplitated rabbit. The rabbit was sacrificed after 24 hr and the skin removed. The reciprocal of the highest dilution of serum blocking the minimal hemorrhagic dose was taken as the titer.

RESULTS

Electrophoretic titration of crude C.v.oreganus venom

Fig. 1 is an electrophoretic titration (ET) curve of crude *C.v.oreganus* venom run on an IEF 3-9 gel. *C.v.oreganus* venom is clearly a heterogeneous mixture of proteins with different IpH and surface charges. The surface charge of each protein can be read on the y axis and IpH can be read from the origin (x axis). The proteins had maximum surface charge distribution at pH 8 as measured by their migration toward the anode (+). Most of the proteins had an IpH less than 7 which mean that *C.v.oreganus* venom is predominately acidic.

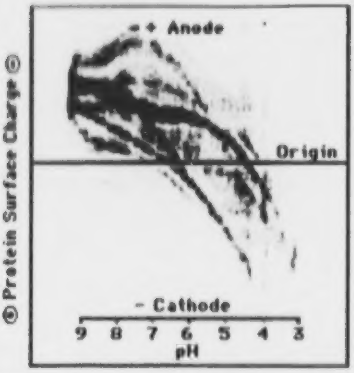

Fig.1 Electrophoretic titration for *Crotalus viridis oreganus* crude venom. A Pharmacia PhastSystem IEF 9-3 gel was used to run an electrophoretic titration. A pH of 3-9 was established. The gel was run with 3.5 µl of a 2 mg/ml *C.v. oreganus* venom sample and stained with silver nitrate.

Chromatogram Profile

C.v.oreganus venom consist of basic and acidic proteins and all hemorrhagic proteins were acidic proteins. Twelve peaks were eluted, of which peaks 5-12 were hemorrhagic. Peaks 6 and 7 were the most hemorrhagic and had a specific activity of 10 mm/µg. Proteins in peak 1 are basic proteins and proteins in peaks 3 through 12 are acidic proteins.

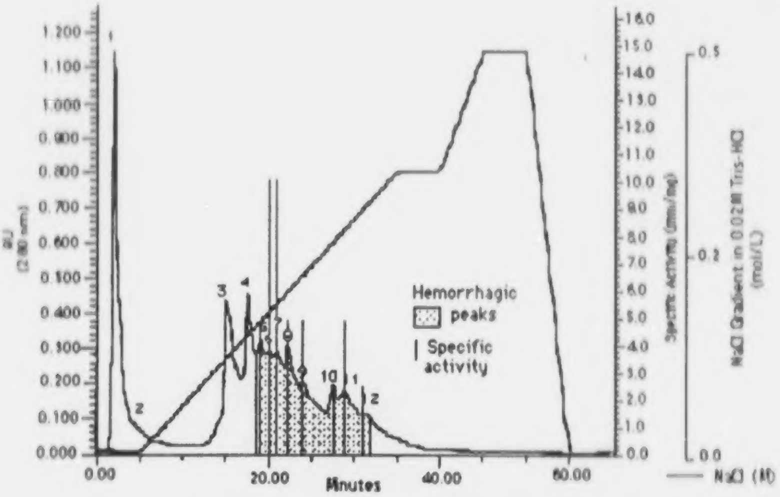

Fig. 2 Fractionation of *Crotalus viridis oreganus* crude venom using High Performance Liquid Chromatography (HPLC). *C.v.oreganus* venom fractionated by anion exchange chromatography using Waters HPLC system with Millennium 2010 software. A total protein of 8.88 mg of venom was injected into Waters protein Pak 5PW DEAE 7.5x7.5 mm column and eluted with a 0.02 M Tris-HCl buffer containing 0.5 M NaCl at pH 8.0.

Hemorrhagic, Minimum Hemorrhagic Dose and Antihemorrhagic Assay

As shown in Fig. 2, the shaded area represents hemorrhagic peaks and are in the acidic region of the venom HPLC profile. Table 1., illustrates the hemorrhagic activity for peaks 5-12. Both peaks 6 and 7 show the most hemorrhagic specific activity (10mm/µg). Peak 6 had an antihemorrhagic titer of 16, whereas, peak 7 had an antihemorrhagic titer of 8. It took the least amount of antihemorrhagic serum to neutralize peak 10 (titer of 64).

† This is the activity (mm)/ MHD or total protein injected (µg). This was also the total amount of protein injected.

¶ The reciprocal of the highest dilution of serum blocking the MHD was taken as the titer.

** There was not enough venom sample to determine antihemorrhagic titer.

DISCUSSION

C.v.oreganus venom is a complex heterogeneous mixture of both acidic and basic proteins; however, all hemorrhagic proteins were acidic. Ten percent of the proteins from *C.v.oreganus* venom are basic proteins. Of the hemorrhagic proteins (peaks 5-12), peak 6 and 7 had the highest specific activity (10 mm/µg). Metalloproteinases in the Crotalidae and Viperidae venom are the factors causing hemorrhage in the envenomated victim. Such evidence suggest that peaks 6 and 7 are metalloproteinase. The MHD for both peaks 6 and 7 is 1µg which result in a 10 mm hemorrhagic spot. Even though peaks, 6 and 7, had the same specific hemorrhagic activity, they were not neutralized at the same rate with opossum serum. A higher concentration (lower dilution) of opossum serum was required to neutralize peak 7. Peak 6 required a opossum serum dilution of 1/16 for neutralization, whereas, the neutralization of peak 7 required a 1/8 dilution. The difference in neutralization rate suggest that peak 6 and 7 are therefore different and not neutralized at the same rate. The interpretation of the data must be with caution since we were dealing with crude opossum serum and only partially purified venom. Hemorrhagic proteins from peak 10 were the least hemorrhagic and require the smallest amount of opossum serum (highest dilution 1/64) to neutralize peak 10. Further studies are required to determine if the least hemorrhagic proteins are easiest to neutralize.

Martinez *et al.* (1989) demonstrated that monoclonal antibodies can be used to detect common epitopes among different venom proteins. Monoclonal antibodies were used to screen venoms with common epitopes, thus showing an antigenic relationship between these venoms. Perez *et al* . (1989) used two different monoclonal antibodies, *C. atrox* peak 8 (CA-P-8) and *C. atrox* subclone 5 (CA-5+) produced against two *C. atrox* venom hemorrhagic fractions to show the antigenic relationship between venoms. *C.v.oreganus* was one of the seven crude venoms tested. *C.v.oreganus* proteins reacted with CA-5+, indicating that some of these proteins had similar epitopes, thus establishing an antigenic relationship between crude *C.v.oreganus* proteins and those proteins found in peak 5 of *C. atrox*.

Further studies will involve purification of*C.v.oreganus* venom toxins which are hemorrhagic and are neutralized with opossum serum. These hemorrhagins will then be used to produce monoclonal antibodies. The monoclonal antibodies could be also used in affinity chromatography for purification of hemorrhagins. In addition, monoclonal antibodies can be used to study the mechanism of neutralization of venoms. The production of a panel of monoclonal antibodies would be useful in the identification of cross reactivity of different species of snake venoms. This information would be useful to the medical practitioner in treating snakebite victims more effectively and to the herpetologists interested in evolutionary aspects of biology.

Campus Box 158
Kingsville, TX 78363

Faculty Advisor:

John C. Pérez

The Western cottonmouth (*Agkistordon piscivorus leucostoma*) is a poisonous, semi-aquatic snake which belongs to the Viperidae family and resides in the Southwestern United States. Cottonmouths are believed to be very aggressive snakes and use their venom for capturing and digesting prey. The Western cottonmouth venom is hemorrhagic. Most hemorrhagins are metalloproteinases which digest matrix proteins surrounding the endothelium of the capillaries. This causes the destruction of the endothelium and the escape of red blood cells and plasma into the surrounding tissue. The hemorrhage process is very similar to metastasis in tumors in which collagenase IV and other metalloproteinses digest proteins in the capillary matrix. Venom metalloproteinases make excellent models for studying tumor metastasis. Purification of venom metalloproteinases are essential to studying the mechanism of tumor metastasis as well as hemorrhage in snakebite victims. Electrophoretic titration was used to predict optimal conditions for separation of venom by ion exchange chromatography. The venom was fractionated by high performance liquid chromatography (HPLC) and each fraction was analyzed for hemorrhagic activity. Seven fractions were collected. Fractions 4, 5, 6, and 7 showed hemorraghic activity, and fraction 7 had the highest specific hemorrhagic activity. Their minimal hemorrhagic dose (MHD) were also determined and used to find the antihemorrhagic activity of the *Didelphis virginiana* (Virginia opossum) serum when combined with venom.

INTRODUCTION

Snake venoms are composed of many toxins which cause medical emergencies when humans are envenomated. Snakebites by rattlesnakes, cottonmouths, and copperheads usually cause immediate swelling, edema, and pain and if left untreated, will cause necrosis and possibly amputation of the affected area. Huang and Pérez (1980) reported that hemorrhage is one of the most prominent symptoms when an animal is envenomated by snakes from the Crotalidae and Viperidae families. *A. p. leucostoma* venom is hemorrhagic and hemotoxic. Hemorrhagic toxins (metalloproteinases) disrupt the basement membrane and cause lysis of endothelial cells (McKay *et al.*, 1970). Mortality rate in the United States, due to envenomation of *A. p. leucostoma* is not significant, but permanent tissue damage may occur through edema, hemorrhage and necrosis. Metalloproteinases not only cause the escape of red blood cells (hemorrhage) but also cause the escape of tumors cells from the capillaries which is known as metastasis. Purification of venom metalloproteinases are important in the study of hemorrhage and tumor metastasis. Tumors have metalloproteinases in low concentration and are difficult to purify. There are many structural and sequence homologies between venom and mammalian metalloproteinases. These similiarities make snake hemorrhagins excellent models for designing metalloproteinase inhibitors (Botos, *et al.*, 1996).

The extracellular matrix digestion with matrix metalloproteinases is a critical component of many physiological and pathological conditions. The physiological and pathological processes may only differ by the way in which extracellular matrix digestion is regulated. While the physiological roles of mammalian metalloproteinases are to digest extracellular matrix in a controlled manner during tissue remodeling, differentiation, and wound healing, many pathological conditions are caused by uncontrolled matrix degradation. Uncontrolled matrix degradation results in excessive tissue destruction, disruption of matrix boundaries and loss of matrix function. Examples of pathological metalloproteinase expressions are envenomation from snakebites and invasiveness by a variety of human tumors (breast, colon, thyroid, hepatocellular, lung and prostate cancers).

All proteinases in circulation are subject to the influence and regulation by plasma proteinase inhibitors. Intrinsic enzymes, such as clotting factors, and extrinsic enzymes, such as hemorrhagic toxins have little activity if they are neutralized by inhibitors (Travis and Solvesen, 1983). The α-2-macroglobulin is a major metalloproteinase inhibitor (Starkey and Barrett, 1977, Werb *et al.*, 1974). Bjernson and Tu (1978) reported five hemorrhagic toxins (HT-a, HT-b, HT-c, HT-d, and HT-e) in *Crotalus atrox* venom. The proteolytic activities of

BEST COPY AVAILABLE

hemorrhagic toxins HT-c and HT-c/d toward the large molecular weight gelatin type I and collagen IV were completely inhibited by α-2-macroglobulin. The activity of HT-a on the same protein substrate was not significantly inhibited. This is interesting since HT-a is the most hemorrhagic protein.

Studies have been done in which several animal sera were shown to neutralize the effects of snake metalloproteinases (Kilmon 1976; Werner and Vick 1977; and Pérez *et al.*, 1978). *D. virginiana*, (Virginia opossum) was first reported by Kilmon (1976) and then by Werner and Vick (1977) to have a remarkable, natural resistance to snake venom. Pérez *et al.* (1978) reported *Neotoma micropus* (gray woodrats) to be resistant to the hemorrhagic activity of the Diamondback rattlesnake (*C. atrox*) venom. The purpose of this study was to purify and characterize the *A. p. leucostoma* venom and to determine the neutralization characteristics of the Virginia opossum serum on *A. p. leucostoma* venom.

MATERIALS AND METHODS

Venom/snake

A. p. leucostoma was originally collected from Lafayette, Lousiana and is presently housed in Texas A&M University Kingsville Serpentarium. The snake currently weighs 611 g and is 88 cm in length. The venom was collected, centrifuged using a Beckman Avanti™ 30 Centrifuge at 3,500 rpm for 5 min, and filtered using a Millipore MillexHV 0.45μm filter unit. The venom was stored at -90°C.

Sera

The opossums were obtained from the Animal Control Center of Kleberg County, TX. Sera was collected from *D. virginiana* by heart puncture. The blood was stored at -4°C for 24 hr and then centrifuged using a Beckman Avanti™ 30 Centrifuge at 3,500 rpm for 10 min. After centrifugation the opossum serum was collected and stored at -90° C until used.

Electrophoretic titration

Electrophoretic titration of the crude venom was conducted to determine the optimal conditions for separation of venom by ion exchange chromatography. The pH gradient (3-9) was established using a Pharmacia PhastSystem with an IEF 3-9 gel. *A. p. leucostoma* venom (7 μg) was applied to the gels and rotated 90°. Electrophoresis was conducted as outlined in the Pharmacia manual and the gel was stained with silver nitrate.

Anion exchange chromatography

A. p. leucostoma venom was fractionated using a method described by Soto *et al.* (1989). Two-hundred-and-fifty microliters of venom, 38.8 mg/ml were injected into a Waters HPLC System using a Waters Protein-Pak™ 5PW-DEAE column (7.5 x 75 mm). The elution buffers used to establish a salt gradient were 0.02 M Tris-HCl, pH 8, and 0.02M Tris-HCl, pH 8 containing 0.5 M NaCl. The absorbance of the venom fractions collected was monitored at 280 nm using a Waters 484 tunable absorbance detector. Each fraction was collected and the absorbance was taken using an LKB Biochrom Ultraspec II at 280 nm. All the fractions were stored at -20°C.

Hemorrhagic assay and minimal hemorrhagic dose

Crude *A. p. leucostoma* venom and fractions collected were tested for hemorrhagic activity. A modified method of Omori-Satoh *et al.* (1972) was used to measure hemorrhagic activity. New Zealand rabbits were injected intracutaneously with 0.1 ml of 150 μg/ml of each venom fraction collected. The rabbit was sacrificed 24 hr later, and the diameter of the hemorrhagic spots (hemorrhagic activity) were measured. The minimum hemorrhagic dose (MHD) was determined for crude venom and each fraction. MHD is defined as the minimum amount of venom which causes a 10 mm hemorrhagic spot. The specific activity was determined by dividing the hemorrhagic activity by the amount of total protein (mg) injected.

Antihemorrhagic assay

The method described by Huang and Pérez (1980) was used to determine the antihemorrhagic activity of *D. virginiana* sera. The MHD for each fraction were combined with equal amounts of various serial dilutions of sera and incubated for 1 hr at 25°C. A volume of 0.1 ml for each solution was injected intracutaneously into the back of depilated rabbits. The rabbits were sacrificed after 24 hr and the diameter of the hemorrhagic area was measured.

RESULTS

Electrophoretic titration of crude *A. p. leucostoma* venom

Figure 1 is an electrophoretic titration (ET) curve that was obtained using crude *A. p. leucostoma* venom. The proteins in the ET curve were mainly acidic since most of the IpH were below 7. Multiple bands in Figure 1 indicate that *A. p. leucostoma* venom is a heterogenous mixture of proteins. The maximum surface charge distribution for venom proteins was in the range of 7 through 8.5. The titration curve also indicated that most of the proteins could be optimally separated by HPLC using an eluding buffer above pH 7 and anion exchange (+) column since most proteins had a maximum surface charge distribution at this pH.

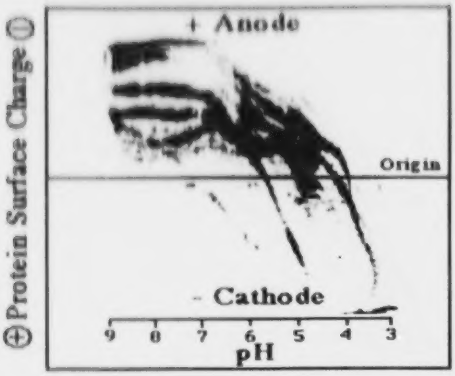

Figure 1. Electrophoretic titration for crude *A. p. leucostoma* venom. A Pharmacia Phast System with LKB IEF 3-9 gel was used for titration. A pH gradient of 3-9 was established. Three-and-one-half microliters of *A. p. leucostoma* venom sample (2 mg/ml) were injected in the system and then developed by silver nitrate staining. Optimal separation of proteins in HPLC were obtained using a buffer pH 8.

HPLC chromatogram

A. p. leucostoma venom was fractionated using the Waters HPLC System. Figure 2 illustrates that there were a total of seven peaks collected. The proteins in the first peak were in the basic region of the HPLC chromatogram while the proteins in fractions 2-7 were in the acidic region. The most acidic protein would have greatest affinity for the DEAE matrix (+) and would be eluted last. The basic proteins in peak 1 had a positive charge and were eluted with the void volume. None of the proteins in peak 1 were hemorrhagic. The acidic proteins in peaks 4-6 were hemorrhagic. The hemorraghic activity and specific hemorrhagic activity of every hemorrhagic peak collected from HPLC fractionation is tabulated in Table 1 and shown in Figure 2. The most hemorrhagic fraction was peak 6 with an MHD of 2 µg. The fraction with the highest specific activity was peak 6 with a specific activity of 5 mm/µg. Both peaks 4 and 5 had the lowest specific hemorrhagic activity which was 1 mm/µg.

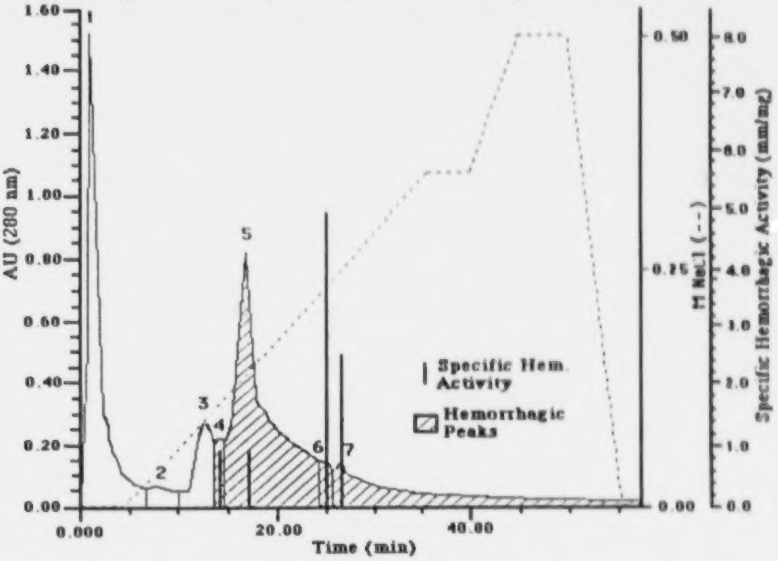

Figure 2. Fractionation of *A. p. leucostoma* crude venom using high performance liquid chromatography (HPLC). Two-hundred and fifty microliters of crude *A. p. leucostoma* venom (38.8 mg/ml) in 0.02 M Tris-HCl, pH 8 buffer were injected into a Waters HPLC System containing a Waters Protein-Pak 5PW-DEAE (7.5 x 75mm) column. The absorbance was detected at 280 nm.

Sera antihemorrhagic titer

The opossum serum antihemorrhagic titers are tabulated in Table 1. The titer is the reciprocal of the highest dilution of *D. virginiana* sera which neutralizes an MHD. Peaks 5 and 6 had the highest antihemorrhagic titer of 256. Antihemorrhagic titer of 128 was obtained for peak 4. It required more opossum sera to neutalize peak 4 than it took to neutralize peaks 5 and 6. Titers for peaks 1-3 were not obtained since they were not hemorrhagic.

TABLE 1. Hemorrhagic assay on each fraction collected of *A. p. leucostoma* venom and the capacity of *D. virginiana* sera to neutrilize *A. p. leucostoma* venom.

DISCUSSION

The results demonstrate that electrophoretic titration is an excellent technique to determine the optimal conditions for protein separation by ion exchange chromatography. The titration curve provided useful information about the characteristics of *A. p. leucostoma* venom. The multiple bands indicated that crude *A. p. leucostoma* venom is a complex mixture of proteins. The venom proteins in the ET curve had the greatest surface charge distribution in a pH range of 7 to 8. A buffer with a pH of 8 and DEAE (+) column would be an excellent matrix for separation of crude *A. p. leucostoma* venom. The ET curve and the HPLC chromatogram clearly indicate that the venom was composed of both acidic and basic proteins. Both figures show *A. p. leucostoma* venom has more acidic than basic proteins. The IpH of the proteins can be measured from the titration curve at the points where the surface charge on the proteins is zero. Proteins with an IpH of 7 or less are acidic proteins.

The chromatogram obtained from HPLC fractionation shows seven peaks of which four were hemorrhagic. Proteins in Peak 1 at pH 8 have positive charges and are basic. These non-hemorrhagic proteins eluted with the void volume. Peak 1 proteins along with proteins in peaks 2 and 3 were not hemorrhagic. Proteins in peaks 4-7 were acidic and showed hemorrhagic activity. All the hemorrhagic fractions were acidic proteins which was consistant with the findings of Bjarnason and Tu (1978). All but one hemorrhagic protein (Ht-b) isolated from *C. atrox* venom were acidic (Bjarnason and Tu, 1978). Hemorrhagic proteins are metalloproteinases which disrupt the basement membrane and cause escape of red blood cells into the surrounding tissue.

The venom fractions collected, which had a measureable hemorrhagic activity, were neutralized with serial dilutions of *D. virginiana* sera. Pérez *et al.* (1978) reported that a number of warm-blooded animals have antihemorrhagic factors which allow for greater survival when bitten by a poisonous snake. The results from this study and other studies made by Kilmon (1976), Werner and Vick (1977), and Pérez *et al.*, (1979) strongly indicate that *D. virginiana* has a remarkable antihemorrhagic resistance to various venomous snakes. The neutralization capacity of *D. virginiana* serum on peaks from crude *A. p. leucostoma* venom was determined. Fractions 5 and 6 had the highest antihemorrhagic titer of 256 which means these fractions were easily neutralized. The hemorrhagic activity of peak 6 was higher than peak 5 but neutralized with opossum serum at the same rate. More opossum serum (a titer of 128) was required to neutralize peak 4 even though it had the same hemorrhagic activity as peak 5. It is important to notice that the most hemorrhagic fractions required less opossum serum for neutralization.

McKay *et al.*, (1970) reported that hemorrhagic toxins in snake venoms are metalloproteinases which break the basement membrane in cells and cause the lysis of

BEST COPY AVAILABLE

endothelia cells. These hemorrhagic metalloproteinases have high degree of similarity with metalloproteinases that are found in tumor cells which make them excellent models for studying cancer (Botos, *et al.* 1996). The metalloproteinases found in tumor cells interact with the basement membrane causing proteolysis which initiates the metastatic cascade (Stetler-Stevenson *et al.*, 1993). Hemorrhagic toxins (metalloproteinases) in venom are very abundant and makes venom an excellent source of metalloproteinases. Metalloproteinases in venom and in tumors of mammals work in a very similar way. Antihemorrhagic factors in the opossum serum neutralize the venom metalloproteinases and prevent hemorrhage. These same antihemorrhagins could also prevent metastasis of tumors. Thus, it is of extreme importance to purify the metalloproteinases in venom and antihemorrhagins in opossum serum to determine the mechanism of neutralization. Once this mechanism is understood then the metastasis cascade could also be inhibited. Thus, the next step of this study is to continue the purification of hemorrhagic fraction until pure metalloproteinases can be obtained to determine the structure of the protein.

Crotalus viridis lutosus (Great Basin rattlesnake) is a member of the Viperidae family. The *C. v. lutosus* venom is classified as a hemorrhagic venom. The purpose of this study is to investigate the hemorrhagic ability of *C. v. lutosus* venom. An electrophoretic titration curve was used to determine optimal conditions for high performance liquid chromatography (HPLC). A total of 11 peaks were collected from DEAE fractionation, and each fraction was tested for hemorrhagic activity. Peaks 4-11 were hemorrhagic and the specific hemorrhagic activity of each were determined. Peaks 6 and 7 resulted in the highest specific hemorrhagic activities which were both 6.67 mm/μg. All hemorrhagic fractions and crude venom were neutralized by crude *Didelphis virginiana* (Virginiana opossum) serum. The long range goal of this research is to purify snake hemorrhagins which are neutralized by opossum serum and sera from animals with a natural resistance to snake venom.

INTRODUCTION

Crotalus viridis lutosus (Great Basin rattlesnake) is a member of the pit viper group and subfamily Crotalidae. The Great Basin rattlesnake is one of nine recognized subspecies of western rattlesnakes (Klauber, 1956). Mainly dominating in the west, it ranges from the Rockies to Sierras, including southeastern Oregon, northern California, southern Idaho, central Nevada, and western Utah . The hemorrhage produced by these rattlesnakes is one major symptom in bite-manifestation of Crotalid and Viperid snakes (Masahiko *et al.*, 1995). Human envenomation by *C. v. lutosus* may include clinical signs of edema, eccymosis, hemorrhage, defibrination, hypotension, local necrosis and, very rarely, death. Soto *et al.* (1989) reported that the antihemorrhagic activity in sera from resistant animals neutralizes hemorrhagins from different snake venoms. The venom of this subspecies contains several enzymatic activities relatively common to rattlesnake venoms, i.e. L-amino acid dehydrogenase, hide powder azure protease, phosphodiesterase, and phospholipase activities (Aird *et al.*, 1988).

Adame *et al.* (1990) reported latitudinal distribution of specific hemorrhagic activity and enzyme linked immunoadsorbent (ELISA) activity using monoclonal antibody (CA-P-8). In this study CA-P-8 monoclonal antibody was used to screen *C. v. lutosus* from different localities. The antibody recognized the most hemorrhagic fraction in pooled venom from the northeast and northcentral Utah but failed to react against venom from southern Utah.

As harmful as venom may be to humans, there are a few animals that display an unusual resistance to snake venoms. Perez *et al.* (1978a) reported that gray woodrats (*Neotoma micropus*) were able to endure 121 times more *Crotalus atrox* venom than Balb/c mice. The Virginiana opossum (*D.virginiana*), Mexican ground squirrel (*Spermophilus mexicanus*), hispid cotton rat (*Sigmodon hispidus*), and the gray woodrat (*Neotoma micropus*) all have a natural resistance to snake envenomation (Kilmon, 1976; Perez *et al.*, 1978b). The resistance of certain mammals to hemorrhagic venoms appears to be due to the presence of antihemorrhagic factors in the sera (Perez *et al.*, 1978b; Pichyangkul and Perez, 1980; Menchaca and Perez, 1981; and Garcia and Perez, 1984).

The goal of this study was to purify hemorrhagic toxins in *C. v. lutosus* venom and determine which fractions react with crude opposum serum.

MATERIALS AND METHODS

Venom collection

C. v. lutosus venom was obtained from the VA Hospital in Salt Lake City, Utah. The venom was centrifuged and filtered using a Millipore Millex® HV 0.45 µm filter unit. The venom was stored at -90°C.

Serum collection and preparation

The serum from *D. virginiana* was collected by heart puncture. The serum was centrifuged at 3,500 rpm for 10 min at 4°C on a Beckman Avanti™ 30 Centrifuge and stored at -90°C.

Electrophoretic titration curve

A volume of 3.5 µl of a 2 mg/ml *C. v. lutosus* venom sample was separated by electrophoretic titration using a Pharmacia Biotech PhastSystem. A pH gradient of 3-9 was established on a polyacrylamide IEF 3-9 PhastGel. The gel was rotated 90° and venom sample applied. The gel was then stained with silver nitrate. The same electrophoretic titration procedure was followed for other hemorrhagic factors that would be further purified.

Fractionation by High Performance Liquid Chromatography (HPLC)

Two hundred and fifty microliters of crude *C. v. lutosus* venom (41.2 mg/ml) was injected into a Waters Protein-Pak DEAE 5PW (7.5 x 75 mm) HPLC column. Fractions were eluted using a 0.02 M Tris-HCl buffer, pH 8.0, and 0.5 M NaCl over a period of 60 min with a flow rate of 1 ml/min. A Waters 484 tunable absorbance detector was used to detect the absorbance at 280 nm of the fractions. Millennium software v.2.15 on a Digital Venturis 466 computer was used to control the pumps and store the data obtained. Fractions were stored at -20°C.

Hemorrhagic assay

A hemorrhagic assay was performed to determine the minimal hemorrhagic dose for crude *C. v. lutosus* venom and for the fractions collected (Omori-Satoh *et al.*, 1972). Fractions were diluted to concentrations of no more than 150 µg/ml, of which 0.1 ml was injected subcutaneously onto the back of a depilated New Zealand rabbit to test for activity. After 24 hr, the rabbit was sacrificed. The hemorrhagic spots were measured and the specific activity calculated for each fraction. The MHD is defined as that concentration of venom which causes a 10 mm hemorrhagic diameter. The specific hemorrhagic activity was determined by dividing the hemorrhagic activity (mm) by the total protein injected.

Antihemorrhagic assay

Equal amounts of the MHD of crude and fractionated venom were mixed with serial dilutions of opossum serum (*D. virginiana*) and incubated for 1 hr at 23°C. The back of a New Zealand rabbit was depilated and 0.1 ml was injected. The rabbit was sacrificed after 24 hr. The antihemorrhagic activity was taken as the reciprocal of the highest dilution of serum which neutralized the MHD.

RESULTS

The electrophoretic titration curve (figure 1) indicates that *C. v. lutosus* venom is acidic and the IpH and protein surface charges can be measured. The IpH range was 3-6 and can be observed on the x axis at the origin. Differences in the surface charge are view on the y axis.

Figure 2 shows the hemorrhagic fractions as well as the specific activity of each fraction. Eleven fractions were collected by anion exchange chromatography and eight of these were hemorrhagic. All hemorrhagic fractions were acidic proteins. Proteins in fraction one have a positive charge and eluted with the void volume on a DEAE column. These proteins are basic and were not hemorrhagic, as opposed to the other 10 that have negative charges. From this chromatogram, it can be concluded that *C. v. lutosus* venom is complex mixture of mainly acidic proteins.

Table 1 lists the hemorrhagic activity and specific activity for each of the fractions collected by HPLC. As seen on this table, fractions 4-11 were determined to be hemorrhagic. Fractions 6 and 7 had the highest specific activity of 6.67 mm/µg and the lowest MHD, 1.5 µg.

Serum from the *D. virginiana* was tested for its neutralizing ability on the crude *C. v. lutosus* venom, as well as the hemorrhagic fractions. *D. virginiana* sera neutralized all hemorrhagic fractions and crude *C. v. lutosus* venom. Crude venom is neutralized by a titer of 128 while the fractions with the highest hemorrhagic specific activity (fractions 6 and 7) are neutralized by a titer of 4 and 16, respectively.

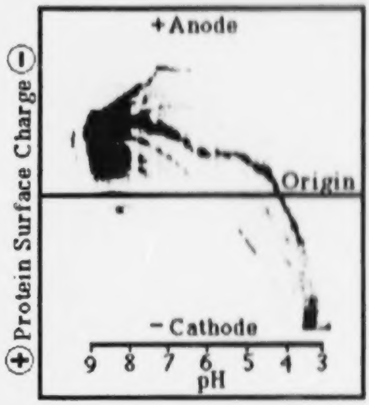

Figure 1. Electrophoretic titration curve for crude *C. v. lutosus* venom. Three and one half microliters of a 2 mg/ml venom sample was applied to a Pharmacia Biotech PhastSystem on a polyacrylamide IEF 3-9 PhastGel. The gel was stained with silver nitrate. From the electrophoretic titration curve, it can be seen that the pH range for the buffer is approximately in the range of 6-8 and a DEAE column should be used. The intensity of the protein surface charge at various pH can be seen.

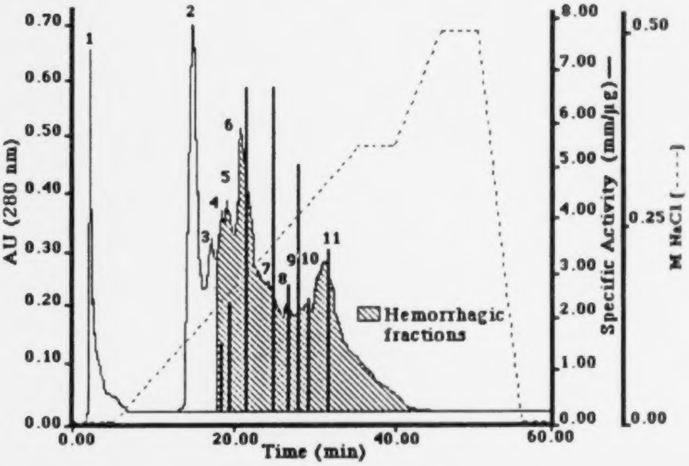

Figure 2. Determination of hemorrhagic and specific hemorrhagic activity for the fractions collected for *C. v. lutosus*. The venom sample was fractionated by anion exchange chromatography. Two hundred and fifty microliters of venom (41.2 mg/ml) was injected into a Waters Protein-Pak DEAE 5PW (7.5 x 75 mm) HPLC column. The fractions were eluted with 0.02 M Tris-HCl, pH 8.0 and 0.5 M NaCl gradient was used. The collection required 60 min with a flow rate of 1 ml/min and an absorbance of 280 nm. A total of 11 fractions were collected. A hemorrhagic assay was performed on the fractions collected by the Waters HPLC System through an anion exchange column. Peaks 4-11 were determined to be hemorrhagic as indicated by shaded area. The specific hemorrhagic activity of each was determined by dividing the hemorrhagic activity by the total protein injected, represented by solid line.

TABLE 1. SPECIFIC HEMORRHAGIC ACTIVITY, MINIMAL HEMORRHAGIC DOSES, AND ANTIHEMORRHAGIC TITER FOR *C. V. LUTOSUS* VENOM

Venom Sample §	Specific Activity (mm/µg) *	MHD (µg) £	TITER ¥
Crude	0.48	2.1	128
Fractions 1-3 •	0	0	0

Fraction 10	2.50	4.0	8
Fraction 11	3.22	3.1	Δ

§ The venom samples correspond to the crude *C. v. lutosus* venom, as well as the hemorrhagic fractions (Figure 2).

* Specific activity was calculated by dividing the 10 mm spot produced by the total protein injected.

£ The MHD is the total protein required to produced a 10 mm spot.

¥ The antihemorrhagic titer is defined as the reciprocal of the highest dilution of animal sera that neutralizes a MHD.

• Fractions 1-3 were not hemorrhagic.

Δ Not enough sample to determine the antihemorrhagic titer.

DISCUSSION

Electrophoretic titration was the method used for determining optimal conditions for separation by ion exchange chromatography. Not only does this method predict the pH range and column to be used, but it allows us to see if the proteins are acidic or basic, whether the proteins are heterogeneous, the intensity of the surface charge of proteins at the various pH, and the isoelectric point of the different proteins can also be predicted. Some of the same conclusions can be reached by separation of the protein by ion exchange chromatography but would require repeated runs to obtain optimal separation. Basic and acidic proteins were observed in Fig. 2. Protein in peak 1 were eluted with the void volume since they are basic proteins and have a positive charge at pH 8 and do not bind to DEAE matrix. Peaks 2 through 11 were eluted with various salt concentrations. Peak 2 has weak negative charge and elutes first, and peak 11 is the most negative charged protein and has the greatest affinity for the matrix. In the study, it was concluded that *C. v. lutosus* venom is heterogenous and mainly acidic (figures 1 and 2). These findings confirm the work of Adame *et al.* (1990) in which venom from three different geographical regions were fractionated by HPLC/DEAE chromatography. The specific hemorrhagic activity of the snakes in northern Utah was greater than specific activity in Southern Utah.

Eight out of 11 fractions collected by HPLC were hemorrhagic (figure 2). The specific activities of each of the hemorrhagic fractions were determined (table 1). Fractions 6 and 7 have the highest specific activities, 6.67 mm/µg, and have the same MHD, 1.5 µg. Each hemorrhagic peak (MHD) were neutralized by crude *D. virginiana* serum with varying titers (table 1). Although fractions 6 and 7 have the same specific activities and MHD, the antihemorrhagic titers used to neutralize the venom were different. Fraction 6 was neutralized by a titer of 4, while fraction 7 by a titer of 16. The results of this substantiate the findings of numerous investigators who reported that opossum neutralizes all hemorrhagic venoms and venom fractions (Kilmon 1976, Perez *et al.*, 1978a & b, Soto *et al.*, 1989, Menchaca and Perez 1981, and Pichyangkul and Perez 1980).

C. v. lutosus hemorrhagic fractions purified in this study will be used to construct an affinity column to purify antihemorrhagins in opossum serum. Once purified hemorrhagins and antihemorrhagins are obtain the mechanism of venom neutralization will be studied in resistant animals. Understanding the mechanisms in which antihemorrhagins neutralize snake venom, could be used in snakebite treatment.

The Western Diamondback rattlesnake, *Crotalus atrox*, is found in the southwestern portion of the United States. It is the second largest rattlesnake in North America and is extremely aggressive. Venom from *C. atrox* is one of the most studied venoms. The venom has been reported to contain seven hemorrhagins which consist mainly of metalloproteinases. These metalloproteinases are responsible for the degradation of the endothelium cells in capillaries which allows blood to escape into surrounding tissue. Metalloproteinases that have been isolated from *C. atrox* venom can be used to explore the binding specificity of anti-tumor drugs. This study used electrophoretic titration to predict the best protocol for high performance liquid chromatography (HPLC) on crude *C. atrox* venom. Preliminary results indicate that individual venom samples are different and may contain less than seven hemorrhagins as originally reported for pooled *C. atrox* venom. If the venom composition is different the symptoms of venom envenomation may differ. Results of electrophoretic titration indicated that the best pH for separating *C. atrox* venom was a pH of 8.0 with a DEAE-anion exchange column. Twenty-one peaks were obtained and fourteen were hemorrhagic, with peak 8 having the highest specific hemorrhagic activity. The isolation of these hemorrhagins are essential for developing better treatment and in developing metalloproteinase inhibitors.

INTRODUCTION

The Western Diamondback rattlesnake, *Crotalus atrox*, is native to the southwestern United States and Mexico. Venoms from the Crotalidae family of snakes are among the most hemorrhagic. Snake venom is used for the capture and initial digestion of prey. Venom is composed of a mixture of proteins, many of which are toxic. Metalloproteinases in venom cause destruction of endothelium cells in capillary beds allowing blood to be discharged into surrounding tissue. The current medical treatment for snakebites involves the administration of antivenin which has often resulted in causes complicating anaphylactic symptoms in the victim. Bajarnson and Tu (1978) reported that *C. atrox*, Western Diamondback rattlesnake, has five hemorrhagins in pooled venom. Even though venom is hemorrhagic, it has been discovered that several warm-blooded animals possess a natural resistance to venom of snakes from the Crotalidae family (Perez *et al.*, 1979, 1992). To understand the mechanism of resistance, one must first understand the toxic properties of venom. A fundamental requirement in studying venom is purification.

Electrophoretic titration (ET) is a powerful tool that can be used to predict the appropriate pH and type of column for further separation of venom by high performance liquid chromatography (HPLC). In electrophoretic titration a uniform polyacrylamide gel provides a porous network through which the venom will migrate in an electric field at different pH. Proteins are amphoteric molecules whose charge can be manipulated by changes in pH. At the isoelectric point, the proteins will carry a net neutral charge and will not migrate. At a pH less than the IpH, the protein will carry a positive charge and will migrate toward the cathode. Proteins subjected to a pH greater than their IpH will carry a negative charge and will migrate to the anode. The migration of proteins in a pH gradient (electrophoretic titration) can be used to predict the optimal conditions for purification of venom by HPLC. In ion exchange chromatography, a complex mixture of proteins, such as venom, can be separated on the basis of charge. A pH should be selected in which the proteins have a maximum difference in surface charge. Electrophoretic titration is an excellent tool for selecting the proper pH for ion exchange chromatography.

MATERIALS AND METHODS

Venom

Venom for this study was obtained from a pooled venom sample of snakes held at the Texas A&M University-Kingsville Serpetarium. The typical yield of venom for a captive Western Diamondback rattlesnake is 1.0 mL of venom per snake. The average size of a Western Diamondback rattlesnake at the TAMUK Serpetarium is 1.5 m. All venom collected was frozen at -90°C after receipt.

Electrophoretic titration curve

One milligram of crude *Crotalus atrox* was dissolved into 1 mL of deionized water. The solution was then centrifuged for 5 min at 7000 rpm (IEC Clinical Centrifuge). The supernatant was filtered through a 0.45μm micron versapor filter. Electrophoretic titration was implemented on a Pharmacia Biotech Phast System. A pH gradient (3.0-9.0) was established using an IEF 3-9 polyacrylamide gel (Pharmacia Biotech). The gels were rotated 90° clockwise and then the venom sample was applied to the gel. Electrophoretic titration curves were performed for crude *C. atrox* venom and the for the collected fractions from further purification procedures. The total protein applied for crude venom was 0.01 mg. The total protein applied to the IEF gel for peak 8 (Fig. 2) was 0.00418 mg and for fraction 11 (Fig. 5) the total protein applied to the gel was 0.00003 mg. The proteins were allowed to migrate for 20 min at 200V. The gel was then stained with a 0.4% silver nitrate solution using the Pharmacia Biotech Developer. All separation and developing techniques were implemented as outlined in the Pharmacia Biotech Manual Phast Gel Silver Kit 11-B-080-09.

High performance liquid chromatography (HPLC)

A *C. atrox* venom sample was fractionated by anion exchange high performance liquid chromatography (HPLC). The total protein injected into the HPLC system was 15 mg. The two buffers used were 0.02 M Tris-HCl, pH 8.0, and 0.02 M Tris-HCl containing 0.5M NaCl, pH 8.0. The column chosen for separation based on results from electrophoretic titration was a Protein Pak DEAE 5PW (7.5X75mm) HPLC column manufactured by Water Division of Millipore Corporation. The total run time was 60 min. The fractions with a low absorbancies were lypholized to concentrate the protein.

Hemorrhagic activity

A modified method of Omori-Satoh *et al.* (1972) was used. The fractions were diluted to a concentration of 0.15 mg/mL and 0.1 mL was injected by a subcutaneous (dorsal) injection administered on New Zealand adult rabbits. The controls were: 0.02 M Tris-HCl buffer A ,pH 8.0, 0.02 M Tris-HCl buffer B, pH 8.0, (0.5 M NaCl), 2.5 μg crude *C. atrox* venom (1 MHD). An MHD is the amount of protein injected that will produce a 10 mm hemorrhagic spot. The mice were sacrificed after 24 hr and hemorrhagic spots were measured. Specific hemorrhagic activity was determined by dividing the diameter of the hemorrhagic spot by the total protein concentration of venom injected.

RESULTS

Several bands were visible on the IEF gel for crude *C. atrox* venom. Each band indicated that the venom is composed of proteins which have different mobilities at varying pH (Fig 1). The best separation is evident at a pH range between 7.0 and 8.0. Between pH 7 and 8, the majority of proteins contain a negative charge and have migrated toward the anode. The maximum surface charge distribution was observed at a pH of 8.0 which indicated that an anion exchange column (DEAE) at a pH of 8.0 would provide optimal separation.

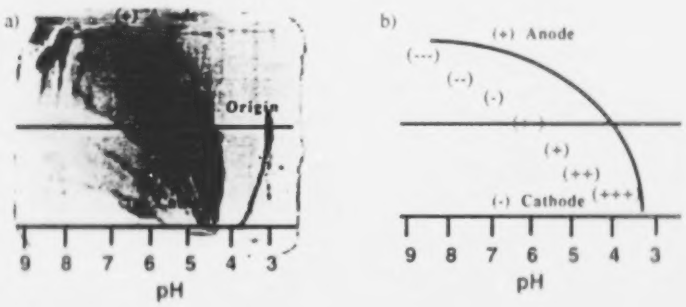

Figure 1. a) Electrophoretic titration curve of *C. atrox* venom using an IEF 3-9 polyacrylamide gel (Pharmacia BioTech). A total of 0.01 mg of protein was applied to the gel, and placed into the Pharmacia Phast System for separation and development. b) Model of surface to charge ratio of proteins as they are altered by changes in pH. As the pH is decreased, the surface charge becomes more positive and migration proceeds toward the cathode.

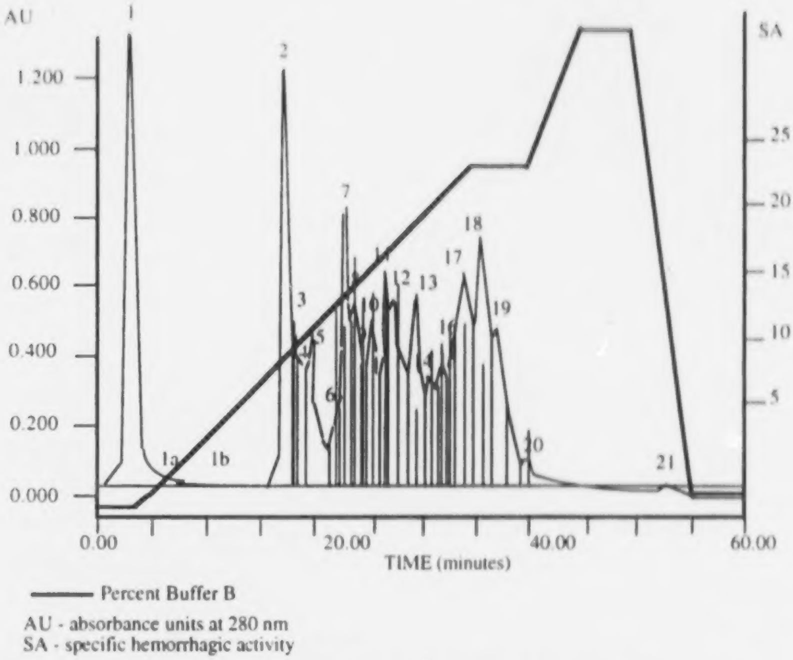

Figure 2. Anion exchange high performance liquid chromatography profile on crude *Crotalus atrox* venom. The total protein injected into a 0.02 M Tris-HCl buffer, pH 8.0 was 15 mg. A 0.5 M NaCl gradient was utilized to elute those proteins with a greater affinity for the stationary phase. The column used for separation was a Protein Pak DEAE 5PW (7.5X75mm) HPLC column manufactured by Waters Division of Millipore Corporation with a run time of 60 min. Specific hemorrhagic activity is denoted by the vertical lines.

The twenty-one fractions were collected and specific hemorrhagic activity was then measured. Of the twenty-one peaks, peaks 3, and 6-19 were hemorrhagic. The peak with the highest specific hemorrhagic activity is peak 8 which produced a 2.25 cm hemorrhagic spot. An evident distinction between the two titration curves is the shifting of peak 8's curve to the right. This shift is a result of differences in the isoelectric pH ranges of the proteins contained in peak 8. Peak 8 (Fig. 2) was more acidic; therefore, it is composed of proteins that could be better separated at a lower pH. From the electrophortic titration curve, the optimal range for further purification of peak 8 was a pH range between 6.0 and 7.5. At a pH of 7.3 it would appear that the fraction would contain few positively charged proteins as the gel had few bands that migrated toward the anode (Fig. 4). The electrophoretic titration curve indicated that the components of peak 8 were highly acidic. Acidic proteins containing negative charges could be further purified by using an anion exchange column.

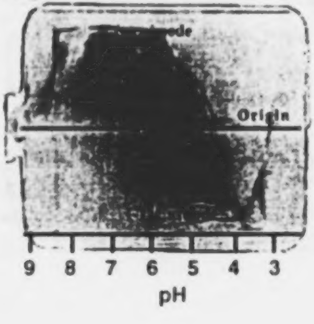

Figure 4. Electrophoretic titration curve of peak 8 using an IEF 3-9 Polyacrylamide gel (Pharmacia BioTech). Peak 8 was the fraction with the highest specific activity and the most hemorrhagic fraction. The total protein applied to the IEF 3-9 gel was 0.00418 mg. The gel was then placed into the Pharmacia Phast System for separation and development (Phast Silver Kit Instruction Manual 11-B-080-09).

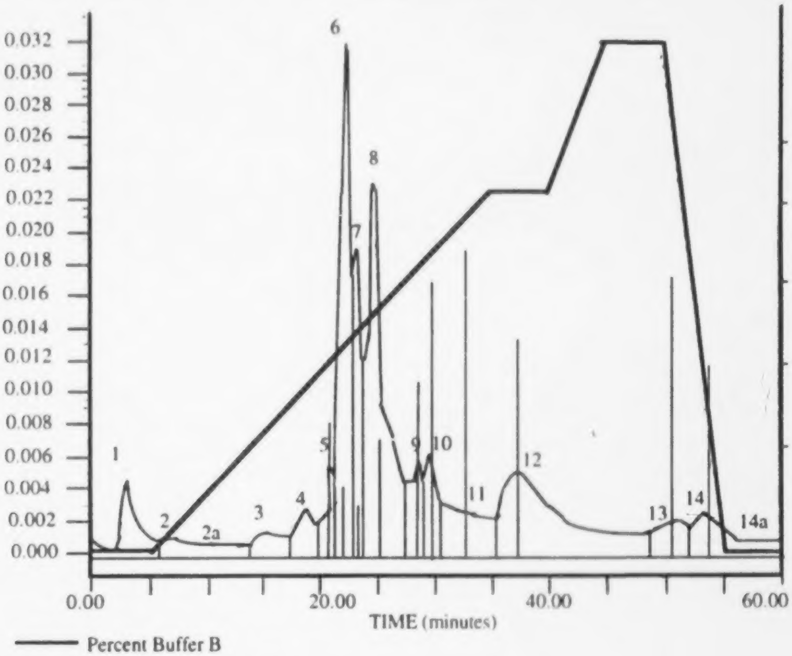
Peak 8 was further fractionated at a pH of 7.3 utilizing a 0.02 M Tris-HCl buffer. The HPLC profile for this separation provided 14 fractions (Fig 5.) Of the 14 fractions, 10 were hemorrhagic. The venom fraction with the greatest specific activity was number 11. The fraction with the greatest specific activity was not a peak, but was a valley, that was collected separately during the initial fractionation. The concentration of fraction 11 was quite low and via spectrophotometric measurements it equaled only 0.006 mg/mL. Due to the low concentration the venom was lypholized prior to evaluation by electrophoretic titration.



AU - absorbance units at 280 nm
SA - specific hemorrhagic activity

Figure 5. High performance liquid chromatography profile on peak 8. The total protein injected into the HPLC system was 0.100 mg. The elution buffers included a 0.02 M Tris-HCl buffer, pH 7.3, and a 0.02 M Tris-HCl buffer with 0.5 M NaCl as a gradient used to aid in elution of the proteins containing a greater surface charge ratio. The column used for separation was a Protein Pak DEAE 5PW (7.5X75mm) HPLC column manufactured by Waters Division of Millipore Corporation. Hemorrhagic activity is denoted by the vertical lines. The peak with the highest specific hemorrhagic activity is not a peak but the valley collected as fraction 11.

By lypholization, the components of fraction 11 became more concentrated. The fraction was then reconstituted in 100μL of deionized water. Electrophoretic titration was then performed on fraction 11 (Fig.6) and provided a protocol for the further purification of this fraction. The electrophoretic titration of fraction 11 showed one distinct band. Again as expected the IpH of the proteins in this fraction have shifted to the right, indicating that the proteins in this fraction are more acidic. This results was expected because of the position of the fraction 11 on the HPLC profile (Fig.5).

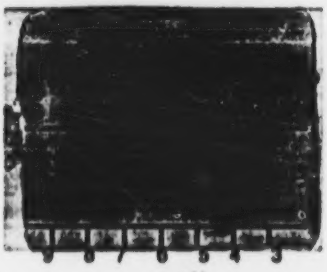


Figure 6. Electrophorectic titration curve of fraction 11 using an IEF 3-9 Polyacyramide gel (Pharmacia BioTech). Fraction 11 (Fig.5) was the fraction with the highest specific activity and the most hemorrhagic fraction. The total protein applied to the IEF 3-9 gel was 0.00009 mg. The gel was then placed into the Pharmacia Phast System for separation and development (Phast Silver Kit Instruction Manual 11-B-080-09).

DISCUSSION

ET is an excellent indicator of the results of HPLC. As an analytical tool, ET has become an invaluable asset in predicting the separation protocol of crude *C. atrox* venom by ion exchange chromatography. ET provides a method for evaluation of the surface charge ratio of the components of crude venom. By assessing the varying surface charge of proteins, the optimal protocol for purification can be determined. By reviewing the migration pattern of the bands an optimal range for separation can be visualized. In addition, ET provides a great deal of supplementary analytical data. By assessing the electrophoretic titration curve, one can extract not only the optimal method for purification, but also, the acidity or basicity of a sample at a given pH. It is also relatively simple to ascertain the pI of the sample. The purity of a sample can likewise be determined by the number of bands present in the gel. Electrophoretic titration can also be used in conjunction with other types electrophoresis such as two-dimensional electrophoresis to further identify components of interest. The use of electrophoretic titration has become an important procedure in the purification scheme of crude *C. atrox* venom. The use of this powerful tool aids in predicting isolation of a "pure" hemorrhagic toxins that can be further studied. Following each purification procedure, ET was useful in selecting the next HPLC purification protocol. The purification of proteins is essential in understanding their function. With a purified protein, models can be constructed and the function of the protein can be determined. ET provides a method for determining optimal separation procedures when the choice of separation is dependent on the charge of the proteins.

Once a hemorrhagic factor is isolated, the mechanism for its activity can be reviewed. It is essential in the purification of the toxins that specific activity is not lost as this ensures that the toxins isolated have not be denatured, and that they are still capable of causing proteolytic activity. Acquiring a "pure" toxin will enable not only the production of monoclonal antibodies which can be used to find better treatment for the victims of snakebites, but it will also provide a means to study the proteolytic activity of metalloproteinases. The isolation of the hemorrhagic factors, anti-hemorrhagic factors, and the production of monoclonal antibodies will allow for study of the mechanism of the proteolytic properties of venom. Understanding the mechanism of activation or inhibition of metalloproteinases will also aid in the comprehension of proteolytic properties of some cancers.

Heavy metal contamination of lakes and streams is a common result of mining activity. Understanding how biological communities respond is critical for developing strategies to minimize the impact of such disturbances. We are developing methods to identify major functional groups of bacteria that may reside in metal contaminated freshwater sediments. These techniques use Denaturing Gradient Gel Electrophoresis (DGGE) of PCR amplified ribosomal gene fragments to discriminate among taxa likely to influence metal biogeochemistry. In addition to providing information on the ecology of these environments, our techniques may reveal bacterial strains or consortia that may prove useful in bioremediation.

BACKGROUND

The Coeur d' Alene river valley of northern Idaho was the site of a silver mine from the late 1800s through the 1960s. During this time there were few regulations on mining procedures and as a result, the south fork of the Coeur d' Alene river in addition to adjoining lakes were inundated with ore rich in trace elements. Within the delta where the Coeur d' Alene river enters Coeur d' Alene lake, total metals comprise approximately 15% of the sediment by dry weight. Many of these metals such as zinc, lead, and cadmium are at such high levels that they may pose a threat to many organisms should they leach into the water column. Microbial biogeochemistry plays a major role in the cycling of these metals. Environmental changes such as dredging or anoxic conditions resulting from eutrophication have the potential to alter microbial reductive activities allowing higher and potentially dangerous concentrations of these metals to move into the water column. Due to the danger posed by these sediments as well as their use as a model for understanding metal biogeochemistry, this system has been chosen to visualize how biological communities respond to these disturbances and determine strategies to minimize the impact of such disturbances.

To assist in this study we are developing methods to identify major functional groups of bacteria that may reside in these metal contaminated sediments. With advances in technology, new and better procedures for determining the composition and location of microorganisms within complex microbial communities is now possible. Sequencing, flow cytometry, and denaturing gradient gel electrophoresis are some of the newer techniques providing additional information and insight into these diverse populations. While it is estimated that cell culture can only isolate and characterize approximately 20% of naturally occurring bacteria, these molecular techniques can potentially identify all microorganisms within these communities (Muyzer, De Waal, and Uitterlinden 1993).

Denaturing gradient gel electrophoresis (DGGE) compares the melting properties of double stranded DNA fragments isolated from organisms. The technique exploits the differences in hydrogen bonding that occurs between these discrete sequence fragments. Melting characteristics are determined by the base pair composition of these fragments, with G-C rich sequences giving a higher melting point due to the extra hydrogen bond shared between these bases. DGGE uses a formamide/urea mixture instead of an elevated temperature to break the hydrogen bonds and denature the DNA. By creating a polyacrylamide gel with a gradient of increasing denaturant it is possible to physically separate different DNA sequences based on melting temperature (Fisher, Lerman 1983). As the DNA moves through the gel it reaches a point at which the denaturant breaks the hydrogen bonds and the double stranded DNA fragment partially disassociates causing a restriction in its movement through the polyacrylamide matrix. This results in the formation of a band that corresponds to the melting domain of the DNA fragments.

In addition to providing a method of identifying organisms, DGGE relates other types of information as well. Because DGGE can utilize nearly any region of an organism's DNA it is possible to adjust the sensitivity and scope of this procedure (Costes, Girodon, *et.al* 1993). This technique could provide information on a variety of problems ranging from detecting point mutations within genes to classifying and understanding populations of organisms. In this case, we are developing techniques that utilize DGGE of PCR amplified ribosomal gene fragments to ascertain the distribution of functional groups of bacteria that are likely to influence metal biogeochemistry within the heavy metal contaminated sediments of the Coeur d' Alene river delta.

MATERIALS AND METHODS

DNA extraction and PCR: *Bacillus subtilis* (ATCC 6051), *Burkholderia cepacia* (ATCC 25416), *Escherichia coli* (DH5-α), *Desulfovibrio desulfuricans* (ATCC 7757), *Methylobacterium thermoautotrophicum* (ATCC 29096), *Clostridium sporogenes* (ATCC 3548), *and Methanobacterium organophilum* (ATCC 27886) were used as standard strains and positive controls. DNA was extracted from these standard strains using a revised Marmur procedure (Johnson *et al.* 1994). Community DNA was isolated from bacteria inhabiting the environmental sediment samples using an extraction method developed in our laboratory (Harrington *et al.* Submitted 1997). DNA from a small region of the 16s ribosomal gene was amplified using specially designed PCR primers. The oligonucleotides; primer 1 (32-mer) 5'-AGTGGCGAGCTCAGTGCCAGCAGCC-GCGGTAA-3' and primer 2 (53-mer) 5'-AAACTCAAAGGAATTGCCC-CCCGTGCCCCCGCCCCGGCGGCCGCCGGCGGGCG-3' (Gibco BRL), were used to amplify the 533 to 907 region (*E. coli*) and attach a GC clamp to the PCR product. The primers include Not I and Sac I restriction sites to allow the primers to be utilized in cloning experiments.

Figure 1: PCR product of *E. coli* standard showing the region of amplification, primer attachment, location of Sac I and Not I restriction sites, and GC clamp.

The concentration of the extracted DNA was determined by 260/280 nm spectrophotometric analysis. One unit of *Thermus aquaticus* DNA polymerase (Perkin Elmer) was added to 100 mM of primer 533 and 907, 2.5 mg BSA (Gibco BRL), 400 pmol dNTP, 150 mM magnesium chloride (Gibco BRL), 10X PCR buffer (Gibco BRL), and double distilled water in PCR tubes layered with mineral oil to prevent desiccation. The 50 µl samples were incubated in the 480 Thermocycler (Perkin Elmer) at 94° C for one minute followed by four cycles of 94° C for 30 s, 65° C for 30 s, and 72° C for 30 s. These cycles were followed by three cycles at 94° C, 60° C, and 72° C each for 30 s. The last cycle was repeated 25 times extending each cycle five seconds. The amplified material was then tested on a 1.0% agarose gel using a 1 Kb ladder and a negative control to confirm the presence of the 400 bp PCR products.

DGGE: The denaturing gradient gel apparatus (DGENE BIO-RAD) was operated under the following parameters. Temperature was maintained at 60° C with a thermally regulated 0.5X TAE (40 mM Tris base, 20mM sodium acetate, 1mM EDTA) buffer (BIO-RAD) throughout the experiments. Acrylamide stock solutions (6.5% acrylamide and 37.5:1 ratio of acrylamide-bisacrylamide) containing 30% or a 70% concentration of denaturant (7 M urea and 40% deionized formamide constitute a 100% concentration) were used to form 30% to 70% denaturing gradient gels. The gels were run for 6 hours at 300 V (~150 mA). Gels were loaded with 10 µl of PCR amplified DNA from the standard strains and 20 µl from the environmental samples. After electrophoresis the gels were removed from the apparatus and stained in glass distilled water containing ethidium bromide (0.05 µg/ml) for 30 minutes. The gels were transilluminated with UV light and then photographed with Polaroid™ 665 film.

DISCUSSION

Before this rapid detection method may be employed to study complex microbial communities it must be completely developed and tested. Several procedures and protocols have already been developed and are continuing to be optimized for use in this detection method. Our methods to extract community DNA from mining impacted sediments are providing template DNA for PCR experiments in high yields and purity. PCR primers and reaction protocols are yielding the appropriate size fragments from numerous bacterial groups as is evident by the smears exhibited in lanes 9-13 of the denaturing gradient gel.

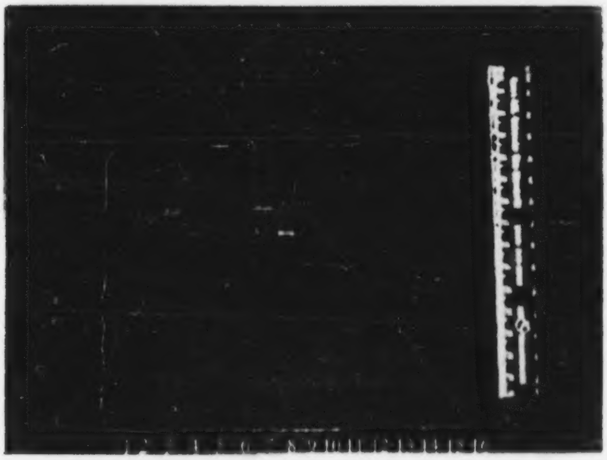

Figure 2: PCR-DGGE analysis of environmental samples: Lanes: 1 and 2, blank; 3, *B. subtilis*; 4, *B. cepacia*; 5, *C. sporogenes*; 6, *D. desulfuricans*; 7, *E. coli*; 8, *M. organophilum*; 9 to 13, environmental samples; 14 to 16, blank.

After multiple experiments, the parameters for resolving PCR products by DGGE have been refined. Work on transferring the DGGE gels to nitrocellulose membranes is currently underway. We have designed a sulfate reducing bacterial (SRB) probe which should hybridize to a portion of the 16s ribosomal gene fragment. The oligonucleotides will carry a chemiluminescent marker and are designed to recognize a majority of the bacteria that comprise this functional group (Risatti *et al.* 1995). After probing the membranes we hope to determine the distribution of SRB in these sediments. In addition, we plan to develop probes for iron reducing bacteria (IRB) and methane producing bacteria (MPB) to provide information on the major functional groups of bacteria that influence metal biogeochemistry in this environment.

This molecular detection method has the potential to provide results from sediment samples in approximately 48 hours; a rate far faster than conventional characterization techniques. It also has the advantage of examining nearly all of the bacterial strains in the environment as opposed to only those that are culturable. Besides its use for determining population

Purification and Biochemical Characterization of Antibacterial Antibiotics Produced by Soil *Streptomyces*

Faculty Advisors:

Dr. Robert W. Morris and Dr. Richard T. St. John

Antibacterial antibiotics produced by strains of *Streptomyces* isolated from soil samples were characterized using a modified Kirby Bauer antibiotic sensitivity screening procedure. Frozen spore suspensions of both narrow and broad spectrum antibiotic producing strains were inoculated into liquid culture and incubated with vigorous aeration for two weeks at 28 C. The resulting culture medium contained soluble antimetabolites that inhibited the growth of the same profile of bacteria as the original isolates did on the agar medium. The antimetabolites were purified by Sephadex column chromatography. The column fractions were assayed for antibiotic activity by transferring fractions to sterile filter disks employed in the Kirby Bauer assay. Chromatography data for one strain (ALD13) indicated activity in multiple fractions. These suggest that the strain produce more than one molecular species with antimicrobic activity. Further purification and characterization studies utilizing high performance liquid chromatography and nuclear resonance are planned.

BACKGROUND

Antibiotics are secondary metabolites produced by certain types of microorganisms, especially fungi and bacteria. In natural environments these antibiotics help the producing microorganisms compete against other organisms for limited resources. Clinically useful antibiotics have selective toxicity, that is they inhibit or kill certain types of microorganisms but are harmless to humans. Because of this they were considered medical miracles when discovered over half a century ago. The first antibiotic, penicillin was discovered by Sir Alexander Fleming in 1929 and became commercially available in the early 1940's. Streptomycin, the first "broad spectrum antibiotic was discovered by Selman Waksman in the mid 1940's. Since then hundreds of different antibiotics have been discovered and many are used to treat infectious diseases of man. For a time it was believed that the currently available antibiotics would continue to be effective. The reality turns out to be much different. Pathogenic microorganisms that once were destroyed by these antibiotics have now mutated and become resistant to many of these drugs. Recently there has been a revival of the search for new antibiotics and this area of research is being more generously funded.

Over fifty of the currently used antibiotics, (e.g., tetracycline and erythromycin) for the treatment of infectious disease in human as well as in veterinary medicine are produced by species of the soil bacterium *Streptomyces*. These bacteria are found in almost any soil and are relatively easy to isolate.

METHODS

The procedure that was followed for the preliminary isolation of the *Streptomyces* bacteria from soil samples was as follows:

- Soil samples were collected from the upper inch of top soil from various locations.
- The soil samples were dried at 37 C for one week.
- One gram of soil sample was diluted in 99 ml of sterile deionized water.
- A decimal serial dilution was performed.
- One tenth (0.1) ml portions of the 10^{-4}, 10^{-5}, and 10^{-6} dilutions were spread onto the surface of starch agar culture medium and incubated for two weeks.
- *Streptomyces* colonies were identified under a dissecting microscope and spores picked from the colonies using an inoculating loop moistened with sterile water. The *Streptomyces* spores were then streaked onto another starch agar plate and incubated at 28 C for 7-10 days.
- Agar plugs removed from the streak plate are employed in a modified Kirby Bauer assay to detect antibiotic production. The Kirby Bauer "test" microorganism was E. coli JM 103
- The Kirby Bauer plates were incubated for 24 hours and any zones of inhibition present indicate production of an antibiotic by the *Streptomyces* isolate.
- Once the antibiotic producing strain is identified, a 25% glycerol spore suspension is collected from the streak for use as long term storage at -20 C as well as for an inoculum for a broth culture.

The broth culture is then incubated in a water bath as 28 C and shaken at 280 rpm for 2 weeks. The broth is centrifuged and the supernatant passed through a vacuum filter membrane resulting in the removal of cellular debris. This filtered supernatant liquid was the 103rting material for the following assays that were performed in the process of biochemically characterizing the antibiotic molecule.

Gel column chromatography was employed for determining some of the properties of the antibiotic molecule. Five ml syringe barrels were used for the columns. The chromatographic column stationary phase gels employed were: Sigma's Sephadex G-10, a size separation gel that excludes molecules under 700 daltons; Sigma's Sephadex IRA 904, a strongly basic anion exchange gel; and Sigma's Amberlite 200, a strongly acidic cation exchange gel.

Tris Buffer (0.01M) was used and all columns were treated the same. The columns were first eluted with the Tris Buffer, then with 1M NaCl in 0.01M Tris Buffer, followed by a final wash of 0.01M Tris Buffer. One drop column fractions were collected onto sterile 12mm Whatman filter disks. These disks were then placed on Kirby Bauer plates inoculated with E. coli JM 103 as the test bacteria. In addition to gel column chromatography, this supernatant was treated with heat and with a series of different digestive enzymes and chemicals. An equal portion of both supernatant and enzyme were combined and treated under the same conditions.

The following experimental treatments were conducted on the culture supernatant containing antibiotic activity:

- Protenase K (a proteolytic enzyme routinely employed to remove proteins from nucleic acid preparations) at 55 C.
- Pancreatin (a digestive enzyme mixture containing amylase, tyrsin, lipase, ribonuclease and protease), at 40 C.
- Urea (with the intention of breaking H bonds if they were there). at 70 C.
- Finally, since many biological molecules are sensitive to alkali or acid, the pH of the supernatant was adjusted with the addition of HCl and NH_4OH.

These results are illustrated in the following tables (1 through 5).

RESULTS

TABLE 1. Effect of Proteinase K Treatment on the Antibiotic Activity of ALD13 Culture Supernatant vs. E. coli JM103 in the Kirby Bauer Disk Diffusion Assay

Additions to KB Disks	Diameter (mm) of Inhibition Zone
Culture Supernatant Alone (75 ul)	11
Culture Supernatant (37.5ul) Plus Proteinase K (37.5ul)	9
Proteinase K Alone (75ul)	0

TABLE 2. Effect of Pancreatin Treatment on the Antibiotic Activity of ALD13 Culture Supernatant vs. E. coli JM 103 in the Kirby Bauer Disk Diffusion Assay

Additions to KB Disks	Diameter (mm) of Inhibition Zone

DISCUSION

The antibiotic was somewhat retained on the anion exchange column, not retained on the G-10 size column, and completely retained on the cation exchange column.

Considering these results, we elected to investigate the antibiotic activity on a size column designed to retain molecules larger than 700 daltons. The next size in this Sephadex series is G-25 which excludes molecules 5000 daltons or larger and retains molecules below that limit.

The antimetabolite activity was not retained on the G-25 column. This data suggests that the antibiotic has a high molecular weight. The average weights of the currently known antibiotics are below 700 daltons. The apparent large size of ALD13 make it very unusual.

An alternative size determination method using millipore ultra filtration will be performed to support the data collected using the G-10 and G-25.

As evident in Table 1 by the size of the inhibition zones, treatment of the supernatant with Proteinase K at temperatures commonly used for nucleic acid preparations did not significantly diminish the antibiotic activity. This indicates that the antibiotic is not composed of or attached to a protein.

Treatment of the supernatant with Pancreatin also failed to destroy the antibiotic activity. Pancreatin contains a wide range of digestive enzymes yet none are capable of curtailing the antibiotic response. The only digestive enzyme group not represented is cellulase, which as the name suggests digests cellulose. Plans have been made to test this enzyme on the supernatant in the near future.

Table 3 illustrates the stability of the antibiotic at temperatures of 65 C for 2 hours. This treatment of heat just by itself would have degraded many proteins however again the supernatant is unaffected.

Results of Table 4 are similar to the previous treatments done, enough urea was added to the supernatant to bring the urea concentration to 6.0M and again no decrease in the size of the inhibition zone.

However when urea is added to the supernatant to a concentration of 6.0M and heated for two hours the antibiotic activity is destroyed. Urea treatment was used because it has the ability to break H bonds. However because it was a combination of heat and urea that destroyed the activity it could be pH related.

The last experiment that was run(not illustrated in tables) was to lower the pH of the supernatant to pH2 and raise it to 10. While the pH 2 had no adverse affects on the activity the pH 10 was also able to destroy the activity.

At this time no actual molecular sructure for the antibiotic has been suggested from the previous tests however the process is ongoing.

ACKNOWLEDGEMENTS

The author wishes to express appreciation to Dr. Frances Weaver and Dr. Linda Betz for their suggestions and ideas.

The role of substrates and grazers in the control of bacterioplankton were examined in a North Inlet tidal creek, in a 9-month study. The influence of substrates was examined by adding glycine or ammonium to the creek waters. The role of grazers was examined by size-fractioning the plankton by passing water samples through a 20 µm or 2 µm filtration apparatus. Bacterial response within these treatments was assessed by direct counting of bacteria and by measuring oxygen concentration over time-course incubations in dark bottles. The controls on bacterial activity (oxygen metabolism) varied seasonally, with substrate effects being minimal in the summer, a period of high oyster metabolism, maximal bacterial and phytoplankton abundances, and maximal water column nutrient concentrations. In contrast, in the winter, glycine additions greatly stimulated metabolism over all size-fraction treatments. Ammonium stimulated bacterial metabolism on only one date, and only in the < 2 µm treatment. A strong grazer influence upon metabolism was observed in the summer, when metabolism in the < 20 µm treatments exceeded that from the whole water or < 2 µm treatments. Grazer activity also was important in the winter, when bacterial abundances increased in all < 2 µm treatments compared to whole water. Factors controlling bacterial growth and production changed seasonally; both were primarily grazer-controlled ("top-down") during the summer but, in the winter, growth was grazer-controlled but, bacterial production was substrate-controlled ("bottom-up").

INTRODUCTION

Our understanding of the importance of bacterioplankton in aquatic environments has increased rapidly since the important works of Williams (1981) and Azam et al. (1983). Studies of bacterioplankton production and distribution in estuaries and coastal areas provide evidence that bacteria greatly influence carbon cycling processes by assimilating photosynthetically produced dissolved organic matter (Chrost & Faust 1983, Iturriaga & Zsolnay 1983, Azam et al. 1994), and serving as an important food resource for heterotrophic flagellates and ciliates (Sherr & Sherr 1977, 1994, Fenchel 1982, Wright & Coffin 1983a, b, 1984). Bacteria also can be both major mediators of NH_4 remineralization (Coffin and Sharp 1987; Hopkinson et al. 1989) and responsible for the assimilation of a large proportion of available nutrients into particulate matter (Wheeler and Kirchman 1986; Horrigan et al. 1988, Kirchman 1994). It appears that bacterioplankton can function either as remineralizers or assimilators of nutrients with their exact role dictated by the biochemical characteristics of their substrates. For example, both Goldman et al. (1987) and Hopkinson et al. (1989) showed that gross growth efficiency and the efficiency of bacteria in NH_4 remineralization are highly dependent upon their physiological state and the C:N ratio of the available bacterial substrate.

Ducklow and Peele (1988) further emphasized the importance of bacteria in estuaries, showing that bacterial production and biomass may exceed those of autotrophic assemblages plankton reveal that the majority of oxygen consumption occurs in the bacteria-sized fraction; in fact, Azam & Hodson (1977) suggested that free-living bacteria could be responsible for up to 90% of total heterotrophic activity.

Although it appears that bacteria are of great importance in large estuaries, few studies have been performed to assess the role of bacteria in smaller nutrient-rich ecosystems such as salt marsh tidal creeks. The objective of this study therefore was to examine the seasonal influence of bottom-up controls (substrate limitations) and top-down controls (biomass removal and/or nutrient regeneration by grazers) upon bacterioplankton in a small tidal creek in North Inlet, SC. Work by Lewitus et al. (Limnol. Oceanogr., submitted) indicates that phytoplankton are limited by top-down controls in the summer and bottom-up controls in the winter in a neighboring tidal creek in the North Inlet estuary. Based upon their findings, it is hypothesized that bacteria will be controlled in a similar manner with top-down control during the summer and bottom-up controls in the winter.

METHODS

This study was a component of a NSF project (DEB-9509057) to examine the role of oyster reefs on the structure and function of tidal creeks in North Inlet Estuary, South Carolina. This estuary is shallow, marine-dominated, and pristine. Water samples were collected monthly from the mouth of a small tidal creek off the larger Clambank creek. Monthly samples were obtained from July 1996 to March 1997. Triplicate samples were taken within 30 minutes of low slack tide between 12:00 noon and 3:00 p.m. on each occasion. Upon returning to the lab, water from each carboy was size-fractioned into whole water, < 20 µm and < 2 µm treatments. Each of these size-fraction treatments then either received no added substrate (unamended) or received additions of either NH_4 (2 µM) or glycine (20 µM) producing 9 treatments. All samples were transferred into 300-ml Biological Oxygen Demand (BOD) bottles. Temperature, salinity, dissolved organic carbon (DOC), particulate organic matter (POM), and rainfall data (for the 7-day period prior to sampling) also were obtained for each sampling period.

The BOD bottles were incubated in the dark and time-course sampled for bacterial abundance and respiration (a surrogate for bacterial production). Fixed samples (1% glutaraldehyde) were taken for bacterial abundance from whole water unamended samples at 0, and from all treatments at 72 hours. The samples were refrigerated in the dark at 4°C until slide preparation (typically within 2 weeks). Bacteria were stained with Acridine Orange by the method of Hobbie et al. (1977), and filtered onto black 0.2 µm polycarbonate filters. Bacterioplankton abundance was measured by epifluorescent microscopy on an Olympus BMT microscope, using 100x magnification. Multiple fields were counted until 400 or more bacteria were recorded, and then bacterial abundance was determined using the formula

$$Ab = (b * 26.246) / v \qquad (1)$$

Where Ab is bacterial abundance (cells/ml), b is the mean bacterial abundance per reticule, 26.246 is the ratio of filtered area to reticule area, and v is the filtered sample volume.

Oxygen metabolism (respiration) was measured with a YSI 50B oxygen meter and YSI 5730 self-stirring bottle probe, that was air-calibrated prior to each measurement series. Time-course measurements of dissolved oxygen (DO) were obtained at 0, 3, 5, 7, 24, 48, and 72 hours in all periods, and in the winter and early spring months, additional sampling took place at 96, 120, and up to 144 hours (Dec. & Jan.). After each measurement from the 300-ml BOD bottles, ~2 ml of 0.2 µ particle-filtered water was added to prevent bubble formation after resealing the bottle. Metabolic slopes from each bottle were calculated by linear regression of dissolved oxygen versus time.

RESULTS

Bacterial abundance varied seasonally, with concentrations peaking in July (7.0×10^6 cell/ml), decreasing to a minimum in October (2.5×10^6 cell/ml), and increasing slightly thereafter to 3.8×10^6 cell/ml in March (data not shown). Bacterial abundance varied directly with temperature (Pearson correlation, $R^2 = 0.60$, $p = 1.83 \times 10^{-5}$). The 72-hr change in bacterial abundance varied seasonally, with < 2 µm concentrations lower than other size classes in Sept. and Oct., but higher in the other months (Fig. 1). Glycine addition significantly increased bacterial abundance in Nov. and Feb. only (Fig. 2).

Respiration rates of unamended samples also varied seasonally, decreasing by 5-fold from July to Dec. (Fig. 3). Summer respiration rates were greatest in the < 20 μm fraction, while rates in the < 2 μm were less than those from whole water. In contrast, size-fraction effects on respiration were absent in the winter. Substrate addition had little effect on respiration in the summer (e.g. glycine, Fig. 4). In the late fall and winter, however, substrate effects were observed, with glycine stimulation of all size-fractions occurring throughout this period (Fig. 4), and NH_4 stimulation occurring only in the Feb. < 2 μm fraction (data not shown).

DISCUSSION

Bacterial abundance in marine systems is a balance between grazing on bacteria and substrate supply (Ducklow & Hill 1985, Coffin 1984). In the summer, in North Inlet, substrates did not affect microbial growth or metabolism, but a significant size-fraction effect on bacterial abundance and respiration was found, with the lowest measurements after incubation derived from the < 2 μm fraction. This suggests that either most of the bacteria were attached to particles and/or that grazing was beneficial to bacteria ("positive feedback" by grazer-produced nutrients).

In the winter, we observed a different trend. After incubation bacterial abundance in the < 2 μm fraction was higher than whole water, implying that grazing was limiting bacterial growth ("negative feedback"). Glycine affected bacterial abundance in Nov. 1996 and Feb. 1997, when growth of the < 20 μm fraction, and to a lesser degree, < 2 μm fraction, increased in response to glycine addition. In the winter, there was a significant stimulation of bacterial respiration by glycine, indicating that bacterial production during this season is substrate-limited. This is consistent with the wintertime minima in NH_4 and DOM that characterize this system (Lewitus et al. subm.) The preference for glycine compared to NH_4 could be explained by considering the dual benefit of carbon and nitrogen uptake that occurs when utilizing glycine. Kirchman (1994) has suggested that amino acids may be more important nitrogen sources for bacteria in estuaries whereas NH_4 may be more important in the open ocean environments.

In Summary, seasonal changes in the mechanisms controlling bacterial growth and production were indicated by the contrasting effects of size-fractionation and substrate addition on bacterial abundance and respiration. In the summer, a time of intense microbial activity, bacterial numbers are high, their food sources (substrates) are plentiful, but their predators are also abundant. We found that, in the summer, bacterial growth and respiration were controlled by grazing (top-down) positive feedback. In the winter, a time of low substrate availability, bacterial growth was controlled by grazing (negative feedback), but bacterial respiration was controlled by substrate supply (bottom-up).

Efficiency of Latex Gloves as Barriers to Bacterial and Viral Pathogens

Erica Jo Hughes

Department of Biology
Southwest Texas State University
San Marcos, TX 78666

Faculty Advisors

Dr Robert McLean and Dr Carolyn Benjamin

Latex is commonly used in medicine to control the spread of microorganisms The purpose of this experiment was to illustrate the ability of latex to act as a barrier to both bacterial and viral transmission A sterile latex glove was placed in flasks containing either *Escherichia coli* or K1F bacteriophage Bacterial transmission from the interior to the exterior of the glove was indicated by an increased media cloudiness Viral transmission from the interior to the exterior of the glove was indicated by a decreased media cloudiness After a 24 hour incubation at 37 degrees Celsius, spectrophotometer readings indicated that neither *E. coli* nor K1F phage escaped experimental latex gloves After analysis of the experimental results, it can be concluded that latex is an adequate material for use in preventing the transmission of infectious diseases, if the latex is without punctures This experiment would be a good exercise to demonstrate to first year medical students the importance of using latex gloves in order to prevent disease transmission

INTRODUCTION

In the recent medical world, infection control has become extremely important in preventing the transmission of pathogens The Centers for Disease Control and Prevention (CDC) has formulated guidelines, known as universal precautions, for health care workers to follow to prevent the transmission of pathogens to other health workers, patients, or to one's self (Sulzbach 1996) Also, the Occupational Safety and Health Administration (OSHA) has formulated additional standards for the safety of health care workers and patients that are subject to periodical inspection (Sadovsky 1993) The World Health Organization (WHO) has responded to the risk of disease transmission worldwide (Fidler 1996) To implement the use of universal precautions, health care workers must use latex gloves, masks, surgical gowns, and hand-washing procedures on and between all patient visits

The discovery of the first infection control technique, hand-washing, was discovered in 1847 in Vienna by Dr Ignaz Semmelweis (Jarvis 1994) He observed that there was a decrease in the occurrence of disease among patients when they were treated with washed hands, opposed to hands that had not been previously washed

One of the most important materials in the practice of infection control has become latex Several medical and household products are made of latex, including gloves, adhesive bandages, catheters, dental dams, tourniquets, diaphragms, and condoms (Gold 1994)

In recent years, the general public has become more cautious about the quality of infection control practices of health care workers due to the publicity of several dentists and surgeons who transmitted Human Immunodeficiency Virus (HIV), Hepatitis B, and Hepatitis C to several of their patients Traditionally, politically unpopular groups, like homosexuals and intravenous drug users, have been associated with diseases, like AIDS and hepatitis It has been proven that HIV is a threat not only to these risky groups, but also to transfusion patients and children who are born to HIV infected mothers In addition, HIV has become an increasing concern to heterosexuals who have multiple partners or whose partner has multiple partners The evidence of the transmission of these diseases in a medical setting have lead to a public hysteria, causing the fear of even routine medical and dental procedures to be performed in some cases The first case to be publicized was Dr David Acer, a dentist who practiced in Florida who was accused of transmitting HIV to six of his patients (Breo 1993)

The hands, because of the frequency and variability of the people and objects that they contact, are of extreme importance in infection control Both OSHA and CDC mandate the use of hand-washing and latex gloves as a method to prevent the spread of infectious disease In this study, the ability of latex gloves in preventing the transmission of virus and bacteria was determined

METHOD

Luria-Bertani Broth (Difco, Detroit, MI) was prepared and placed in twelve 1000mL Erlenmeyer flasks to replicate the experiment and several test tubes One latex glove was then placed in each flask The test tubes and flasks containing the gloves were autoclaved for thirty minutes at 121 degrees Celsius at 15 psi All of the test tubes but one, which was set aside in the cold storage and used for the blank in the spectrophotometer, were then inoculated with *Escherichia coli* EV36 Of these test tubes, a few were inoculated with 1 mL of K1F bacteriophage solution The inoculated test tubes were allowed to incubate overnight at 37 degrees Celsius

The negative bacterial control was conducted by placing a sterile glove in sterile medium and incubating the flask to ensure the glove and media was properly sterilized (free of bacteria) The positive bacterial control was conducted by placing a punctured glove within the sterilized flask and medium to investigate whether bacteria could be transmitted through needlestick punctures in the latex gloves The viral negative control was conducted by placing sterile gloves in flasks which contained bacterial media to examine whether the gloves were sterile (free of viruses) The viral positive control was conducted by placing sterilized punctured gloves in flasks which contained bacterial media to examine whether viruses could be transmitted through needlestick punctures in latex gloves

The cultures used in the experiment were *Escherichia coli* EV36 and its bacteriophage, K1F These cultures were the generous gift of Dr Eric Vimmer, Department of Microbiology, University of Illinois at Urbana-Champagne

The flasks were then treated as follows Flask A (glove only- negative control), Flask B (bacteria in punctured glove- positive control), Flask C (bacteria in glove- test), Flask D (glove only with bacteria within the flask media- negative control), Flask E (bacteria and phage in punctured glove with bacteria inside the flask media- positive control), Flask F (bacteria and phage in glove with bacteria inside flask media- test) These flasks were incubated at 37 degrees Celsius overnight

Spectrophotometer readings were taken at 600 nm of the media within each of the flasks to compare their Optical Density(OD) readings to the blank Bacterial transmission through the latex gloves was indicated by an increased turbidity of the media in the flasks compared to the blank Viral transmission through the latex gloves was indicated by a decreased turbidity of the *E. coli* culture in the flasks compared to the negative viral control

RESULTS AND DISCUSSION

Optical densities of the cultures in the various flasks are presented in Figure 1

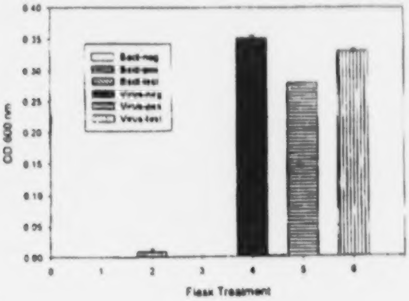

Figure 1 Optical Density of the media in the treated flasks

This experiment shows the importance of using latex in order to prevent disease transmission. Because this simple exercise demonstrates the importance of infection control so well, first year medical students would greatly benefit from performing this lab exercise as an introduction to the caution that must be taken to practice adequate infection control precautions while performing medical procedures

The negative control of the bacterial portion of the experiment shows that the media, flasks, and gloves were successfully sterilized, with no viable bacteria present in the flasks. The positive control of the bacterial portion of the experiment showed that, when the fingers of the gloves were punctured, bacteria were able to infect the media. This indicates that the occurrence of a needlestick during an invasive procedure allows for bacteria that happen to be present to pass inside and outside the glove, possibly infecting either the caregiver or patient. When a sterile, non-punctured glove is used, no bacterial transmission was observed. Both the caregiver and patient can be secure that infectious diseases will not be transmitted.

Some bacterial diseases that can potentially be transmitted through punctured or defective latex materials include tetanus, *Staphlococcus*, and Tuberculosis. Tetanus is a disease characterized by muscle stiffness and lock jaw. Tuberculosis is a respiratory disease caused by *Mycobacterium tuberculosis* in man (Miller and Farmer 1982). *Staphlococcus aureus* is a bacteria transmitted by touching meats that have been left out at room temperature for over five hours (Miller and Farmer 1982).

In the viral portion of the experiment, the negative control flasks show that the flasks and gloves had been properly sterilized: no viable viruses were present. The positive control flasks show the transmission of bacteriophage through the punctured glove. The phage infected the bacterial medium inside the flask causing the medium to clear. A decreased optical density was observed in this situation when compared to the negative control and test flask optical densities. This result clearly shows that when needlesticks occur, viruses can be transmitted either inside or outside the latex barrier, potentially causing either the caregiver or patient to be infected with the viruses present. To the contrary, when a non-punctured, sterile glove is used, little to no risk of viral transmission occurs. Latex reduces the risk of viral transmission.

Some viruses that can potentially be transmitted through defective latex gloves are Human Immuno-deficiency Virus (HIV), Hepatitis A, Hepatitis B, and Hepatitis C. HIV is the virus that causes AIDS (Acquired Immuno-Deficiency Syndrome), a disease which compromises the affected individual's immune system. AIDS leaves the individual with the inability to fight off common infections, such as the flu or pneumonia. Hepatitis causes inflammation of the liver and an increased risk of liver cancer. Huber (1993) claims that Hepatitis B is even more contagious than HIV in a hospital setting. Globally, 300 million people are infected with Hepatitis B (Lou and Wright 1993). 150,000 new cases of Hepatitis C occur in the United States only, omitting other countries (Brown et al. 1994). While Hepatitis B and C is transmitted through contact with blood and blood products, Hepatitis A is transmitted orally, by person to person contact (Miller and Farmer 1982).

Health care workers must be consistent in their practice of adequate infection control, as recommended by CDC and OSHA. Gould et al. (1996) stated that health care workers do not always wear gloves and handle sharp instruments safely. The reasons that have been stated by health care workers that do not always comply with the standards of universal precautions are forgetfulness, the belief that wearing gloves hampers their ability to perform procedures efficiently, and mere habit (Sulzbach 1996). Caregivers, who practice infection control as a method of self-protection instead of also practicing the protection of the patient, often work on multiple patients without changing gloves in between patient visits (Goldmann et al. 1996). These workers carry microorganisms from patient to patient, thus introducing infections to these patients by cross-contamination during procedures and to their surroundings. It is important to change gloves as often as possible, even when working on the same patient for a prolonged period of time, because gloves can be defective or become damaged by needlesticks or degraded by chemicals that are used for sterilization (Olsen et al. 1993).

To prevent the transmission of disease in the hospital setting, the public must become educated about infection control, universal precautions, and how diseases are transmitted. Patients should become aware of their surroundings in the health care setting and analyze whether adequate infection control is being practiced. Turk (1994) stated that patients should look for the following signs when performing an analysis on the infection control practices of health care workers that indicate adequate infection control is being practiced: a clean office, staff members who wear clean, freshly changed gloves, gowns, and masks, and the proper disposal of needles and other sharp instruments in labeled sharps containers.

The general public has become aware of infection control since 1990, when a dentist who practiced in Florida, Dr. David Acer, was accused of infecting several of his patients with

HIV. The media questioned whether Dr. Acer infected his patients with his own AIDS-infected blood accidentally or intentionally (Breo 1993). Furthermore, studies have shown that HIV can be acquired from a dried, contaminated surface for up to three days under certain laboratory conditions (Yim 1993). The Acer incident, along with public outcry, forced Congress to consider mandatory HIV-testing of all health care workers (Breo 1993). Despite the publicity, to date, no legislation has been enacted to enforce this mandatory testing. Since 1990, there have been several incidents where surgeons and dentists have been accused of transmitting diseases, like HIV and Hepatitis, to patients.

The possible transmission of bacteria and viral diseases, especially the deadly AIDS virus, through latex gloves has serious impacts on how society views the medical profession and the legal system. In the recent past, these diseases have affected numerous people, who have been denied items such as jobs, health and life insurance, and medical treatment (Jarvis et al. 1991). To avoid encroaching upon the ability of the many conscientious medical and dental professionals to perform their duties in the process of saving the public from the few professionals who do not follow the guidelines that CDC and OSHA has recommended, the general public must educate themselves on the principles of universal precautions.

Oysters can influence microbial food web dynamics in tidal creeks through negative (grazing) and positive (nutrient regeneration) feedbacks. Their effects should be a function of water residence time, and therefore oyster reef influence should be more strongly manifested in tidal pools than at the creek mouth. Nutrient concentrations, bacterial abundance, and phytoplankton biomass were compared at three sites within two North Inlet tidal creeks along the ebb tidal cycle. The creeks differed in morphology and hydrological properties. Creek A was larger and characterized by a greater neap tidal prism, greater total oyster biomass, but lower oyster density than Creek B. At low tide, spatial differences in NH_4^+, bacterioplankton, and chlorophyll *a* were found in creek B, with tidal pool chlorophyll exceeding levels at the mouth by >2-fold. In contrast, slight or no differences in these variables were found between sites in Creek A. Temporal variability in the above properties also differed between creeks, e.g. chlorophyll in the tidal pool increased ~6-fold from mid-ebb to low tide in Creek B, while in Creek A, no change was measured during the same period. That the enhancement of chlorophyll production in the Creek B, but not Creek A, tidal pool was due to the net effect of oyster reef activity (nutrient regeneration vs. grazing) is consistent with the greater oyster density and lower tidal volume exchange in the former creek. The results suggest that tidal pools can be sites of enhanced oyster reef impact on microbial food webs, but that the extent of oyster reef influence depends critically on tidal creek physical properties.

INTRODUCTION

Estuarine areas in the world are prime habitat for many species of bivalve mollusks, including the quahog clam (*Mercenaria mercenaria*), the American oyster (*Crassostrea virginica*), the ribbed mussel (*Geukensia demissa*), and the blue mussel (*Mytilus edulis*). The climate of the area decides the dominant species, e.g. oysters in warmer climates and mussels in cooler climates. In the southeastern United States the American oyster (*C. virginica*) is found in great abundance in the intertidal region of tidal creeks. These organisms affect both the physical and biological aspects of the creeks (Dame & Libes, 1993). As the oysters grow and reproduce, their dense aggregations form reefs and dams. These structures function as sediment baffles, and form tidal pools which increase the residence time of water parcels within the creek. Oyster reefs and dams provide shelter, protection, and food for a wide variety of organisms, including many species of polychaete and other worms, arthropods, fish, other mollusks, and crustaceans. In addition, the influence of oyster activities is felt by the microbial community. Oysters are filter feeders, grazing upon zooplankton, phytoplankton, and bacterioplankton (although with low efficiency) within the water column (Langdon & Newell, 1990).

Grazing, however, is not the only manner by which oysters and other bivalves affect the microbial community (Dame & Libes, 1993; Prins et al., 1995). As they feed and metabolize captured food, oysters release large amounts of remineralized, or regenerated, nutrients back into the water column. These regenerated nutrients, such as ammonium (NH_4^+) and orthophosphate (PO_4^{-}), are needed by phytoplankton and bacteria for primary production and growth. In addition, oysters release large amounts of dissolved organic matter (DOM),

1533

BEST COPY AVAILABLE

including dissolved organic nitrogen (DON). These substances help to support the bacterial population in the water column. Thus oyster activity can have a net positive effect on phytoplankton and bacterial growth within a tidal creek.

The goal of this study was to examine oyster reef impact on microbial food web dynamics in tidal pools versus other locations within tidal creeks. It was hypothesized that the effect of oyster reef activity on the microbial food web would be a function of the water's residence time within the creek, and therefore the magnitude of this impact would be greater in the tidal pools.

MATERIALS AND METHODS

Sample Sites

This project was a component of the NSF-funded study "The Role of Oyster Reefs in the Structure and Function of Tidal Creeks." Two tidal creeks in North Inlet Estuary (near Georgetown, South Carolina), differing in morphology and hydrological properties, were chosen for the study ("Creek A" and "Creek B"). Within each creek, three sites were sampled: the creek mouth, ~5 m inside the mouth, and the first tidal pool in the creek. A control site, Clambank Creek, midway between the creeks, was also sampled.

Creek A was the larger creek, with a bank full volume (BFV) of 2.8×10^{3} m^{3}, and a low tide volume (LTV) of 1.1×10^{2} m^{3} of water. The neap tidal prism, or average total volume exchange across the tidal cycle, was 2.7×10^{3} m^{3} (Corbett et al., unpublished). The oyster biomass in the creek was 7.6×10^{3} g/m^{2} (Anderson, unpublished data). The ratio of oyster biomass to bank full volume (OB/BFV) was ~3, and the OB/LTV was ~69.

Creek B was smaller, with a BFV of 4.0×10^{2} m^{3}, and a LTV of 16 m^{3} of water, a neap tidal prism of 3.9×10^{2} m^{3}, and an oyster biomass of 1.8×10^{3} g/m^{2} (Corbett et al., unpublished; Anderson, unpublished data). The OB/BFV ratio was ~5, and the OB/LTV ratio was ~115. Thus oyster population density in Creek B was relatively greater than that in Creek A.

Experimental Design

Samples were taken over the ebb tidal cycle on 30 July, 1996. Triplicate 120-ml samples for chlorophyll *a* and bacteria measurements were taken at each site at three tidal stages: high slack, mid-ebb, and low slack. Additional triplicate 120-ml samples were taken at each site for nutrient analyses. All samples were stored in the dark on ice until processed.

Nutrient levels (nitrate/nitrite, NO_2^-/NO_3^-, orthophosphate, PO_4^{-}, and ammonium, NH_4^+) were determined on filtered water (Whatman GF/F filter) using a Technicon AutoAnalyzer II (Glibert & Loder, 1977).

Ten ml of water from each sample was placed into a 15-ml centrifuge tube and fixed with glutaraldehyde for making bacteria and phytoplankton slides for direct counting by epifluorescence microscopy. For bacteria slides, 0.25 ml of sample was diluted into 4.5 ml of sterile-filtered seawater and 0.50 ml of Acridine Orange stain was added (Hobbie et al., 1977). The mixture was allowed to incubate for 1 min, after which it was filtered under low vacuum onto a 0.2 µm black polycarbonate membrane filter. The slides were then frozen until counting. For phytoplankton slides, 5 ml of undiluted sample was stained with 0.5 ml of DAPI, allowed to incubate for 5 min (Porter & Feig, 1980), and then filtered under low vacuum onto 0.2 µm polycarbonate membrane filters and frozen until counting.

For size-fractionated chlorophyll *a* (chl *a*) analysis, 60 ml of sample was used. Chl *a* concentrations were determined on whole water, and <20 µm and <2 µm filtrates, using a 20 µm sieve or a 2 µm polycarbonate membrane syringe filter. These values were then used to calculate the chl *a* concentrations for the following size ranges of plankton: >20 µm, 2-20 µm, and <2 µm. A freeze-thaw acetone extraction method was used to determine the chl *a* concentration (Glover & Morris, 1979), using a Sequoia-Turner Model 450 fluorometer.

Means were compared with a *t*-test with a significance level of 0.05.

RESULTS

Nutrient Levels

From mid to low tide a significant increase was measured in all nutrients in Creeks A and B, with NH_4^+ levels increasing greatly in both creeks (Table 1). In contrast, nutrients decreased during this same period at the control site, Clambank Creek. The lowest nutrient levels in Creeks A and B at low tide were in the tidal pools. NH_4^+ showed the most variation within the creeks, tending to decrease with distance into the creeks.

Low	10 ± 0.4	6.6 ± 0.2	5.2 ± 0.2				

Bacterial Abundance

Bacterial abundance in Creek A varied temporally, but not spatially (Fig. 1a). The pattern of bacterial abundance in Creek A over the tidal cycle resembled that of Clambank Creek, which ranged from ~8.0×10^6 cells/ml at high tide to ~1.2×10^7 cells/ml at low tide.

Creek B bacterial abundance increased from high to mid tide at all sites, but least significantly in the tidal pool (Fig. 1b). Values were equal to control (Clambank) values at high tide, as is expected due to the homogeneity of the water column at high tide, but thereafter remained lower. The bacterial abundance in the tidal pool remained lower than other sites within the creek. This corresponded to a significant increase in nanoflagellate plankton at the site (see below).

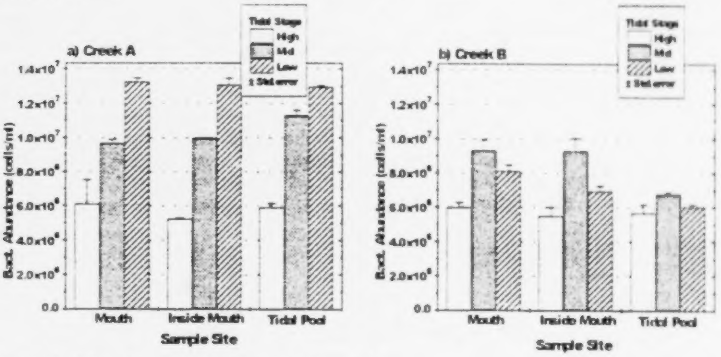

Figure 1: Mean bacterial abundance in the creeks

Chlorophyll Concentrations

Chl *a* concentrations at Clambank Creek increased steadily over the tidal cycle, ranging from ~10 $\mu g/m^3$ at high tide to ~35 $\mu g/m^3$ at low tide (Fig. 3a). Whole water chl *a* concentrations in Creek A showed little spatial or temporal variation (Fig. 1a). In Creek B, whole water chl *a* concentrations decreased from high to mid tides at all sites, but exhibited rapid increases at all sites from mid to low tides (Fig. 1b). The magnitude of this increase was greatest in the tidal pool, where nearly a 6-fold increase in chl levels was measured. At high tide, the largest fraction of whole water chl at all sites was in the > 20 μm range (Fig. 3). Along the tidal cycle, the 2-20 μm size fraction increased substantially, and by low tide comprised the largest proportion of the chl content in the creek. A dramatic (~ 16-fold) increase in this size fraction occurred from mid to low tide in the Creek B tidal pool (Fig. 3e), which corresponded

BEST COPY AVAILABLE

to a significant increase in phototrophic nanoflagellate abundance from 5.3×10^3 cells/ml to 9.0×10^4 cells/ml (determined by direct count). It is likely that this population increase was accompanied by an increase in heterotrophic bacterivores, which may explain the observed decrease in bacteria (see above).

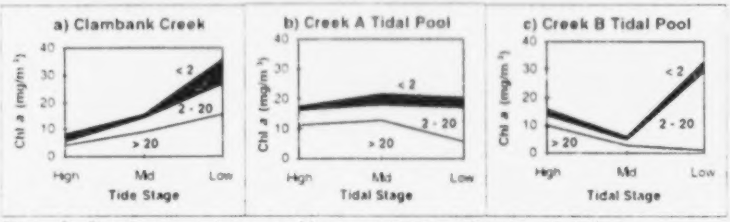

Figure 3: Size-fractionated (in µm) chl *a* concentrations relative to whole water.

DISCUSSION

Clambank Creek vs. Tidal Creeks

Nutrient levels in Clambank Creek decreased over the tidal cycle, in contrast to the tidal creeks, where nutrients were highest at low tide. These differences likely resulted from some combination of the following factors: 1) the greater resupply of nutrients by sediment resuspension in the tidal creeks, and 2) a greater influence of oyster reef nutrient regeneration in the tidal creeks. The decrease in nutrients from high to low tide in Clambank Creek coincided with increases in bacterial abundance and chl *a* concentrations, suggesting that nutrient uptake by these groups could explain ambient nutrient decline. Besides active growth at Clambank Creek, the increases in bacteria and chl *a* also probably resulted from the flushing of plankton-rich water from the tidal creeks.

Creek A vs. Creek B

Nutrient levels in the two creeks were similar at high tide due to the relative homogeneity of the water column in the estuary at that time. The increase in NH_4^+ levels in both creeks at mid-tide may have resulted from increased feeding by the oysters lining the banks as the plankton-rich water flowed out of the creeks on the ebbing tide. NH_4^+ is a major excretory product of oysters, therefore the higher nutrient levels in Creek B (especially NH_4^+), relative to Creek A, at nearly all tidal stages may be attributed to the higher oyster density in the former creek. The lower NH_4^+ level in the Creek B tidal pool, relative to the rest of Creek B, is consistent with phytoplankton uptake, as evidenced by the increased chl *a* levels at that site. According to Bishop et. al. (1984), NH_4^+ is readily utilized by nearly all species of phytoplankton and is the preferred form of nitrogen available for assimilation by phytoplankton.

Bacterial abundance in the two creeks at high tide did not vary significantly. In Creek A, bacterial abundance increased along the tidal cycle. In Creek B, bacterial abundance peaked at mid tide, and declined at low tide. No spatial variation was found in Creek A, while Creek B bacterial abundance decreased with distance into the creek, with the tidal pool having the lowest abundance at all tidal stages. The peak in bacteria at mid-tide in Creek B could be due to oyster phytoplankton and is the preferred form of nitrogen available for assimilation by phytoplankton.

Bacterial abundance in the two creeks at high tide did not vary significantly. In Creek A, bacterial abundance increased along the tidal cycle. In Creek B, bacterial abundance peaked at mid tide, and declined at low tide. No spatial variation was found in Creek A, while Creek B bacterial abundance decreased with distance into the creek, with the tidal pool having the lowest abundance at all tidal stages. The peak in bacteria at mid-tide in Creek B could be due to oyster removal of bacterivores. Oysters graze most effectively on particles between 3 and 10 µm (Newell & Langdon, 1996), which includes most bactivorous flagellates. The influence of oysters in reducing bacterivores in this size range is consistent with the reduction in the 2 - 20 µm fraction of chl *a* from high to mid tide.

Chl *a* concentrations in Creek A exhibited very little variation either spatially or temporally. In Creek B, the significant decrease in levels from high to mid tides could result from increased grazing pressure from oysters. The dramatic increase in levels from mid to low tide could have been a response to the high nutrient levels, presumably caused by oyster regeneration. The drop in the level of NH_4^+ in the Creek B tidal pool coincided with an increased level of chl *a* at that location, indicating an increased level of production.

CONCLUSIONS

The net result of nutrient and microbial dynamics was an increase in chlorophyll in the creek with relatively high oyster density (Creek B). The greatest stimulation was found in the tidal pool of that creek. These results suggest that tidal pools in estuarine tidal creeks can be sites of enhanced oyster reef impact on microbial communities in creeks of high oyster density.

Random genetic drift may play an important role in evolution, however there have been few studies of neutrally evolving regions in the human genome. Pseudogenes are assumed not to be under selective constraints. Thus, they are useful for studying the role of neutral evolution as well as for testing for selectionacting upon similar functional genes. Using 17 unrelated African-American individuals and three greater ape species: gorilla (*Gorilla gorilla*), chimpanzee (*Pan troglodytes*) and bonobo (*Pan paniscus*), variability was studied in the pseudogene HLA-H, located in the human major histocompatibility complex. SSCP (Single-strand conformation polymorphism) analysis was used to identify sequence variants. A portion of the HLA-H region of one or two individuals representing each variant SSCP pattern was sequenced and the data analyzed using two statistical tests: the McDonald-Kreitman test, and a test of substitution rates by codon position. The pattern of variability in HLA-H was not found to be significantly different from the expectations for neutral evolution.

INTRODUCTION

Darwin's theory of natural selection provided a mechanism for evolution: the maintenance of alleles in a population that increase an organism's fitness and the removal of those which decrease fitness. In the years since Darwin proposed the theory of natural selection, evolutionary biologists have proposed other mechanisms of evolution including neutral evolution. Unlike other processes, neutral evolution assigns chance an evolutionary role. The neutral theory of evolution holds that most mutations are selectively neutral, occur continuously and that by chance, some of these mutations will become fixed in the genome at a steady rate. Kimura (1968) argued that this type of evolution, the random fixation of selectively equivalent (or nearly equivalent) genes, accounted for the majority of changes at the molecular level. Neutral evolution may play an important role in the patterning of human genes. Pseudogenes can be used to study the molecular pattern of variability resulting from neutral evolution. Pseudogenes are once functional portions of the genome that mutations have rendered nonfunctional, and it is hypothesized that the genetic variability in pseudogenes should be patterned by neutral evolution (Li and Graur 1991). This hypothesis is based on the idea that the nucleotide substitutions present in pseudogenes reflect the pattern of spontaneous point mutations and cannot alter fitness because pseudogenes are not associated with an expressed gene product on which selection may act. Studies using pseudogenes are a powerful way to examine neutral selection alone as well as in comparison with other types of selection acting upon structurally similar functional genes to determine the type of selection acting upon these genes.

Such studies could be performed using the human major histocompatibility complex (MHC), also called the human leukocyte antigen (HLA) region. The HLA region of the short arm of chromosome 6 comprises 30 to 40 genes (Williams 1985) which code for proteins involved in various aspects of the immune response (Srivastava et al. 1985). Within the HLA region, the loci are grouped into three classes (Fig. 1). Class I genes, which include HLA-A, -B, -C, -E, -F, -G, -H, and -J (Messer et al. 1992) are located closer to the telomere than other classes of HLA genes and encode antigens which are expressed the cell surfaces of most nucleated cells (Williams 1982). The most extensively studied HLA genes are the highly polymorphic class Ia loci (HLA-A, -B, and -C) which are also called the classical loci, and are expressed on all nucleated cells (Klein 1986). Their gene products present foreign peptides to CD8$^+$ T cells for destruction (Quigstad et al. 1986). The less polymorphic class Ib (Klein 1986) genes in general have a more restricted tissue distribution (Hughes and Nei 1989). These nonclassical genes include HLA-E, -F and -G. Although some researchers believe those to be nonfunctional genes (Parham 1995), according to Grimsley (1997), HLA-E and -F show patterns of variation indicating the action of a selective force on a functional gene, and tests for selection acting upon HLA-G were unable to reject the null hypothesis of neutral selection. HLA-J is believed to be a gene fragment (Messer et al. 1992).

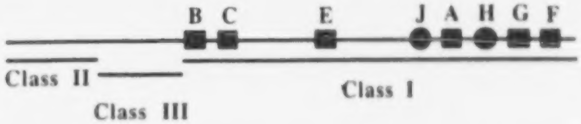

Fig. 1 HLA Complex Genes. This figure is not to scale. Squares represent functional genes, while circles represent pseudogenes or gene fragments. (Modified from Grimsley and Ober 1997)

Class II genes are highly polymorphic (Hughes and Nei 1989), have a much more limited distribution and are expressed in antigen presenting cells such as B cells, macrophages and dendrite cells (Williams 1982). These genes code for proteins which present foreign antigens to $CD4^+$ T cells (Quigstad et al. 1986). Class III genes code for complement proteins and other non-HLA peptides (Carroll et al. 1987).

The HLA region is among the most highly polymorphic in the human genome, with heterozygosity in some cases as high as 80 - 90% (Chomey 1990; Hughes and Nei 1988, 1989). The research of Hughes and Nei (1988, 1989) has supported the hypothesis of overdominant selection (heterozygote advantage) to explain the high level of polymorphism at some sites. They suggest that individuals heterozygous at these sites have a selective advantage over homozygous individuals because they produce more varieties of antigen-binding molecules, thus increasing their ability to respond to foreign antigens. In contrast to these highly polymorphic areas, other areas of the HLA region show higher levels of conservation (Srivastava et al 1985). Clearly, different selective pressures are acting within a small area on various HLA regions, allowing powerful comparisons between different selective mechanisms and neutral selection.

The pseudogene HLA-H is located between HLA-A and HLA-G (Fig. 1) in the class I region. It has the same eight exon structure which, in functional class I HLA genes, codes for a heavy chain with an extracellular portion, a transmembrane domain and a cytoplasmic tail (Williams 1985). Several authors have suggested on the basis of sequence homologies, that HLA-A, -H, -G and -J were all generated in several gene duplication events and that HLA-H was inactivated sometime after these events (Bjorkman et al. 1987, Chomey et al. 1990, Messer et al. 1992, Zemmour et al. 1990). Chomey et al. (1990) and Zemmour et al. (1990) have reported a frameshift mutation in human HLA-H which is created by a basepair deletion in the region corresponding to exon 4 in functional class I HLA genes. Upstream of this deletion, the amino acid sequence is different from that in functional class I HLA genes, and a premature stop codon is present near the end of the region, leading to the hypothesis that HLA-H is not functional (Chomey et al. 1990; Zemmour et al. 1990).

In addition, Venditti and Chomey (1992) reported that HLA-H was entirely deleted in some individuals with HLA-A23 or HLA-A24 alleles at the nearby HLA-A locus, supporting the hypothesis that HLA-H is nonfunctional. Chomey et al. (1990) obtained small amounts of HLA-H transcript, demonstrating that it retains a functional promoter. They suggested that if translated, an HLA-H protein would not interact with the phospholipid bilayer (as do other class I proteins) but would be secreted instead and could be linked to the cell surface by a phosphatidylinositol linkage. However, this translated protein would also lack a cysteine necessary for an intrachain disulfide bond present in all other class I peptides (Malissen et al. 1982). For these reasons, Chomey and et al. (1990) hypothesized that while the gene may still be functional in other primates it has been inactivated in the human lineage but that this inactivation occurred recently on an evolutionary time scale. Also supporting the hypothesis of recent inactivation is the one human HLA-H allele (HLA-12.4) without the frameshift deletion (Zemmour et al. 1990) which implies that the deletion occurred after the human lineage split from other primates. Hughes (1995) constructed phylogenetic trees of class Ia and Ib genes and several class Ia pseudogenes to study pseudogene evolution and presented further evidence that HLA-H is currently evolving neutrally but was acted upon by diversifying selection in the past and evolved from the duplication of a class Ia gene.

In this study, the hypothesis that HLA-H shows the pattern of variability characteristic of a neutrally evolving region was tested. Two current statistical tests were used which predict the patterns of variability present in a region under neutral selection: the McDonald-Kreitman test (McDonald and Kreitman 1991), which compares intraspecies polymorphisms to interspecies divergence and a test of substitution rate by codon position (Sawyer et al. 1987).

METHODS

Samples

Standard chloroform/phenol extractions (Bell et al. 1981) were used to purify DNA samples from 17 unrelated African American individuals who participated as controls in other studies (van der Ven and Ober 1994; Ober et al. 1989). Dr. Peter Parham, Stanford University, provided us with DNA samples from four chimpanzees and one bonobo. According to the "out of Africa" hypothesis of human evolution (Cann et al. 1987), Africans show the greatest amount of polymorphisms because they are the oldest human population, i.e., other races descended from an ancestral African subpopulation and emigrated from Africa.

SSCP (Single-strand conformation polymorphism) analysis

The amount of variation present in the region of HLA-H which corresponds to exon 2 in functional class I genes was determined using SSCP analysis (which is sensitive to single base pair differences) to identify sequence variants. In functional class I genes, exon 2 codes for the α_1 domain which forms part of the pocket that binds peptides and presents them to the T cell receptors (Williams 1985). Because pseudogenes do not code for a specific gene product, it is not correct to refer to exons and introns within HLA-H. For clarity, the region of HLA-H which corresponds to exon 2 in functional class I genes will be referred to as "exon 2".

SSCP analysis is based on the varying migration patterns in a non-denaturing polyacrylamide gel of short DNA fragments which differ by single point mutations (Orita et al. 1989). DNA samples were amplified by PCR (polymerase chain reaction) using primers designed for the intronic regions 3' and 5' of "exon 2" of HLA-H . Primer sequences were: H25, 5'-gacccagggagccgcgca-3', and H23, 5'-cggccctccgtgggggat -3'. About 0.5 µg template DNA was used for 10 µl total volume amplification reactions containing 2 pmol of each primer, 10 mM tris hydrochloride (pH 8.3), 50 mM potassium chloride, 1.5 mM magnesium chloride, 0.4 mM each dATP, dCTP, dTTP and dGTP, 0.5 units Taq DNA polymerase and 1 µCi ^{32}P-dCTP incorporated into the PCR product. After a PCR program of a 5 minute denaturation at 94°C, 30 cycles of denaturation (1 min at 94°C), annealing (1 min 15 sec at 70°C) and extension (2 min 5 sec at 72°C) followed by a 10 minute incubation at 72°C, 1 µl of the reaction was heated with 9 µl denaturing stop solution for 5 minutes at 94°C to denature the PCR product to single strands and then the product was chilled on ice. The strands were separated by electrophoresis on an MDE Hydrolink gel (FMC BioProducts, Rockland, Maine) at 8 watts for 17 hours and bands were visualized using autoradiography.

DNA Sequencing

For each human variant SSCP pattern, one or two samples (whenever possible) were to determine the nucleotide sequences. Initial forward sequencing of samples was performed manually using ^{32}P-labeled 5' sequencing primer. Perkin Elmer's (Banchbug, NJ) Amplicycle sequencing kit was used for the dideoxy method of cycle sequencing with Taq DNA polymerase following the manufacturer's instructions. Bands were visualized using autoradiography. Reverse sequencing of samples was performed using Pharmacia's ALF automated sequencer. The same amplification reaction conditions scaled up to a volume of 100 µl were used with the following exceptions: the H25 primer was biotinylated for solid-phase sequencing, the reactions contained 3.75 units of Taq DNA polymerase and between 0.5 and 1.0 µg DNA for each PCR reaction. All sequencing reactions were performed using Autoload, a solid-sequencing kit (Pharmacia, Piscataway, NJ), following the manufacturer's instructions. The concentration of the binding/washing solution was increased to 4M NaCl, 20 mM Tris-HCl, 2 mM EDTA, the first binding step was increased to one hour, annealing was at 71 °C and extension at 43 °C. The "exon" 2 region in the pongid ape samples was sequenced using the same techniques with the following exceptions: 1 min 30 sec annealing at 68°C, and 2 min 30 sec extension.

Data Analysis

The first test performed was an analysis of substitution rates at the three codon positions which can be used to determine whether or not a gene is functional (Sawyer et al. 1987). This test compares the numbers of substitutions at different codon positions. In functional genes that are under the influence of purifying selection, the substitution rate by position is expected to be:

$$S_3 > S_1 > S_2 \qquad (1)$$

Where S_1 represents the number of substitutions at the first codon position, S_2 the number of substitutions at the second codon position, and S_3 the number of substitutions at the third codon position. Because of degeneracy of the genetic code, substitutions at position 3 alter the amino acid less often than those at position 1, while substitutions at position 2 alters the amino acid most often (Sawyer et al. 1987). The neutral expectation is:

$$S_3 = S_1 = S_2 \qquad (2)$$

Data from the 17 individuals was used and a Chi-squared analysis of variance performed to determine significant differences.

The McDonald-Kreitman test (McDonald and Kreitman 1991) compares interspecies divergence to intraspecies polymorphisms to detect adaptive evolution. The ratio of replacement substitutions (M_r) to silent substitutions (M_s) is calculated within a species. This ratio represents intraspecies polymorphism. The M_r to M_s ratio between two species represents interspecies divergence. The McDonald-Kreitman analysis tests whether the relationship between M_r and M_s is the same within the species of interest as between two species. This test allows predictions of neutral, balancing or purifying selection occurring at a specific locus by comparing interspecies M_r:M_s and intraspecies M_r:M_s. When balancing selection is acting upon the locus, the intraspecies polymorphisms will be maintained in the population (the intraspecies replacement to silent substitution ratio will be higher than the interspecies ratio). A higher interspecies replacement to silent substitutions ratio (more divergence than intraspecies polymorphism) indicates that purifying selection is occurring at the locus. The prediction for neutrally evolving regions is equal interspecies divergence and intraspecies polymorphism. This test assumes equal likelihood of all nucleotide substitutions and no recombination, but is robust to deviations from these assumptions.

To perform the McDonald-Kreitman test, the human sequences were compared to three greater ape species: gorilla (*Gorilla gorilla*), chimpanzee (*Pan troglodytes*) and bonobo (*Pan paniscus*). The chimpanzee and bonobo genes used in the comparison were sequenced. The published Gogo-Oko allele, which Lawlor et al. (1991) suggest may be the gorilla homologue to HLA-H, was used for the analysis between humans and gorillas. Fischer's Exact test (performed using JMP version 3.0.2) was used to determine significant differences ($\alpha \le .05$).

RESULTS

SSCP analysis of the 17 samples indicated 15 different patterns in "exon 2". Sequence analysis revealed 10 different sequences.

Substitution by codon position

In "exon 2" there were two substitutions at position 1, seven substitutions at position 2, and six substitutions at position 3. One of these second position substitutions resulted in a termination codon in one individual. This pattern does not differ significantly from the null hypothesis of equal numbers of substitutions at each codon position ($\chi^2 = 2.8$, d.f. = 2, $p > 0.2$).

McDonald-Kreitman test

Using the McDonald-Kreitman test, the comparison between gorillas and humans, between bonobos and humans and between chimpanzees and humans all failed to reject the null hypothesis of neutral evolution (Table I). For humans, the numbers shown in the table represent intraspecies polymorphisms, and the numbers shown in the table for apes represent interspecies divergence. Interspecies divergence was calculated by comparing one ape sequence to all human sequences and considered as fixed differences only those basepair replacements that differed between the ape sequence and all human sequences. *P*-values were calculated using Fischer's Exact test.

Table I Data for McDonald-Kreitman test

	Replacement	Silent	p-value
Humans	9	6	
Gorilla	11	2	.2213
Bonobo	2	1	1.000
Chimpanzee	2	2	1.000

DISCUSSION

Evidence for the status of HLA-H as a pseudogene includes the deletion of the HLA-H locus in individuals with certain HLA-A alleles (Venditti and Chorney 1992), and a frameshift deletion in "exon 4" which results in a garbled sequence from this point and a stop codon near the end of this "exon". The inactivation of HLA-H, however, is believed to have been a recent event, which occurred during human evolution (Chorney et al. 1990; Zemmour et al. 1990). Our data are consistent with the hypothesis that HLA-H is a pseudogene in the human lineage.

Based on the results of the codon position test and the McDonald-Kreitman comparisons between humans and three primate species (gorillas, chimpanzees and bonobos), the null hypothesis that HLA-H is evolving neutrally cannot be rejected. In addition, the premature stop codon in the middle of one allele of "exon 2" is consistent with HLA-H being a neutral gene. For this reason, HLA-H may be used to represent neutral selection acting at a specific locus in comparison with nearby functional genes.

Interestingly, the p-value for the McDonald-Kreitman comparison for gorillas versus humans was much lower (0.2213) than the p-values (both 1.000) for bonobos versus humans and for chimpanzees versus humans. Lawlor et al. (1991) present three possibilities for the Gogo-Oko allele: that it is a homologue to HLA-H, that it is a homologue to HLA-A or that it is another HLA-A related locus which is not present or has not been discovered in humans. The low p-value suggests that one of the last two hypotheses is more likely.

It would be interesting to sequence "exon 3" and "exon 4" of HLA-H as well to determine if they also show a pattern of variation characteristic of a neutrally evolving region. In functional class I genes, these exons encode the α_2 and α_3 domains. The α_3 domain interacts with β_2 microglobulin (Williams 1985) and is more conserved than the α_1 and α_2 domains. As well as the tests presented here, a comparison of variability patterns between "exons" would help clarify the type of selection acting on HLA-H. Studies of variability in other populations would describe whether HLA-H is evolving similarly in other human populations. Further sequencing of HLA-H homologues among a larger pool of non-human primates would reveal more about the pseudogene's evolutionary history.

ACKNOWLEDGEMENTS

We thank Marc Roy, Amy O'Neill, Yutan Getzler, Kelly Knudson, and Lakmini Weerakoon for carefully reading early drafts of this manuscript and offering many suggestions.

Restriction Endonuclease Analysis
# of Plasmid DNA from
Methicillin Resistant *Staphylococcus aureus*

Methicillin resistant *Staphylococcus aureus*, commonly referred to as MRSA, is one of the leading causes of nosocomial infections. A large number of techniques are used to distinguish among MRSA strains in hospital outbreaks. Restriction endonuclease analysis of plasmid DNA, (REAP), is one of the techniques that has been used extensively in MRSA outbreaks and is the focus of this research. Thirty six-strains of MRSA were isolated from infected patients from three different local hospitals in Western North Carolina and subjected to REAP analysis in addition to antibiotic susceptibility tests.

INTRODUCTION

MRSA bacteria are gram positive cocci that are responsible for a wide percentage of nosocomial outbreaks. Several studies have reported that as many as 30%-50% of physicians and nurses have colonization within their anterior nares with *Staphylococcus aureus* and 2% are colonized with MRSA (Zafar et al, 1995). Certain patients are predisposed to staphylococcal infections: among these are newborns, nursing mothers, burn patients, transplant patients, AIDS patients, leukemia patients, and surgical patients. Patient-to-patient transmission via the hands of personnel is the most common and important means of spread.

MRSA is one of the leading causes of nosocomial infections and the increased length of stay in isolation units greatly increases the cost for both the patient and the hospital. In one study, 84% of the excess cost attributed to MRSA infections was due to the prolonged stay in the hospital as a result of the infection process (Pfaller et al, 1991). MRSA began to emerge as a nosocomial pathogen in the USA in the late 1970s and it was noted early on that an outbreak in any given hospital was probably caused by one or two strains that spread throughout the infected institutions (Boyce, 1992). REAP analysis can also be a very effective tool in examining the quality of infection control measures within hospital facilities before a MRSA outbreak occurs. It has been estimated that intensive surveillance and infection control measures, which include focused microbiologic support, can reduce the rate of nosocomial infection by 32% (Pfaller et al, 1991).

MRSA epidemics are a sign of an infection control breakdown and REAP analyses, along with other techniques, are used to trace the carrier of the MRSA outbreak. REAP subtyping has been shown to be a useful aid in defining the epidemiology of nosocomial infections (Branchini et al, 1993). However, MRSA plasmid analysis has been widely criticized due to the plasmid content instability and the possibility for gaining or losing plasmids during an outbreak of a single strain. There are several other techniques that are commonly used to categorize MRSA, such as bacteriophage typing, antibiotype, and genomic DNA analysis (Sabria-Leal et al, 1994). Antibiograms and phage typing are commonly used for characterization of MRSA during epidemiological outbreaks, but antibiograms are frequently inadequate to accomplish the differentiation and phage typing requires an inventory of bacteriophages that is unavailable at most hospitals. Phage typing is also often uninformative and too slow for epidemiological work (Zuccarelli et al, 1990). This project explored REAP analysis in order to categorize the collected MRSA strains.

METHODOLOGY

MRSA Strains. Thirty-six strains of MRSA were obtained from infected patients from three local hospitals in Western North Carolina. Twenty-two strains came from the Mission-St.

Joseph Hospital complex in Asheville, NC, a 758 bed facility, the bacteria were labeled A1-A22 for easy identification. Nine strains were obtained from McDowell Hospital located in Marion, NC, a 65 bed hospital, the bacteria were labeled B1-B9. Five strains were obtained from VA Hospital of Asheville which is a 330 bed facility, the bacteria were labeled C1-C5.

The thirty-six bacteria strains were transferred to slants and incubated at 37°C for 24 hours. Samples of the bacteria were then frozen in 50% TSY and 50% Fetal Calf Serum at -70°C. Each bacteria strain was then tested for methicillin, oxacillin, and augmentin susceptibilities before their use in the study. The bacteria were incubated at 30°C for 48 hours and the antibiotic susceptibilities were determined by the Kirby-Bauer disk diffusion method (Bauer *et al.* 1966).

Plasmid isolation. Two different plasmid isolation methods were used to isolate the plasmid DNA. The first was a modified Holmes and Quigley method (Holmes *et al.* 1981) and the second was a modification of the alkaline lysis method (Zuccarelli *et al.* 1990). In the Holmes and Quigley procedure, the bacteria were grown in 5ml of TSB in 15ml centrifuge tubes and incubated overnight in a 37°C water bath. The bacteria were then pelleted by centrifugation at 5,000 rpm for 10 minutes and the pellets were suspended in 5 ml TE buffer (10 mM Tris 1 mM EDTA pH 7.5). The cells were again pelleted by centrifugation and resuspended with 350µl STET buffer and transferred to microfuge tubes. Then 10µl of lysostaphin (1mg/ml stock) was added to the bacteria, and they were incubated for 30 minutes in a 37°C water bath. The tubes were then placed in a boiling water bath for 1 minute and centrifuged for 10 minutes. A sterile toothpick was used to remove the coagulated mass of chromosomal DNA from the solutions. After the chromosomal DNA was removed, 2µl of ribonuclease A (10 mg/ml) was added to the microfuge tubes, and samples were vortexed and incubated for 1 hour in a 37°C water bath. The solution was then extracted with an equal volume of phenol and again with an equal volume of chloroform. The aqueous layer was saved each time and 35µl of 3M sodium acetate was added along with 1 ml of 95% ethanol, then the samples were held on ice for 10 minutes. The pellets were then obtained by centrifuging the samples for 5 minutes. The supernatant was discarded and the pellets were allowed to dry. The pellets were then resuspended with 50µl of sterile distilled water.

Another sample of plasmid DNA was then isolated by a modification of the alkaline lysis method. The bacteria were grown in 30ml of TSB overnight in a 37°C incubated shaker. Each bacterial sample was then carefully poured into a 50ml centrifuge tube and centrifuged for 5 minutes at 5,000rpm. The supernatant was then discarded and the pellet was resuspended in 1ml TE pH 7.5. The suspended pellet was then transferred to microfuge tubes and spun for 5 minutes. The pellet was resuspended in 0.2 ml TE pH 7.5 and then 10µl of lysostaphin was added and the bacteria were incubated in a water bath for 1 hour at 37°C. Then 0.4ml of 0.2 M NaOH, 1% SDS was added and the samples were held on ice for 10 minutes. After 10 minutes, 0.3 ml of a potassium acetate solution was added and the samples were held on ice for another 10 minutes and then spun in a cold centrifuge for 10 minutes. The supernatants were transferred to fresh microfuge tubes and extracted once with an equal volume of phenol and then extracted twice with equal volumes of chloroform. After the extractions, 2µl of ribonuclease A (10mg/ml) was added and the samples were incubated in a 37°C water bath for 15 minutes. The samples were then extracted with 1ml of 1:1 solution of phenol-chloroform. Then 0.1ml of sodium acetate (3M, pH 7.0) was added to each sample. The DNAs were then precipitated with 3 volumes of ethanol and stored overnight at -20°C. The precipitates were then collected by centrifugation and washed with 70% ethanol. The pellets were allowed to dry for 30 minutes and then dissolved in 25µl of TE pH 7.5.

Restriction enzyme digestion. Twenty-five microliters of each sample was then digested with 2µl of EcoRI enzyme (24 units) and 3µl of EcoRI 10X reaction mix and allowed to incubate for 1 hour in a 37°C water bath. The digested DNAs were then applied to adjacent wells on 0.75% agarose gels in 1X TBE buffer. DNA markers, 1-kilobase DNA ladders (Gibco BRL), were applied to the end wells in each gel and the gels were run at 80V for 60-90 minutes. Gels were stained for 10-20 minutes with 0.5µg/ml ethidium bromide in 1X TBE buffer. The gels were photographed on an ultraviolet transilluminater using Polaroid 667 film.

RESULTS

Of the thirty-six bacteria strains obtained, B7 was lost during the time span of the research. All of the remaining thirty-five bacteria samples were resistant to methicillin, augmentin, and oxacillin. The sizes of measured zones of inhibition are shown in Table 1. Some results from agarose gel electrophoresis are shown in Figure 1. No plasmid bands are dectectable in the lanes loaded with DNA samples from B3, B8, and B9. Fifteen other samples were similar and produced no detectable bands. In lane 5, which contained DNA from sample A11, 4 distinct bands of size 9, 7, 5, and 4.5 KB are visible. Two additional samples from the Mission-St. Joseph Hospital complex produced the same pattern with 4 bands of size 9, 7, 5, and 4.5 KB. One sample produced a pattern of 3 bands: 9, 5, and 2.5 KB. Lane 6, sample A13, contains a smear of DNA. Five additional samples yielded similar smears. While lane 7, sample A14, shows a smear, some distinct bands are detectable. In addition, five samples (not shown) produced a single band >12.2 KB. In our laboratory, restriction endonuclease analysis of plasmid DNA from local MRSA isolates was not very informative. While a few samples yielded distinct profiles, most samples did not.

TABLE 1. Properties of MRSA strains from local hospitals in Western North Carolina. Sizes in mm of measured zones of inhibition are shown for oxacillin, methicillin, and augmentin.

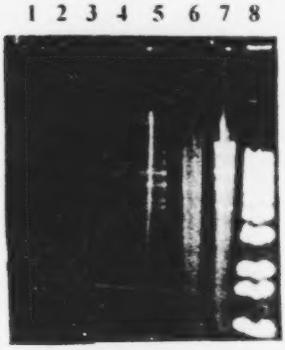

Figure 1. Agarose gel of restriction enzyme fragments of plasmid DNAs. DNA samples were loaded in lanes 1, 2, 3, 5, 6, and 7, which contain samples B3, B8, B9, A11, A13, and A14, respectively. A DNA size standard (1KB ladder, Gibco BRL) was loaded in lane 8.

DISCUSSION

Attempts to isolate plasmid DNAs and produce restriction enzyme fragment patterns met with little success. With the initial Holmes and Quigley plasmid isolation from 5 ml cultures, very few of the bacteria exhibited DNA fragments following agarose gel electrophoresis. Because of the low percentage of DNA bands obtained, the modified alkaline lysis method was employed. This method used a 30ml TSB sample to produce more plasmid DNA. The initial experimental procedure with this method called for incubation for 30 minutes with lysostaphin. The first gels obtained with this procedure did not produce bands and a major concern was that the cells were not being lysed during this short incubation time. The incubation time was then doubled to 1 hour to increase cell lysis. The final resuspension was also altered from 50μl of TE pH 7.5 to 25μl in hopes of obtaining a more concentrated sample for gel analysis. These alterations were marginally effective.

There are certain requirements that must be met for REAP analysis to be effective. The bacterial strains under investigation must contain a plasmid and the plasmids must be sufficiently diverse so that independent isolates are likely to carry distinctly different plasmid DNA. For this to be an effective tool within clinical settings, plasmid profiling must be rapid, reproducible, inexpensive, and accessible to clinical laboratories.

The rich diversity of plasmids among MRSA suggests that there are mechanisms at work, perhaps involving conjugation, phage mediated contact, transduction, transposition, and site-specific or homologous recombination that are continuously generating new plasmid forms (Zuccarelli et al. 1990). For REAP analysis to be useful in epidemiological outbreaks, the rate at which these DNA reorganizations occur is important. Also, the specific plasmid profile of MRSA needs to remain consistent, at least during the infection and hopefully for the duration of a MRSA outbreak. This is very probable based on observations of specific digestion profiles that remained consistent in hospitals over a period of more than two years (Archer et al. 1983).

While attempts to use restriction enzyme analysis of plasmid DNA as a molecular tool to identify similar MRSA isolates were not very successful, better profiles might be obtained by more experienced personnel. Even though more specialized instrumentation is necessary, other molecular tools which analyze genomic DNA from MRSA samples might be more reproducible (Sabria-Leal et al. 1994).

Faculty Advisor:

Dr. John J. Tudor

Little is known about the genetics of the bdellovibrios. Therefore, the development of a map of the Bdellovibrio genome would serve as a stimulus for additional genetic studies and provide a framework onto which genetic data could be coordinated. Conditions were established for the extraction of high quality, unsheared genomic DNA from two prey-independent strains of Bdellovibrio and for embedding that DNA in agarose plugs. Genomic DNA in the agarose plugs was subjected to restriction digestion by rare-cutting restriction endonucleases. Macrorestriction patterns were determined using Pulsed Field Gel Electrophoresis (both FIGE and CHEF) using various voltage settings and switch times. Maximum genome sizes have been determined for the two strains to be approximately 2.07Mb. Digestion with Not I, Pme I, Asc I, and Pac I resulted in 21, 18, 16, and 13 fragments respectively. Ordering of these fragments was begun using Southern Blot analysis. Probes were constructed from fragments generated by cutting the Bdellovibrio genome with different restriction endonucleases.

INTRODUCTION

Bdellovibrio bacteriovorus is a ubiquitous, gram-negative bacterium that exists by preying on other gram negative bacteria. It attacks the cell wall of its prey, entering the periplasmic space where it grows, feeding on the biochemical products of the cell. Reproduction takes place within the periplasm and progeny are released upon lysis.

The development of Bdellovibrio bacteriovorus is complex and has been studied ever since the bacterium was discovered in the early 60's. The bacterium especially serves as a good test organism fort he study of gene expression during development (1). If the gene organization of the bacterium can be mapped, it would help to elucidate the role of specific genes during its development and possibly the development of other predacious bacteria. Physical genome analysis is one of the most productive steps in creating a genetic map since it provides initial information on the organization of the genetic information (3).

Macrorestriction mapping using restriction endonucleases has been used successfully in conjunction with Pulsed Field Gel Electrophoresis (PFGE) to construct physical maps for the chromosomes of E. coli, P. aureus, H. parainfluenzae, and B. cereus (4). The genomes of the bacteria are cut using rare-cutting restriction endonucleases to attain large pieces of DNA. The DNA is then separated using PFGE. With the use of PFGE, DNA molecules in the size range of 1Kb to 6Mb have been made possible to separate (4).

Four rare-cutting restriction endonucleases, Not I, Pme I, Asc I, and PacI have been successful in cutting the Bdellovibrio genome into relatively few fragments for analysis. Analysis of the macrorestriction patterns of these four enzymes has yielded an estimated genome size of 2.7Mb for the prey independent strains Sa109 and 109JA. Southern Blot analysis has been used to assemble preliminary data for the physical map. Further analysis is necessary.

MATERIALS AND METHODS

Cell Propagation

Axenic strains Sa109 and 109JA of the bacterium Bdellovibrio bacteriovorus were cultured overnight by shaking at 240 r.p.m at a temperature of 30°C. These strains were obtained from fresh stock cultures and transferred daily by inoculating 9ml of peptone and yeast extract, pH 7.2 (PYE) with 1ml of bacteria. Cultures were checked daily before transferring for contamination.

Preparation of Agarose Embedded Bacterial DNA

The 10ml cultures were then spun down at 8,000 r.p.m for 10 minutes at 4°C. The DNA was embedded in agarose by following the procedure of Kreuger, Marks, and Ihler (2) except that the DNA was embedded in rods not slabs. The spun down culture was washed 3X with 5ml of PBS. Each wash was centrifuged at 8,000 r.p.m for 10 minutes. Following the washes, the pellet was resuspended in 1ml of PBS and mixed with 1ml of 2% low melting point agarose. The mixture was then pulled up into syringes and cooled to form the rods.

The rods were then removed from the syringes and soaked overnight in 5ml of proteinase K solution (1% SDS, 1mg/ml proteinase K, 1X TBE) to lyse the cells. While being soaked in proteinase K solution, the rods were shaken at a temperature of 50°C in a shaker water bath. The proteinase K solution was removed and the rods washed 10X with 5ml of 1X TBE (54g Tris base, 27.4g boric acid, 20ml .5M EDTA) while being shaken for 10 minutes. The rods were then washed 2X with 3ml of acetone while being shaken for another 10 minutes. Finally, the rods were washed 5X with 5ml of 1X TBE and simultaneously shaken for 10 minutes. The rods were then stored in 1X TBE until used for digestion.

Digestion of Agarose Embedded DNA

For digestion with restriction endonucleases, plugs ranging in volume from 10ul to 30ul were cut from the rods and placed in microfuge tubes. Three washes with 100ul of the appropriate buffer were performed before the enzyme was added. Depending on the digestion, the incubation time and the amount of enzyme varied. Conditions for digestion were based upon information presented by New England Bio Labs. Plugs were digested in 100ul of the appropriate buffer. Digestion times were minimal, ranging from 2 to 4 hours. After digestion, the enzyme was stopped by the addition of 1ml of 10mM EDTA.

Gel Electrophoresis and Analysis

Digested plugs were run on 2 electrophoresis apparatae, the LKB Pulsaphor 2015 CHEF and the PPI-200 MJ FIGE. The gels were made to a final concentration of 1% agarose using Fast Lane agarose in .5X TBE buffer. Cold circulating buffer was run through the chambers. The buffer was kept at a temperature of 4°C. The conditions for each gel run varied to obtain the best results. Optimal running conditions for the FIGE were 150 volts for 24hrs on PGM 4. For the Chef, the best patterns were achieved using pulse times varying from 10 to 60 seconds and voltages between 120 and 200 volts. After completion of electrophoresis, the gels were stained in ethidium bromide and analyzed using the Stratagene Eagle Eye II.

Probe Preparation

DNA fragments from different restriction digests were isolated from gels and labeled for use in Southern Blot analysis with digoxigenin by using the DIG High Prime Labeling kit from Boehringer and Mannheim.

Southern Blot Analysis and Hybridization

Gels were blotted onto positively charged nylon membranes by capillary treatment in 20X SSC (175.32g NaCl, 88.2g Na-Citrate, pH 7.0) and then were used in hybridizations. Hybridizations were performed according to the procedures of Boehringer and Mannheim. Membranes were subsequently stripped by boiling for 10 minutes in .1% SDS.

RESULTS AND DISCUSSION

Analysis of digestions from four different rare-cutting enzymes estimated the genome size to be about 2.7Mb for strains

BEST COPY AVAILABLE

Sa109 and 109JA. Digestion of the DNA with Not I produced 21 fragments that ranged in size from 5.80kb to 265.54kb (Table 1). The intensities of bands A, B, C, D, J, K, and L indicated the possibility that these bands were doublets (Figure 1). Digestions with Pme I yielded 18 bands that ranged in size from 18.13kb to 472.49kb (Table 1). Bands D, E, and J were also calculated as doublets due to their increased intensity compared to other fragments in the digest (Figure 1).

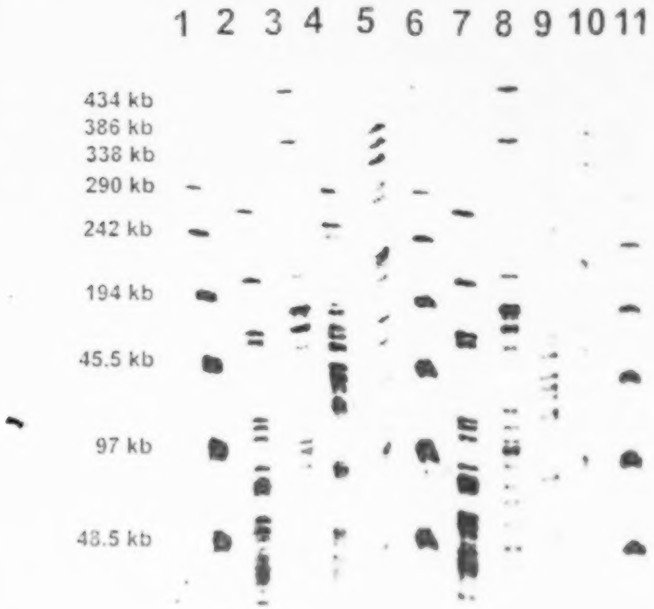

Figure 1: Not I, Pme I, Asc I and Pac I digests of Bdellovibrio DNA from strains Sa109 and 109JA separated by PFGE (CHEF). Lanes 1,6, and 11 Lambda Ladder; Lanes 2-5 Sa109; Lanes 7-10 109JA; Lanes 2,7 Not I Digests; Lanes 3,8 Pme I digests; Lanes 4,9 Asc I Digests; Lanes 5,10 Pac I Digests.

Maximum genome sizes estimated from the macrorestriction patterns generated by each of the enzyme are relatively consistent. Genome size calculated from Not I and Asc I digestions are about 200kb-300kb smaller than the genome sizes estimated by digestions with Pme I and Pac I. The presence of doublets in the patterns of Not I and Asc I digests other then those already indicated might reconcile the difference in size. Further PFGE analysis needs to be performed in order to determine the presence of doublets.

The macrorestriction patterns obtained for axenic strains Sa109 and 109JA with the rare-cutting restriction endonucleases, Not I, Pme I, Asc I and Pac I are very similar to each other. A similar banding pattern is produced by each enzyme in both strains of Bdellovibrio. This similarity in banding patterns suggests that Sa109 and 109JA are phylogenitically related to one another. The macrorestriction patterns generated by digestion with these enzymes can help to characterize these and other strains of Bdellovibrio and facilitate the creation of a phylogenetic tree.

Southern hybridizations at this point have revealed very preliminary results in construction of the physical map of the

Bdellovibrio genome. Trouble with high background on Southern blots that have gone through hybridizations and detections has prevented analysis. Work on reducing background and optimizing signal is in progress. With these conditions under control, the ordering of fragments can proceed by probing digests with fragments from other digests.

ABSTRACT

Gill and rectal gland tissue homogenates of the little skate *Raja erinacea* were examined to determine the types and amounts of transport ATPases present in the membranes. Tissue homogenates were treated with varying concentrations of different transport ATPase inhibitors and observed for changes in enzyme activity. Under conditions in which Ca^{2+}-ATPase and mitochondrial ATPase activity were inhibited, ouabain, an inhibitor of Na^{+}/K^{+}-ATPases, inhibited 93% of all remaining rectal gland activity whereas only 29.6% of all gill activity was inhibited. In contrast, *N*-ethylmaleimide, which inhibits proton ATPases, inhibited a greater percent of total activity in the gill tissues than in those of the rectal gland.

INTRODUCTION

Gill epithelial cells and a special regulatory organ known as the rectal gland are responsible for active uptake and secretion of Na^{+}, Cl^{-} and other ions in teleosts. Mitochondria-rich (MR) cells are present in gill epithelium and are the site for active NaCl secretion, a process catalyzed by Na^{+}/K^{+}-ATPase (Kultz and Somero, 1995).

Active transport can be selectively inhibited by certain blocking agents. The cardiac glycoside ouabain is a drug that selectively inhibits Na^{+}/K^{+}-ATPases while *N*-ethylmaleimide (NEM) inhibits H^{+}-ATPases. NEM-sensitive ATPase activity is also inhibited by other H^{+}-ATPase blockers such as DCCD and PCMBS, and also the plasma membrane ATPase inhibitor vanadate (Lin and Randall, 1993).

ATPase activity was measured in crude homogenates of skate gill and rectal gland tissue using a coupled-enzyme ATPase assay in the presence of EGTA, ouabain and azide (modified from Kultz and Somero, 1995, and Lin and Randall, 1993). Isolates of skate gill and rectal gland were examined to determine amounts of transport enzymes present. Experiments were performed at the Mount Desert Island Biological Laboratory in Salisbury Cove, Maine, during the summer of 1996.

MATERIALS AND METHODS

Prior to use, skates were removed from common pool holding tanks of sea water and a small incision was made between the eyes with a scalpel. The skates were pithed by the insertion of a wire through the incision into the brain and then down the entire length of the spinal column. The wire was then manipulated to effect destruction of the nervous tissue. The skates were taken to a running sea water holding tank where sea water was directed over the body and the gills were perfused to prevent drying and to keep the fish cool.

An incision was made on the ventral surface of the skate's body to expose the heart. The lower portion of the ventral aorta was then cut and a small plastic tube was inserted and tied into place with surgical thread. The fish was then perfused with heparinized, calcium free, Elasmobranch Ringer's Solution (ERS) consisting of 250 mmol l^{-1} NaCl, 6 mmol l^{-1} KCl, 3 mmol l^{-1} MgCl$_2$, 350 mmol l^{-1} Urea, 72 mmol l^{-1} Trimethylamine oxide (TMAO), and 8 mmol l^{-1} NaHCO$_3$ for 15 minutes to clear gills of blood (modified from Kultz and Somero, 1995). During perfusion the rectal gland was removed and placed into ERS on ice. The tissue was then scraped away from the gill arches using a scalpel, blotted dry and weighed. The rectal gland was also blotted dry and weighed and the data was recorded.

Gill and rectal gland tissues were each placed into 5 ml of homogenization medium which contained 300 mmol l^{-1} Sucrose, 2 mmol l^{-1} EGTA, 1 mmol l^{-1} Dithiothreitol, 100 mmol l^{-1} Tris-HCl, and 0.1% Deoxycholate (modified from Lin and Randall, 1993). The tissue was homogenized for one minute and then transferred to micro centrifuge tubes. The homogenate was centrifuged for one minute, the supernatant was removed, the pellet discarded, and the supernatant was either assayed immediately or frozen in a -80° C freezer until the day of the assay.

On assay day 0.9 ml ATPase reaction mix consisting of 30 mmol l^{-1} Imidazole, 125 mmol l^{-1} NaCl, 20 mmol l^{-1} KCl, 4 mmol l^{-1} MgCl$_2$, 5 mmol l^{-1} Na$_2$EDTA, and 0.4 mmol l^{-1} NaN$_3$ was added to a cuvette. The ATPase reaction mix contained azide, EDTA and was Ca^{2+} free in order to ensure complete inhibition of F-type (mitochondrial) and Ca^{2+} ATPase. Also added were 2 mmol l^{-1} phosphoenol pyruvate, 10 microliters LDH/PK enzyme mix (SIGMA), 1

BEST COPY AVAILABLE

mmol l^{-1} Na_2ATP, .5 mmol l^{-1} NADH, and either 25 or 50 microliters of rectal or gill tissue extract, respectively (modified from Kultz and Somero, 1995). Inhibitors used were ouabain, NEM, vanadate, PCMBS, and DCCD added in concentrations to yield 1 to 0.001 mmol l^{-1}. The tests were read for 5 minutes in a spectrophotometer at a wavelength of 340nm. There was an initial time delay of one minute to allow the solution to acclimate to 15^{o}C. Results are expressed as means ± standard error of means (S.E.M.).

RESULTS

Tests were run on 6 samples of skate gill and rectal gland tissue homogenates and enzyme activity on each control sample was measured before inhibition. A mean gill enzyme activity of 1.83 ± 0.285 umol mg^{-1} protein h^{-1} and a mean rectal gland enzyme activity of 12.1 ± 1.57 umol mg^{-1} protein h^{-1} were observed.

Ouabain (1 mmol l^{-1}) inhibited an average of 29.6% of all gill activity whereas 1 mmol l^{-1} NEM inhibited 23.7%. Vanadate was added in a concentration of 0.1 mmol l^{-1} and it inhibited 42.8% of all activity while 0.01 mmol l^{-1} PCMBS inhibited 24.4% of all gill activity (Table 1).

In the skate rectal gland it was observed that 1 mmol l^{-1} ouabain inhibited 93% of all activity and 1 mmol l^{-1} NEM inhibited only 19%. PCMBS, in a concentration of 0.01 mmol l^{-1}, inhibited 67.4% and 0.1 mmol l^{-1} vanadate inhibited 93.9% of all activity in the skate rectal gland (Table 2).

Table 1. Average activity (in percent) remaining after inhibition of crude homogenates of skate gill tissue

Inhibitor	Concentration (mmol l^{-1})	Remaining activity (%)	N
None		100	
Ouabain	1	70.4 ± 7.33	6
NEM	1	76.3 ± 5.07	6
Vanadate	0.1	57.2 ± 5.19	6
PCMBS	0.01	75.6 ± 6.22	6

Values are mean ± SEM

DISCUSSION

Our results support the conclusion that the bulk of the activity in the skate rectal gland was mediated by Na^+/K^+ ATPase as shown by the amount of ouabain needed to cause inhibition. In contrast, a substantial amount of the ATPase activity in the skate gill tissue was NEM-sensitive. The experiments were performed in the presence of EGTA, azide and ouabain to abolish any Ca^{2+}, mitochondrial or Na^+/K^+-ATPases in order to minimize the contribution of any unrelated ATPase activity. Therefore, the ATPase activity in the gill tissue that was NEM-sensitive was probably of the plasma membrane type. This is the first research of its kind to show the presence of any NEM-sensitive ATPase in the skate gill tissue. H^+-ATPase has been reported to be either bound to membranes or packaged in cytoplasmic vesicles. NEM is an alkylating agent that is relatively selective for sulphydryl groups (SH-) and inhibits vacuolar H^+-ATPase. The gill ATPase that was NEM-sensitive was also sensitive to vanadate. However, in the mammalian kidney, vanadate fails to inhibit NEM-sensitive activity which is believed to be mediated by vacuolar H^+-ATPase (Lin and Randall, 1993). Effects of Wood Frog (Rana sylvatica) Predation on Spotted Salamander (Ambystoma maculatum) Oviposition Site Selection

James W. Petranka

Wood frog (Rana sylvatica) tadpoles have been presumed to be herbivorous filter-feeders. They have recently been shown to possess the ability to shift to being upper-level carnivores, preying upon eggs and hatchlings of amphibians coexisting within the same pond community. Wood frog tadpoles have been documented to feed on spotted salamander (Ambystoma maculatum) eggs. Two experiments were conducted to determine the effect of wood frog tadpole predation in structuring communities as well as influencing the oviposition site of spotted salamanders. The number of egg masses deposited by spotted salamanders in experimental ponds with or without a standard density of Rana egg masses (0.6/m^2) was monitored. Later, spotted salamander hatchlings were added to these same ponds and tracked their survival.

Spotted salamanders did not exhibit avoidance behavior towards wood frogs when selecting breeding sites. Salamander larvae survival was not significantly affected by tadpoles, but several Rana-free ponds contained Bufo and Hyla tadpoles. The results of this and other studies indicate that R sylvatica tadpoles have both direct and indirect effects in structuring southern Appalachian amphibian communities.

INTRODUCTION

The structure of biological communities is determined by a system of complex interrelationships involving both biotic and abiotic factors (Wilbur 1972, Cortwright and Nelson 1990). Community structure changes in response to many different stimuli in very complex ways, often affecting, through an intricate chain of events, far more than is at first apparent. For example, the harshness of winter conditions may affect predator survival, which in turn may determine the population density of prey species the following spring (Cortwright and Nelson 1990). Body size and growth rate of amphibian larvae generally decrease in response to an increase in density (Cortwright and Nelson 1990). In response to reduced growth, the larval period is increased, and larvae are more susceptible to threats from predation, parasitism or pond drying (Wilbur 1972). Also, because salamanders tend to reproduce upon reaching a certain body size rather than a certain age, large body size and fast growth rate increase the likelihood of survival to sexual maturity (Wilbur 1972).

Competitive interaction among species in a community is not simply dependent on the total number of larvae present, but depends also on the identity and abundance of each species present (Wilbur 1972). The experimental addition of a foreign species to a temporary amphibian community by Wilbur (1972) did not simply eliminate one species and allow a free niche for the newcomer, but modified the growth curves of many of the native species. Thus, the entire structure of the community was affected. This and other studies showed that the impact of one species on a second competing species is dependent upon the density of both heterospecific competitors and conspecifics (Wilbur 1972).

The study of community structure has often emphasized the effect of competition and predation, taking into account the direct (lethal) effects of predators that reduce or eliminate a population, but ignoring a predator's potential indirect (nonlethal) effects. Recent research indicates that predators can have important indirect effects. Figiel and Semlitsch (1990) found that the introduction of predatory fish into a small pond caused salamanders to modify their behavior, reducing activity in open water areas and moving into protective leaf litter at the pond's edges. The leaf litter was presumably a more resource-poor environment. Because of this change in food supply and competition for food from the fish, the larvae declined in conjunction with a change in larval feeding activity. Grey treefrogs

(Hyla chrysoscelis) have developed an extended breeding season that, by spanning a range of seasonal conditions, may allow better survivorship at some point in the season when ambystomatid predators are absent or less prevalent (Resetarits and Wilbur 1989). Another way in which species composition of a community is influenced is evident when two species of prey coexist. The less preferable species enjoys a much higher survival rate in the presence of the preferred prey as the predator seeks out the latter first (Cortwright and Nelson 1990).

The selective pressures to develop effective anti-predator defenses are obviously great, as complete mortality can otherwise result (Petranka et al. 1994, Semlitsch 1988, Wilbur 1972). Some amphibian larvae have developed noxious secretions to protect themselves (Kats et al. 1988) and others have evolved mechanical defenses, such as the thickly coated egg masses of Ambystoma maculatum (Semlitsch 1988). A more recently discovered method is spatial segregation through adult choice. There is an increasing volume of data which suggest the importance of adult choice as an evolved predator defense mechanism. In certain species, adults detect the presence of predators prior to laying eggs and avoid these sites in favor of predator-free environments. Certain insects can detect fish using chemical cues (Petranka and Fakhoury 1991), and Hyla chrysoscelis individuals are able to detect different competitors and predators and discriminate according to the risk to their offspring (Resetarits and Wilbur 1989). Several amphibian species that live in habitats with fish are able to detect the presence of a fish predator by chemical means and modify activity to minimize contact (Kats et al. 1988, Petranka 1994). In an experiment by Kats and Sih (1992), streamside salamanders avoided ovipositing in stream pools with fish. Kats (1988) has suggested that predator avoidance by chemical means evolved in response to fish predation on amphibians, and a recent study by Petranka et al. (1994) showed that this response extends to non-fish predators as well.

Because choice of oviposition site plays such a primary role in the success of a species in the temporary pond amphibian community, it is logical that selection should favor females who are able to evaluate a site based on its suitability for successful hatching and growth of their offspring. Minimal contact with a predator, most effectively achieved through the evolution of avoidance behavior, should be selected for.

In western North Carolina two species, the wood frog (Rana sylvatica) and the spotted salamander (Ambystoma maculatum) exist sympatrically, and often coexist within a single pond community. Though wood frog tadpoles were presumed to be herbivorous filter-feeders, recent observations and research have shown that they possess the ability to temporarily shift, under certain conditions, to being very effective upper level carnivores (Petranka et al. 1994). Recent studies indicated that wood frog tadpoles will eat the eggs and hatchlings of American toads and will cannibalize their own eggs and hatchlings (Petranka et al. 1994). Unpublished studies (J. W. Petranka pers. comm.) also indicate that wood frog tadpoles feed on spotted salamander eggs. Rana sylvatica and A. maculatum also appear to compete for invertebrate food resources (Wilbur 1972).

Sexton (1994) reported that naive A. maculatum adults do not avoid fish based on olfactory cues when selecting sites for ovipositing, even though strong selection pressure exists. Sexton's experiment was conducted with individuals having no prior experience with fish, and it is possible that adults with larval experience with fish would exhibit an avoidance response. Two experiments were designed to examine the effects of R. sylvatica in structuring an Appalachian bog community, and the ability of A. maculatum to detect and avoid predators when selecting breeding sites.

BACKGROUND AND METHODS

Rana sylvatica prefers shallow ponds and pools and is an "explosive" early- season breeder. A single female may remain at a breeding site for only a few days, though the entire breeding season lasts through much of February in western North Carolina. Ambystoma maculatum favors temporary or semi-permanent ponds where fish are absent. They often share ponds with other ambystomatids and generally begin ovipositing in early March in western North Carolina. Females lay both clear and white egg masses. Clear masses are more vulnerable to predation from tadpoles than are white eggs (J. W. Petranka pers. comm.).

Research was conducted at Tulula Bog, a mountain bog located in Graham County in western North Carolina. In the late 1980's, development was underway to turn the site into a golf course. Before the project was halted, and then abandoned, much of the site was drained, leveled and cleared of timber. The area currently contains several fish ponds and vernal ponds, as well as many small depressions which house temporary pond communities.

BEST COPY AVAILABLE

Ambystoma avoidance - Experiment 1 was designed to determine the response of breeding A. maculatum adults to predatory R. sylvatica tadpoles. Ten pairs of fish-free vernal ponds were selected. The ponds in each pair were of similar size and depth, and within 20-30 m of one another. Pond dimensions were recorded and surface area calculated for each pond. In each pair, one pond was randomly selected and the average egg mass density observed for Tulula bog during 1995 (0.6 Rana egg masses/m^2) was established. Wood frog eggs were collected from various natural and man-made sites throughout the bog. Prior to the addition of wood frog eggs on 3 March, spotted salamander eggs were removed from all ponds. Ponds were inspected for salamander eggs during major breeding bouts throughout the month of March and the total number of masses deposited was recorded.

Effect of Rana sylvatica on community structure -The second experiment was designed to focus on the effect of R. sylvatica tadpoles on the structure of pond communities and also the survival of A. maculatum hatchlings when with R. sylvatica. The same pairs of ponds were used; therefore, R. sylvatica tadpoles were already present in all experimental ponds. All A. maculatum egg masses were removed from the ponds after breeding had ceased. In late March, A. maculatum eggs were collected from various sites in the bog and placed in several plastic wading pools to hatch. After hatching in mid-April, salamander larvae were added to all ponds at a density of 10 larvae/m^2. After 7 weeks, the survival of A. maculatum larvae was determined by sampling larval density with an open-bottomed can sampler. Ten samples were taken per pond. For each sample, an open-bottomed trash can was forced into the mud and larvae dip-netted until 5 consecutive sweeps yielded no A. maculatum larvae. The size of the salamander population for each pond was calculated. These netted salamanders were measured from snout to the back of the rear legs to determine the mean size of the animals in each population. In addition to A. maculatum, the presence of Bufo, and Hyla tadpoles was also recorded. Data were analyzed using

RESULTS

Experiment 1 - Data collected from nine A. maculatum breeding sites between 3 March and 29 March 1996 provide no evidence of discrimination in oviposition site choice, in regard to R. sylvatica presence (Figure 1). The total number of egg masses laid in control versus experimental ponds did not differ significantly (P=0.53). The number of egg masses laid per pond ranged from 0 to 6 in control ponds and 0 to 21 in experimental ponds, with a median in both pond types of 1 mass per pond. There was also no significant difference in the number of clear or white A. maculatum egg masses laid in control versus experimental ponds.

Experiment 2 - Data collected between 12 April and 10 June 1996 indicate that R. sylvatica predation has no significant effect on A. maculatum larval survival (Figure 2). Mean numbers of A. maculatum hatchlings caught per pond were 14.0 for control ponds and 12.5 for experimental ponds. Mean size of hatchlings was 19.1 mm for control ponds and 21.6 mm for Rana-free ponds. Survival and growth rates in experimental and control ponds did not differ significantly (P=0.77). Rana sylvatica predation of A. maculatum appears to be limited to the egg stage, as hatchlings coexisted successfully with tadpoles.

Field observation of spatial segregation - Several other species which are preyed upon by R. sylvatica showed complete spatial segregation. Bufo americanus or Hyla chrysoscelis tadpoles were never observed in a pond containing R. sylvatica. Hyla and Bufo eggs were present in all experimental ponds and ranged from 6 to 207 tadpoles per pond, averaging 131 tadpoles per pond.

DISCUSSION

Even though predation by R. sylvatica tadpoles on A. maculatum eggs might favor the development of an active avoidance behavior, such as adult choice of oviposition site, no such behavior is apparent. The surprising lack of avoidance behavior may result from constraints associated with oviposition sites available to A. maculatum. Large permanent ponds usually contain fish, which are very efficient predators of A. maculatum embryos and larvae. Fish have been known to cause 100% mortality in A. maculatum larvae (Ireland 1989). Fish-free options for oviposition available to A. maculatum are limited. Rana sylvatica tadpoles are also efficient predators of A. maculatum with greater than 90% mortality of embryos observed (J. W. Petranka unpub. data). Rana sylvatica is a prevalent species at Tulula Bog and lays its eggs in most suitable temporary ponds. This leaves very few ponds which are free of both fish and R. sylvatica tadpoles. Ponds which are free of both are often unsuitable because they do not retain water through A. maculatum's 4 to 6 month larval period. If A. maculatum avoided sites containing fish and R. sylvatica tadpoles when ovipositing they would be unlikely to find adequate breeding sites.

Ireland (1989) observed that the A. maculatum do not select breeding sites based on the probability that larvae will survive and Sexton (1994) found no evidence that of A. maculatum actively avoids breeding sites with fish. Petranka (pers. comm.) however, has observed that ponds containing fish rarely contain A. maculatum egg masses. Ambystoma maculatum may rely on other methods other than adult choice to avoid predators, such as returning to natal ponds. Strong philopatric tendencies have been observed in A. maculatum (Phillips and Sexton 1989, Shoop 1968). Consequently, the number of eggs laid in a pond should be proportional to the rate of premetamorphic survival in preceding years. In this scheme, A. maculatum would be ovipositing in the best possible sites, however, the pattern would be by a passive trial-and-error method, rather than active avoidance. Regardless of the mechanism, both produce spatial segregation from egg or larval predators such as fish.

Ambystoma maculatum may be buffered from local extinction by R. sylvatica because of recruitment from other populations and high adult survivorship. Females typically lay 150-200 eggs per season and live 10-15 years, with high adult survivorship (Woodward 1982, Whitford and Vinegar 1966). Ambystoma populations tend to follow a boom/bust pattern with survival from year to year and pond to pond varying greatly (Stenhouse 1987). Selection for a long life-span allows A. maculatum to occasionally have years with high juvenile recruitment (e.g. in years when Rana populations are small to offset years in which hatchling mortality is high).

Ambystoma also have egg masses which are resistant to predation, an adaptation Bufo and Hyla do not exhibit, perhaps because of the lack of suitable fish-free breeding sites. The white egg masses of A. maculatum are significantly less vulnerable to predation than the clear morph. There appears to be a positive correlation between R. sylvatica density and the percent of total egg masses laid which are white (Petranka unpub. data). Thus evolution of resistant egg masses, rather than adult avoidance behavior, appears to be another strategy used by this species to minimize predation risk to offspring.

Rana sylvatica predation affects amphibian communities in both direct and indirect ways. Ambystoma, Bufo, and Hyla all suffer the direct effects of predation when ovipositing in ponds containing R. sylvatica. Spatial segregation is among the many indirect effects of R. sylvatica predation. In response to egg predation, Hyla and Bufo have responded by developing the ability to detect and avoid R. sylvatica and other predators when selecting breeding sites (Petranka et al. 1994, Resetarits and Wilbur 1989).

In conclusion, R. sylvatica indirectly excludes Hyla and Bufo from ponds. It appears that the effects on A. maculatum are somewhat different. By way of direct predation, R. sylvatica may also indirectly exclude A. maculatum from ponds with low reproductive success. Ponds with low survival rates should lead to smaller numbers of returning adults to that pond the following year.

Direct effects of R. sylvatica predation on eggs is only one way in which the community is effected by R. sylvatica predation. These experiments add to the growing body of knowledge on the interaction and role of R. sylvatica in structuring mountain bog amphibian communities. They also confirm that tadpole's ability to shift to function as upper-level predators has much greater ecological consequences than was previously thought. Understanding the complex biological interactions occurring in this type of community will facilitate the restoration of this and other communities which have been damaged by human activity.

James W. Petranka

Wood frog *(Rana sylvatica)* tadpoles are microphagous filter-feeders. Nonetheless, tadpoles may prey upon the eggs and hatchlings of amphibians. Opportunistic predation by *R. sylvatica* tadpoles on spotted salamander *(Ambystoma maculatum)* eggs was examined. The jelly coat that surrounds the eggs of *A. maculatum* varies in color from milky white to clear. Populations in western North Carolina are polymorphic for egg mass color and the white morph occurs more frequently than clear or intermediate forms. In a wading pool experiment, food level, egg mass color, and tadpole presence was varied. Tadpoles significantly reduced embryonic survival of *A. maculatum*. When supplemental food level was low, egg predation rates were relatively high and clear egg masses suffered greater mortality than white egg masses. The data suggest that opportunistic predation by a primary consumer can result in high premetamorphic mortality. Tadpole predation appears to be one of several selection pressures maintaining egg color polymorphism in *A. maculatum*.

INTRODUCTION

Most tadpoles are considered to be microphagous suspension feeders that eat algae, fungi, detritus, and associated microorganisms. They have morphological adaptations such as well developed filter-feeding apparati and elongated guts for processing bulk quantities of low-quality food. Nonetheless, certain species that are morphologically adapted for filter-feeding prey opportunistically on the eggs of other anurans (Crump 1983, Petranka et al. 1994). In the present study, the significance of egg predation by wood frog (*Rana sylvatica*) tadpoles on the spotted salamander (*Ambystoma maculatum*) was examined.

In the southern Appalachians *R. sylvatica* breeds in late January through mid-March in temporary ponds. Breeding activity peaks in February and tadpole densities may exceed 2,000 tadpoles/m^2 when other amphibians arrive to breed later in the season (Biesterfeldt et al. 1993). Spotted salamanders often share breeding ponds with wood frogs. Females attach eggs to fallen tree branches or other supports in firm masses that are 5-15 cm wide and 5-25 cm long. Individual egg masses may have > 180 eggs and range in color from milky white to clear. In western North Carolina the white morph occurs more frequently than clear or intermediate forms.

Experiments were designed to address the following questions: (1) To what extent does *A. maculatum* suffer egg predation from tadpoles? (2) Does supplemental food level or intensity of intraspecific competition for food influence rates of egg predation? (3) Do white and clear egg masses differ in susceptibility to tadpole predation? (4) Do tadpoles play a role in maintaining egg color polymorphism? (5) Do tadpoles that feed on eggs benefit through increased growth or survival?

METHODS

Test for effects of food level and egg color on predation rates in wading pools.

A 2 x 2 x 2 factorial experiment was conducted using 0.9 m-diameter plastic wading pools to examine whether survival of *A. maculatum* embryos is affected by tadpole presence, food level, and *A. maculatum* egg mass color. The factors used were food level (low; high), egg mass color (clear; white), and *R. sylvatica* tadpoles (present; absent). The following levels for each treatment were established: (1) adding 3 g versus 9 g of powdered rabbit chow to each pool each week, (2) adding one clear or one white egg mass to each pool, (3) adding or not adding 800 *R. sylvatica* tadpoles to each pool. To determine if tadpoles that feed on eggs benefit through increased growth and survival, two additional treatments were included (800 *R. sylvatica* tadpoles and no *A. maculatum* egg masses at low and high food levels specified above).

Wading pools (N=50) were arranged in a spatial array consisting of five replicates of the 10 experimental conditions. Pools were set outdoors in an area that received direct sunlight. *Rana sylvatica* tadpoles were added on 28 March and *A. maculatum* egg masses on 30 March when tadpoles had developed to the feeding stages. The experiment was terminated 17 d after adding *A. maculatum* masses to the pools.

Eggs in clear masses could be accurately counted but those in white masses could not. Subsequently the relationship between the wet mass of egg masses and the number of embryos per egg mass was examined. Covariance analysis indicated that egg number determined from egg mass dissection was positively correlated with the wet mass of egg masses ($p = 0.006$), that the number of eggs per egg mass did not differ significantly between white and clear egg masses of similar wet mass ($p = 0.45$), and that the slopes for the regressions were homogeneous ($p = 0.27$). Based on these results, clear and white egg masses were matched in each replicate as closely as possible by wet mass, and changes in wet mass were used to estimate egg predation rates.

Egg masses and tadpoles (N = 10 tadpoles/pool) were weighed prior to adding egg masses to the pool, and after 7 and 14 d. The experiment was terminated 17 d after adding *A. maculatum* masses to the pools. After 14 d, most egg masses in one treatment (clear; low food) were completely consumed.

To determine if tadpole feeding activity varied among treatments, the number of tadpoles feeding on each egg mass was scored in late afternoon (4, 6, 7, 11, and 12 d after the start of the experiment).

Vulnerability of released embryos to tadpole predation

In this experiment, it was determined whether *A. maculatum* embryos that are released from masses prior to reaching the hatching stages are vulnerable to tadpole predation. *Rana sylvatica* tadpoles (N = 800) were placed in a wading pool and supplied with powdered rabbit chow until tadpoles reached Gosner stage 26. On test day, one *A. maculatum* egg mass was dissected. Then one embryo [Harrison stages 38 - 39 (Duellman and Trueb 1986)] was placed in the vicinity of feeding tadpoles. This simulated conditions that occur when late-term embryos escape from egg capsules that have been opened by foraging tadpoles. Embryos at these stages are capable of uncoordinated swimming for several decimeters.

RESULTS

Relationships between food level, egg color, and predation rates in wading pools.

Tadpoles began feeding on *Ambystoma* egg masses within a few hours after masses were added to wading pools. Mean wet mass of egg masses in treatments with tadpoles declined through the second week of the experiment. In contrast, mean wet mass in treatments without tadpoles increased over this period due to absorbance of water. In general, clear egg masses were more vulnerable than white egg masses to tadpole predation, and egg predation was greater when food level was low (Fig. 1).

The mean number of tadpoles observed foraging on eggs was significantly greater in the low food treatments ($p = 0.0002$) but did not differ significantly for either egg mass color ($p = 0.33$). Tadpoles grew significantly faster in high food treatments ($p < 0.0001$). However, feeding on egg masses did not increase tadpole growth rate (Fig. 2).

Predation on late-term embryos by tadpoles

Within 5 min after being introduced into the pool, 14 of 20 embryos were killed and consumed by foraging tadpoles. Tadpoles frequently attacked the abdominal region of embryos where yolk reserves are concentrated, and the release of body fluids triggered nearby tadpoles to feed frenetically on the injured embryos. Six embryos swam away after being attacked and survived > 5 min.

DISCUSSION

In the southern Appalachians, *R. sylvatica* appears to function as a keystone species structuring amphibian communities. Here, an adaptive value to white spotted salamander egg masses was identified. This study suggests that tadpole egg predation is an important factor maintaining the high frequency of white egg masses in vernal ponds in western North Carolina.

The number of tadpoles feeding on clear versus white eggs did not differ significantly, which suggests that protein crystals do not make white masses distasteful. However, white masses tend to be firmer in consistency than clear masses, particularly as the masses age and absorb water. This may present a physical barrier to the mechanics of grazing by tadpoles. Because most populations in the southern Appalachians are polymorphic for egg color, the selective advantage of white eggs may be context-dependent suggesting that clear eggs are favored under certain conditions (e.g., years when tadpoles occur at low densities).

The results indicate that egg predation rates can be mediated by food level and intraspecific competition. Differences in tadpole growth rates between low and high food treatments presumably reflect intraspecific competition for limited food resources (Wilbur 1976). Although the low food treatment stunted tadpole growth, small (hungrier) tadpoles caused greater egg mortality than larger tadpoles. This, along with data on the number of foraging tadpoles observed on egg masses, suggests that tadpoles switch to *A. maculatum* egg masses only when high quality food resources are scarce. The outer jelly coat has a high water content and is presumably a low-quality food source. However, symbiotic algae (Gilbert 1942) along with mucopolysaccharides and mucoproteins that occur in the jelly (Duellman and Trueb 1986) provide some nutritional benefit.

Although *A. maculatum* embryos are a high-quality food resource containing yolk reserves with high lipid and protein content, there is some question as to whether tadpoles that are not specialized for carnivory can effectively digest animal matter because they lack a well-developed, acid-secreting stomach. Tadpoles in treatments with eggs did not grow any faster than tadpoles without eggs. This may reflect the fact that only a single egg mass was used per pool. In a similar experiment in which four egg masses were added per pool, tadpoles that fed on eggs grew significantly faster than those that did not (A. Rushlow, unpublished manuscript). Thus, there may be evidence that tadpoles benefit through increased growth when per capita consumption of eggs is high.

THE ROLE OF VISUAL CUES IN DETERMINING RECOGNITION BEHAVIORS IN *POECILIA LATIPINNA* AND *POECILIA VELIFERA x POECILIA LATIPINNA*

Joshua Bradner and Jeannine Caesar

Fish species rely on the ability to recognize fish of similar appearance in an anti-predator behavior known as the confusion-effect. Either white mollies (*Poecilia latipinna*) or black mollies (*Poecilia latipinna* x *Poecilia velifera*), placed in the central chamber of a three chambered tank spent significantly more time in the compartment of the central chamber closest to fish of similar appearance as opposed to an empty chamber. However, when given a choice between a group of black mollies in one side chamber and white mollies in the other side chamber, the white test fish spent significantly more time in the compartment closest to the side containing the white mollies. When given the same choice, the black test fish spent significantly more time in the compartment closest to the side containing the black mollies. Therefore, both the white and black mollies demonstrated the ability to choose fish of similar appearance based on visual cues.

INTRODUCTION

For many animals, living in groups is a way of life that confers important fitness advantages. Group living may increase the probability of securing a mate, finding food, or evading predators. In an interesting phenomenon known as the confusion effect, animals in groups (ie fish schools or flocks of birds), have a reduced risk of predation when compared to solitary animals. The confusion effect theory holds that predators have a more difficult time isolating and targeting specific individuals within a group. Neil and Cullen (1974) showed that increasing fish shoal size decreased successful predatory attacks, and that this effect held for both ambush predators such as squid, cuttlefish, and pike, and chasing predators such as perch. For the three ambush predators, increasing shoal size appeared to produce hesitation behaviors, which may have been responsible for the lowered rate of successful attack. The chase predator appeared to switch prey targets more frequently with increasing shoal size, thus reducing the probability of making a kill.

One of the restrictions on the success of the confusion effect involves the morphological similarity of the individuals within the shoal. It has been shown that the presence of odd , or morphologically distinctive individuals within a shoal tends to decrease the success of the confusion effect (Landeau and Terborgh, 1986). Animals that stand out within the group are easily isolated and attacked by the predator. This suggests that the ability to recognize and school with fish of similar appearance would provide a selective advantage.

Accordingly, this experiment was undertaken to determine whether fish choose to associate with fish of similar morphological characteristics. Two distinct varieties of molly, white (*Poecilia latipinna*), and black (*Poecilia latipinna* x *Poecilia velifera*), were given opportunities to associate with fish of similar or dissimilar coloration based only on visual cues.

MATERIALS AND METHODS

Test Organisms

Groups of 50 black (*Poecilia velifera* x *latipinna*) and 50 white mollies (*Poecilia latipinna*) were housed separately in two 30 gallon aquaria(36" x 18" x 12"). Both varieties were obtained from local pet shops. Both test tanks and housing tanks were maintained at 20 C.

Test Tanks

Five standard 20 gallon all-glass aquaria (30" x 12" x 12") were converted into test tanks by adding glass partitions using silicon. Each test tank was divided into three chambers; left, right , and center. The left and right end chambers were completely sectioned off from the center chamber by siliconing glass partitions, each one 7.5 in. from opposite ends of the tank. The center chamber was partitioned into left and right compartments by siliconing opaque plastic partitions (7" x 10") 6 in. from each end of the chamber wall. These partitions allowed the fish to move freely through the center chamber, but did not allow the fish to view both left and right end chambers at the same time. The tanks were covered with opaque foam on the outside of the back, right and left sides of the tank.

Behavioral Assays

Tests were performed on a weekly basis, Monday through Friday. On Friday, all experimental fish were returned to the holding tank. Fish for the upcoming week were then chosen at random from the holding tanks and placed into the test tanks. Following a three day acclimation period, tests resumed on Monday. Tests were run once in the morning and once in the afternoon. During the 10-minute testing period, the time spent by a test fish in either the left or right section of the center chamber was recorded. Two eight week experiments ran in succession, one using black mollies as test fish and the other using white mollies as test fish. Assay 1: one test molly was placed in the center chamber with nothing in either the left or right chambers. Assay 2: one test molly was placed in the center chamber and four mollies of opposing color were placed in either the right (week 3) or left (week 4) chambers. Assay 3: one test molly was placed in the center chamber and four mollies of similar color were placed in either the right (week 5) or left (week 6) chambers. Weeks Assay 4: one test molly was placed in the center chamber, four white mollies were placed in one side chamber(week 7- right, week 8- left), and four black mollies were placed in the other side chamber. For trials in which mollies were held in end chambers an equal number of tests were run with mollies in the left and right chambers to correct for possible "tank effects."

RESULTS

There was no significant difference in the time spent by test fish on either side of the central chamber when both the left and right chambers were empty. When 4 fish of opposing color were added to either the left or the right chamber, their was no significant difference in the time spent by the white test fish on either side of the central chamber (Table 1). However, the black test fish spent significantly more time on the side of the central chamber closest the fish of opposing color when given the same scenario (Table 2). When 4 mollies of similar color were added to either the left or the right chamber, the test fish spent significantly more time on the side of the central chamber closest to the 4 mollies of similar color. When given a choice between a group of 4 white mollies in one side chamber and 4 black mollies in the other, the test fish spent significantly more time on the side of the central chamber closest to the 4 mollies of similar color. (Results for white mollies summarized in Table 1. Results for black mollies summarized in Table 2.).

DISCUSSION

Results from Assay 1 (for both white and black mollies) ruled out the presence of "tank variables" that could have affected other assays. Results from the second Assay were mixed. While there was no significant difference in the time spent by the white test fish on either side of the central chamber, the black test fish spent significantly more time on the side of the central chamber closest the 4 fish of opposing color.

In Assay 3, both white and black test fish demonstrated a pronounced tendency to recognize and group in close proximity to fish of the same color. In Assay 3, both white and black test fish spent significantly more time on the side of the central chamber closest the 4 fish of similar appearance. When given the choice between a group of white test fish and a group of black test fish, results from Assay 4 suggest that the test fish was able to choose members of similar appearance based on visual cues alone. The ability of fish to recognize fish that share the same color variety is presumably a very important aspect of anti predator defense amongst wild populations. The confusion effect principle behind schooling states that many predators seek individuals from amongst a population that have a conspicuous appearance and can easily be singled out from amongst the larger group (Theodorakis, 1989).

It is known that species from aquatic habitats use a variety of sensory means to recognize predators. Aquatic prey species often learn to recognize predators through chemosensory recognition (Chivers and Smith, 1994; Chivers, Wisenden and Smith, 1996). Paradise fish appear to recognize predators visually based on their antipredatory reaction to eyespots (Altbacker and Csanyi, 1990).

It appears that the association choices of fish in this experiment were made solely on the basis of visual cues. Phermonal cues, if they exist, were unlikely to have traveled through the siliconed glass partitions separating the chambers of the test tanks. Auditory cues, if they exist, were also unlikely to have affected these results. While we have no evidence of the production of auditory cues by mollies, the possibility exists that these fish make sounds. However, even so, it is unlikely that these sounds could have penetrated the glass barriers without being occluded by the sound of air bubblers in the tanks. Furthermore, if sound was responsible for the results obtained in this study, we must assume that white and black mollies produced different sounds. Again, there is no evidence for this from our experiment or from the literature.

The most reasonable interpretation of these results is that the mollies utilized visual cues to make association choices. These results are consistent with a study in which black and white convict cichlids (*Cichlasoma nigrofasciatum*) chose to associate with members of their own type in similar experimental tanks (S.P. McRobert, personal communication).

While this study shows a case of recognition and preference based on visual cues alone, there are many questions regarding the specific parameters of this behavior. First, this phenomenon needs to be demonstrated in wild-caught fish species. Mollies were used in this experiment due to their easily distinguishable color morphs, which are rarely found in the wild. It will be important to determine whether fish from natural communities have the ability to recognize and distinguish between different fish based on the subtle cues found in nature. Another future experiment may focus on the origins of recognition behavior. It is still not known whether fish learn to recognize similar individuals or whether the phenomenon is innate.

Other experiments may focus on the degree to which fish can visually distinguish fish of similar appearance. Recent studies on visual systems in fish may provide clues to this problem. It has been shown that fish have the ability to see certain wavelengths of ultraviolet light utilizing patterns undetectable by humans. (Hawryshyn, 1992) This is similar to the visual system of honeybees, who use UV patterns to distinguish flowers(Wehner and Bernard, 1992). Experiments using UV sensitive film may uncover patterns in fish that would remain unseen by the human eye. The ability to recognize and choose fish of similar physical characteristics may rely on these patterns.

The formation and coordination of animal groups results from natural selection acting upon the individuals within the group. In this study, evidence is presented that individual fish choose to associate with similar-looking fish, which may lead to benefits from the confusion effect. In this way, the activity of individuals results in school formation which, in turn, increases the fitness of the animals within the school.

The Effect of the Lipid Content of the Diet of Blue Crabs, *Callinectes sapidus*, on Osmoregulation

Sarah E. Hazzard

Department of Biology and Marine Science
Jacksonville University

Faculty Advisor:
Dr. Lee Ann Clements

ABSTRACT

Blue Crabs, *Callinectes sapidus*, increase phospholipid production in their gills to waterproof the cuticle and to better deal with drastic salinity changes. A high lipid diet for blue crabs may increase their tolerance to salinity changes. The crabs were acclimated to 30 ppt. Crabs were fed a high fat or a low fat diet. Crabs from each diet were placed in a lower salinity or remained at 30 ppt. Osmoregulation was examined by testing the osmolarity of the crab's blood with a freezing point osmometer. The lipid content of the diet had no statistically significant effect on waterproofing.

INTRODUCTION

Crabs can prevent an excessive absorption of water in a hypotonic environment by incorporating lipids into their exoskeleton. Kata and Kamemoto (1968) documented the importance of lipids in the cuticle, showing that incorporation of extra lipids was under hormonal control. Whitney (1974) demonstrated that when a crab is transferred to water with half the original salinity, there is an increase in phospholipid production in the gills.

Lipids are incorporated into the epicutical layer of the cuticle, which is responsible for permeability (Lockwood, 1967), and is formed in the later stages of the moulting process. Moulting takes place in five stages. Stage A is the post-moult period where the crab does not feed, but takes in excess water . During Stage B, the exoskeleton begins calcification. The crab still does not feed. Stage C is a period of tissue growth and the restoration of normal feeding. Stage D is the pre-moult stage where the pigment and epidermis are secreted. The crab no longer feeds in this stage. The last stage, Stage E, is ecdysis where the exoskeleton is shed (Lockwood, 1967). For this experiment, Stage D is the greatest concern because this is when the epidermis, the site of the incorporation of lipids, is formed. However, the crabs must be at Stage C at the beginning of the experiment so that they will eat the artificial food source.

If an increased production of lipids is beneficial to hyporegulation, then an increased diet of lipids should also be beneficial. If the hypothesis is correct, crabs in the treatments with constant salinity should maintain a constant blood osmolarity. Crabs in treatments with a drop in salinity are predicted to show a decline in osmolarity, but the osmolarity of those in the high fat diet treatment should decline less.

MATERIALS AND METHODS

Two types of artificial food were prepared for the crabs. The artificial food consisted of non-nutrient agar and commercially canned tuna fish packed in water, with blended chicken fat and skin added to produce the high fat diet. For every 25 grams of agar powder, 1 L of de-ionized water was added. For every 250 mL of agar solution, 42 grams of tuna fish was added for the low fat diet, or 21 grams of tuna fish and 21 grams of chicken fat was added for the high fat diet. The food was heated and blended until it formed a homogeneous mixture. The food was then be allowed to solidify in ice cube trays. Solidified blocks were stored in sea water to allow the food cubes to absorb water before they were weighed so that the weight of the food consumed could accurately be calculated. The lipid content was measured on triplicate of each diet using gravimetric estimation after extraction with 2:1 chloroform in methanol (Barnes and Blackstock, 1973).

Twenty four crabs, all male, were acquired from a local distributor (Atlantic Coast Sea Food). Twenty four aerated tanks were set up containing sea water at 25 ppt. Blue crabs are often cannibalistic (Warner, 1977); therefore, each crab was placed in a separate tank. The crabs were allowed to acclimate for one week, or until they progressed on to Stage D of the moulting process. This stage is evident by a sudden decline in eating, or by the appearance of a clear ring around the last segment of the swimmeret caused by an engorgement of blood under the exoskeleton to prepare for separation during ecdysis. Half of the crabs were fed the low fat food source and the other half were fed the high fat food source. The crabs were weighed every other day to determine the trend of their weight change as a way to monitor their health.

Twelve aquariums were changed to 15 ppt. The other twelve tanks remained at 25 ppt. Every other day for one week, salinity was monitored with a refractometer and the crabs were weighed. The amount of food consumed each day was monitored to ensure that both types of food were being consumed. Food consumption was recorded by weighing the food before it was put in the tank and again after 48 hours. This experiment was set up as a randomized block design with four blocks. Each block contained one crab of each salinity/diet combination: low fat/constant salinity, high fat/constant salinity, low fat/changing salinity, and high fat/changing salinity.

During the week, three blood samples were taken from each crab, once before the salinity was reduced, and twice afterward. A syringe was inserted at the base of the swimmeret, and 0.5 cc of lymphatic fluid was removed and frozen. The frozen blood samples were tested in a freezing point osmometer. This device records the osmolarity of the blood by analyzing the freezing point, which is a function of the quantity of water in the blood. For each sample, three readings were taken and averaged. Due to a high mortality rate caused by power outages, this experiment was performed twice: once in the summer and once in the fall. Minimal changes in the experimental design were implemented including having a control salinity at 35 ppt and a low salinity at 25 ppt.

RESULTS AND DISCUSSION

The gravimetric estimation indicated that the lipid content of the high fat food source was substantially higher than the low fat food source. The high fat diet was on average 5.07% lipid (± 1.98, N=3), whereas the low fat diet was on average 0.08% lipid (± 0.11, N=3).

To ensure that the summer and fall experiments were comparable, the conditions and behavior of the crabs in both experiments were compared. In both experiments, crab weight changes fluctuated so greatly that no pattern or relationship could be determined. All of the crabs ate in the summer and fall; however, the amount that was consumed was highly variable. This variation may indicate that the crabs were in different stages of the moulting cycle. The crabs ate generally less in the fall than they ate in the summer. All of the crabs still ate some food, which allows for the further analysis of the effect of the diet. To ensure that food consumption was independent of food type, the food consumption results were combined (Figure 1). This graph demonstrates that one food type did not consistently influence consumption.

To correct for the initial variation in osmolarity, the mean osmolarity results were adjusted to a percentage of the initial value (Figure 2). This reduced the variation in the treatments with constant salinity. Osmolarity dropped for both of the treatments with a drop in salinity regardless of diet. This trend was repeated in the fall (Figure 3). A repeated measures analysis of variance of the % Initial Osmolarity combining summer and fall data (Table 1) indicated that both time period and salinity were statistically significant, but treatment (P>F of 0.2497) was not statistically significant.

Table 1: ANOVA Table of % Initial Osmolarity (Repeated Measures)

Source	Nparm	DF	Σ Squares	F Ratio	Prob>F
animal#(treatment)	2	2	45.5735	0.5862	0.5601
time period	2	2	1312.4578	16.8812	<.0001
treatment	1	1	52.6764	1.3551	0.2497
salinity	1	1	2366.6462	60.8810	<.0001
treatment*salinity	1	1	12.0868	0.3109	0.5795

There are several implications of these results. They could indicate that the hypothesis was incorrect, but there are also other possibilities of why the results were different from the expected results. The lipid content of the crabs natural diet was not known; thus, the low fat diet could have had a significantly higher lipid content than their natural food source, or the high fat diet could have had a lower lipid content than the natural food source. The crabs may not have been in the stage of their moulting cycle where they would absorb and incorporate the lipids into their epicuticle, as indicated by the fluctuation in the amount of food consumed. The content of the diet may have been another problem. Also, the amount of protein in the diet was not considered. The possible decrease in protein in the high fat diet may have affected the blue crab's osmoregulation. Also, the experiment may not have run long enough for the lipids to become incorporated into the epicuticle.

CONCLUSIONS

The results indicate that there is no significant effect of lipids in the diet of blue crabs on osmoregulation. There are several possibilities why the original hypothesis may have been false. First of all, there may actually be no relationship between diet and osmoregulation. On the other hand, the crabs may not have been in the right stage of their moulting cycle to absorb and incorporate the lipids into their epicuticle. Another possibility is that the experiment did not run long enough for the lipids to become incorporated into the epicuticle. These issues can be explored in further studies.

Eva Koch & Laura Murry
Horn Point Environmental Laboratory, Cambridge, Maryland

ABSTRACT

The effect of UV-B radiation, on the morphology and physiology of marsh vegetation was studied *in situ*. Plots of *Spartina* intermixed with *Salicornia* were covered by screens with selective absorption in the UV-B range. Results were compared to control plots (without screens and screens transmitting all UV-B). The screened plots transmitted less ambient light leading to decreased concentration of UV pigments in *Salicornia virginica* and *Spartina alterniflora*. Also, *S. alterniflora* showed morphological change when covered. However, the effects of decreased UV radiation on marsh vegetation is unclear from the data of this study.

INTRODUCTION

Atmospheric studies have shown that a number of man-made gases have the potential to significantly deplete the ozone layer of the stratosphere (Tevini, et al. 1983). Among these, chlorofluorocarbons are the most detrimental. The depletion of the ozone layer leads to an increase of ultraviolet radiation at the earth's surface. As this depletion is an on going trend, biological processes will be increasingly unprotected from UV radiation and, thus, increasingly susceptible to its effects.

In terrestrial plants, UV-B radiation (218-315nm) was observed to affect photosynthesis through disruption of the electron transport system and pigment stability (Bornman, 1989). These effects result in species specific degradation of plant growth (Tevini et al., 1983; Post and Larkum, 1992; Tevini, 1994; Cullen and Neale, 1994; Nikolopoulos et al., 1995). Most work has been done on individuals and/or in controlled environments. Though various effects of UV may be finely quantified in such laboratory environments, *in situ* effects may not be determined; and thus, may not be connected to probable consequences in nature.

Most work on the effect of UV on plants has focused on terrestrial and aquatic vegetation. The effects of UV on plants inhabiting the sea-land interface (i.e. salt marshes and mangroves) have been ignored. These regions are of extreme ecological and economic importance to fisheries and inland properties. Marshes throughout the world are characterized by zones of flora colonization dependent on the degree of inundation. Specifically, genuses *Spartina*, *Salicornia*, and *Juncus* are found in marshes of both North and South America; more specifically, *Juncus roemerianus* and *Spartina alterniflora* are found in higher and lower salt marshes of the Chincoteague Bay, respectively. *Salicornia virginica* is also found throughout the marsh, widely adapting to the marsh environment through numerous micro-species (Noble et al., 1992).

The purpose of this study was to observe the effects of UV-B radiation on the morphology and physiology of marsh vegetation while providing preliminary data for a future global study of the effects of UV-B radiation on salt-marsh vegetation along a latitudinal gradient.

METHODS

This study was conducted *in situ* for six weeks near Greenbackville, MD, on the Chincoteague Bay marshland (38 00'N 75 23'W). Two areas of *Spartina alterniflora* with intermixed *Salicornia virginica* at different degrees of inundation were selected for study.

Natural UV levels were reduced at each site, *in situ*, by placing triplicate 1.5 x 1.5 meter Mylar films over the canopy. Mylar selectively absorbs UV-B but transmits UV-A and visible light; this property was quantified with a Hitachi spectrophotometer.

1931

Natural UV levels were reduced at each site, *in situ*, by placing triplicate 1.5 x 1.5 meter Mylar films over the canopy. Mylar selectively absorbs UV-B but transmits UV-A and visible light; this property was quantified with a Hitachi spectrophotometer.

Two sets of controls were established:

1) near ambient UV-B plots were established by covering similar (but randomly selected) areas with Aclar which transmits 90% of all UV and visible light (this was also quantified with a Hitachi spectrophotometer);

2) ambient UV plots were delineated but not covered.

Three replicates of each treatment (Mylar, Aclar, and No Cover) were placed at each site (high and low inundation) for a total of 18 treatments.

Light intensity was quantified with a Licor portable light meter on a sunny and clear day. Readings were taken at canopy height and averaged for each type of covering or lack thereof.

Nondestructive growth rate determinations and UV protective pigment analyses were made every two weeks in order to quantify morphological and physiological responses over time at different degrees of exposure. *S. alterniflora* were tagged and measured (plant height, leaf number, and leaf width) in order to observe morphological changes. Samples of *S. alterniflora* and *Salicornia virginica* were taken and stored on ice until analyzed at Horn Point Environmental Lab. The plant material was ground with a mortar and pestle, and plant pigments were extracted with 5ml of spectrophotometric grade methanol, followed by centrifugation for 10 minutes to pelletize plant fibers. The pigment extract was scanned for absorption between 190 and 700nm using a Hitachi spectrophotometer in order to quantify physiological changes in pigment concentrations (Post and Larkum, 1993).

Plant growth measurements were compiled, differences between treatments computed and averaged to each group's respective plot type (five or ten plants tagged per plot). Plant pigment analysis was averaged according to plot type and normalized to 1 in the 660nm range. Data was compared by plot type (in respective salt stress environments).

RESULTS

Plastic covering material (Mylar and Aclar) was found to pass expected wavelengths. Mylar absorbed wavelengths from the UV-B and UV-C regions of the electromagnetic spectrum while transmitting all wavelengths from UV-A through the visible regions. Aclar was found to pass all wavelengths of light from PAR through UV-B, absorbing some UV-C. See Figure 1.

Light intensity was reduced under plastic coverings by 10%, as compared to control plots without cover. See Figure 2.

Plant morphology data yielded normal seasonal growth under the no-cover conditions, while the salt-stressed-short-form of *Spartina* at the more inundated site showed enhanced growth in plant height under both Aclar and Mylar coverings. See Figure 3.

Plant pigment analysis of *Salicornia*, two weeks after initiation of treatments, showed chlorophyll levels to be identical in all samples, regardless of filter covering; while there is a difference between no-cover-plot results and covered-plots in the UV pigment region. Covered plots (Aclar and Mylar) demonstrate a reduction in UV pigment concentrations. See Figure 4.

Plant pigment analysis of *Salicornia* six weeks after initiation of treatment showed chlorophyll levels to be slightly separated for Aclar covered samples. This difference became more pronounced in the UV-B region. No-cover-plot-samples contained the highest amounts of UV pigment with Mylar-filter-samples containing the next highest amount of UV pigment and Aclar-cover-samples containing the lowest amounts of UV pigments. See Figure 5.

Plant pigment analysis of salt stressed (short form) *S. alterniflora* two weeks after deployment of filters shows chlorophyll levels to be identical in all samples, regardless of filter covering; while there is a distinct separation of no-cover-plot results from covered plots in the UV pigment region. Covered plots demonstrate a clear reduction in UV pigment amounts. See Figure 6.

Plant pigment analysis of salt stressed (short form) *S. alterniflora* six weeks after deployment of filters shows chlorophyll levels to be nearly identical in all samples, regardless of filter covering; while difference in UV pigment concentrations are observed.

BEST COPY AVAILABLE

No-cover-samples show the lowest amounts of UV pigment, followed by Mylar-filter-samples, with Aclar-cover-samples containing the most UV pigment. See Figure 7.

Plant pigment analysis of tall form *S. alterniflora* two weeks after deployment of filters shows chlorophyll levels to be identical in all samples, regardless of filter covering; while there is a distinct separation of no-cover-plot results from covered-plots in the UV pigment region. Covered plots demonstrate a definite reduction in UV pigment concentration. See Figure 8.

Plant pigment analysis of tall form *S. alterniflora* six weeks after deployment of filters shows chlorophyll levels to be identical in all samples, regardless of filter covering. Pigments in the UV region show minimal separation, with no-cover-samples containing the most pigment, followed by Aclar-cover-samples, with Mylar-filter-samples containing the least amount of pigment. See Figure 9.

DISCUSSION

The major accomplishment of this project rests with the experience gained with *in situ* testing of marsh vegetation utilizing thin plastic coverings and/or filters. A durable and fairly portable frame was developed to support the plastic films which lended itself to field adjustments for plant growth, plant measurements, and sampling. A long list of "bugs" developed and many were worked out, enabling future *in situ* work to progress in a less hindered fashion. Also, a good deal of experience was gained with valuable laboratory

BEST COPY AVAILABLE

techniques and data analysis. However, a longer period of time with which to completely analyze all data and run invaluable statistical studies of the data would have greatly aided in drawing significant conclusions and further inferences.

This study established a viable methodology to manipulate UV levels in salt-marshes. Screened marsh vegetation (with or without UV being filtered out) presented morphological and physiological changes in the vegetation. Morphologically, *S. alterniflora* showed an increase in plant height as compared to uncovered-control-vegetation. Physiologically, *S. alterniflora* and *Salicornia* showed decreases in UV protective pigments as compared to unscreened-control-vegetation. However, the treatment where UV was screened out did not show differences from the plants exposed to UV. Therefore, the effect of UV-B screening is unclear at this point.

The absorption spectrum of pigments of plants exposed to no UV-B radiation was expected to yield clear reductions in the pigment concentrations in the UV range, as demonstrated by Figures 6 & 8. It should be noted that peaks in the 200-250nm range represent amino acids and soluble proteins, while the focus of this study is on the 280-315nm range where the plant contains a UV protective pigment(s) -- possibly flavonoids. An unexpected finding was a reduction of UV pigment in plants under the Aclar-control-covering and the Mylar filters. Clearly, this is a shading artifact of the screens. This also caused morphological changes in the plants, as was seen in Figure 3, where plants clearly etiolated over the course of the study.

Salicornia did not demonstrate a clear change in pigment concentration under screened or exposed conditions while *S. alterniflora* was affected after two weeks but later showed either a drop in pigments under the uncovered conditions or a refreshing (that is: a regeneration) of pigments while covered with Aclar or Mylar. This could be due to complications with the plastics. After approximately three weeks, both Mylar and Aclar plastics deteriorated from sun and wind exposure and were found to be ripped, torn, or otherwise no longer completely covering the plots. Also, it was necessary to remove all frames (supports to which the Mylar/Aclar films were attached) from the marsh to prevent extreme damage and/or total loss of the materials due to Hurricane Bertha. Thus, for 36-48 hours, the experiment was totally interrupted and all plants were subjected to ambient light intensity and UV levels. It may be stated with certainty that the data from the first two weeks of the study was not compromised by an interruption of UV filtering or light intensity screening. Thus, conclusions drawn for the first two weeks (Figures 4, 6, & 8: where *Salicornia* did appear to be slightly affected by screening and *S. alterniflora* showed definite effects from screening) should carry far more weight than conclusions regarding data from the end of the six week *in situ* study. This final data should be viewed with the exposure insight in mind, leading to the issue of further study: in order to draw true conclusions regarding the effects of UV radiation on marsh vegetation, further research is needed.

The oxidation of Cadmium Zinc Telluride (CZT) was studied using the chemical H_2O_2 as an oxidizing agent. Elemental and chemical information on a sample of CZT was obtained using X-ray photoelectron spectroscopy (XPS). The sample was first left untreated with H_2O_2 as a control and then etched with H_2O_2 for one, five and fifteen minute(s), respectively, to compare the oxidation of CZT at the conditions of different etching times. Mg K_α X-ray (E_p = 1253.6 eV) beams were used to bombard the CZT sample. Emitted photoelectrons from the CZT sample surfaces were collected and energy analyzed. Elemental and chemical information on the surfaces of the CZT crystals was obtained from the photoelectron spectra based on the peak positions of individual elements, and the information of surface composition was determined from the data of relative atomic concentrations extracted from the spectra. This experiment reveals that tellurium is very sensitive to the oxidation while cadmium and zinc were relatively inert to the etching agent. Carbon (the major contaminant) residing on sample surfaces can be reduced with increasing the H_2O_2 etching time. The impact of the tellurium oxidation to the performance of a CZT radiation detector will be discussed in the paper.

INTRODUCTION

Cadmium Zinc Telluride (CZT) is one of the advanced ternary semiconductor materials. Research of CZT was brought about to meet the need of room temperature radiation detection of energetic radiation, especially X-rays and gamma-rays. Unlike germanium detectors which require a liquid nitrogen temperature for proper operation, and silicon detectors which are not efficient for measuring energetic radiation, a detector made of CZT could be highly efficient, very compact, and operable at room temperature.[1] The research of CZT has also greatly benefited from the study of Cadmium Telluride (CdTe) semiconductors and the commercial success of CdTe devices. CdTe detectors can be operated at room temperature, have good stopping power for energetic radiation and produce reliable spectra, and be fairly rugged and convenient in field applications. However, the large leakage currents associated with CdTe detectors restrict them from most X-ray detection. The fact that CdTe crystals are difficult to grow, limits the manufacture of large scale detectors required for gamma-ray applications. Compared to CdTe, CZT retains similar stopping power for photons, but the reduced leakage currents make it suitable for X-ray applications. It is also less difficult to produce a large scale CZT detector for gamma-ray measurements. The first CZT based gamma-ray spectrometer was reported in 1992.[2]

The performance of a CZT radiation detector depends not only on the size and quality of the CZT crystal, but also heavily on the surface treatment of the crystal during fabrication of the detector. Tellurium precipitates and oxidation of crystal components, which determine the surface leakage currents and contact property of electrodes, have been found common on the surfaces of both CdTe and CZT crystals. Controlled surface oxidation, at ambient and/or elevated temperature, employing chemical etching and thermal annealing has been studied to reduce surface leakage currents and to create metal-oxide-semiconductor(MOS) structures.[3,4] However, no report has been found on the study of surface oxidation of CZT by employing hydrogen peroxide (H_2O_2), a conveniently available oxidation agent. In this study, a controlled oxidation process using H_2O_2 was developed to investigate surface modification with oxidation. X-ray photoelectron spectroscopy (XPS)[5] was employed to determined the chemical compositions on the CZT surfaces. The XPS results combined with the surface morphology measurements using atomic force microscopy (AFM) and dark current-voltage (I-V) measurements[6] can reveal detailed information about the dependency of device performance on the surface conditions of a crystal.

EXPERIMENTAL

A detector grade cadmium zinc telluride ($Cd_{0.9}Zn_{0.1}Te$ from eV Products) crystal wafer was used in

BEST COPY AVAILABLE

the study The wafer was first polished by a mechanical polisher using 0.05 micrometer alumina to smooth the outer surface. It was then washed in a methanol solution and chemically etched with 5% bromine in methanol for two minutes. It was then rinsed in methanol again and dried. Next, the CZT sample was treated in hydrogen peroxide solution (15% H_2O_2 + distilled water) in ambient air three different times. In the first test the sample was left untreated as a control sample, coded as CZT-H_2O_2-00. It was then etched in H_2O_2 for one minute, five minutes, and 15 minutes, and coded as CZT-H_2O_2-01, CZT-H_2O_2 and CZT-H_2O_2-15, respectively. After each treatment, the sample was placed into a UHV chamber for surface analysis using XPS. The XPS technique was used because it is a chemically sensitive and nondestructive method. XPS can determine which elements are within the near surface region of a sample and their chemical states.

The XPS measurements were conducted by employing the XSAM 800 spectrometer from KRATOS ANALYTICAL LTD. The major instruments involved in the experiments include an X-ray gun, an electron energy analyzer, electron detectors, and a sample manipulator. A laser and an electron gun were also used for the alignment of a sample. To prevent over-heating the X-ray gun during operation, a closed circulation cooling system using distilled water as the coolant was employed to cool the interior of the X-ray gun. The CZT sample was bombarded with Mg K_α X-rays emitted from the X-ray gun located at a 50° angle with respect to the electron energy analyzer. Photons from the X-ray gun were guided to hit the sample. Photoelectrons, emitted from the sample surface as a result of photoelectric excitation, carry the elemental and chemical information of the sample surface. The photoelectrons were collected and energy analyzed by the energy analyzer. The angular resolving study was conducted by rotating the sample each at 0°, 30°, and 45° angles with respect to the electron analyzer. Data made by the emitted photoelectrons were taken and stored using a SUN SPARC station. The spectra are plotted as the electron binding energy versus the number of electrons in a fixed, small energy interval. Each element is represented by a group of peaks corresponding to specific binding energies. The strongest peaks used in data analysis are: Carbon 1s at 284 eV, Oxygen 1s at 531 eV, Cadmium 3d at 405 eV, Tellurium 3d at 574 eV, and Zinc 2p at 1022 eV.

RESULTS/DISCUSSION

In analyzing the data, techniques such as smoothing, normalizing, fitting, and quantification, were used to obtain proper results from the spectra about the CZT sample. The different peaks in one spectrum of an element are due to electrons residing in different orbitals (levels), which have not lost energy while emerging from the sample. The raised background at binding energies higher than the peaks is formed by electrons that have lost energy. The deficiency of electrons caused the sample to be charged and the peaks shifted to the left. Figure 1 shows the spectra of the carbon for all four etching times. The peak with higher binding energy was from the carbon within the sample and the other peak is from the sample holder.

Figure 2 shows the spectra of oxygen from the CZT samples. The spectra identifies three peaks in the control sample and four peaks in the etched samples. The fourth peak with the smallest binding energy is the so-called satellite peak. The highest peak in the control sample corresponds to the smaller peak to the far left in the etched samples, which continually decreased as etching time increased. The intensity of the middle peak is increased significantly with the etching length, which is attributed to the formation of Te oxide on the sample surfaces. The third peak is mainly the species from the sample holder.

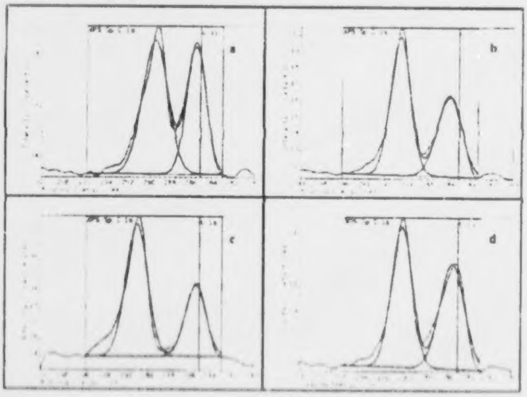

Figure 1. XPS Spectra of Carbon from CZT samples: a) without H_2O_2, b) one minute H_2O_2 etching, c) five minute H_2O_2 etching, and d) fifteen minute H_2O_2 etching.

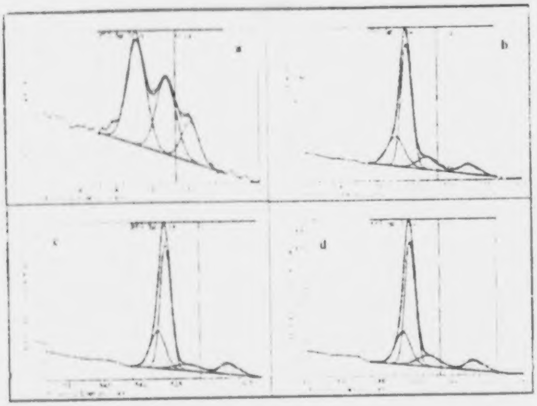

Figure 2. XPS Spectra of Oxygen from the CZT samples: a) without H_2O_2, b) one minute H_2O_2 etching, c) five minute H_2O_2 etching, and d) fifteen minute H_2O_2 etching.

Figure 3 shows the spectra of cadmium after normalization. Three peaks, assigned to the $3d_{5/2}$, $3d_{3/2}$ and the satellite peaks of cadmium, respectively, are present in the CZT sample. The spectra show that cadmium reacted very little to the oxidation because the cadmium peaks only slightly changed in height and width.

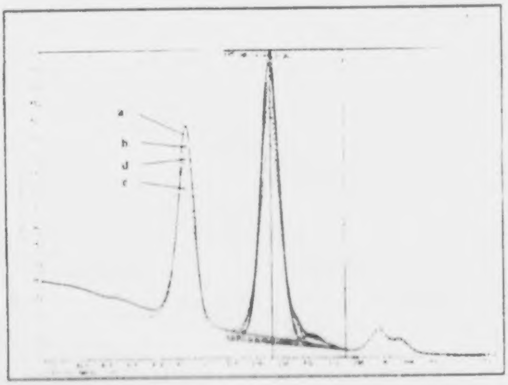

Figure 3. XPS Spectra of Cadmium from CZT samples: a) without H_2O_2, b) one minute H_2O_2 etching, c) five minute H_2O_2 etching, and d) fifteen minute H_2O_2 etching.

Figure 4 is the spectra of zinc. Similar to cadmium, the zinc peak changed only slightly in height, which is shown by the different heights of the backgrounds. This indicates that the zinc on the CZT was not very sensitive to the oxidation.

Figure 5 is the spectra of tellurium, where the two major peaks are $3d_{5/2}$ and $3d_{3/2}$, respectively, and the satellite peaks are to the further right of the spectra. Tellurium was reactive to the oxidation, evident by the shifts in the peaks. The intensity of the initial control peak decreased gradually with H_2O_2 etching length, while the oxidation peak to the right side of each control peak increased sequentially and reached a saturation stage after about five minute of etching.

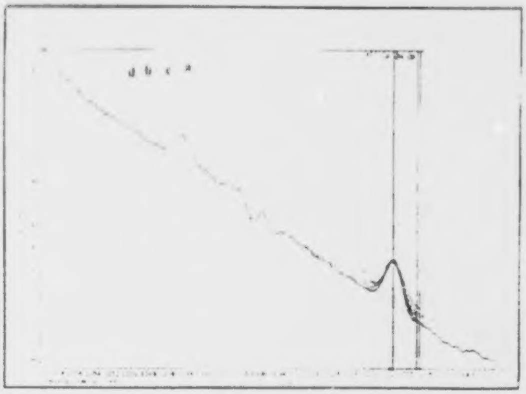

Figure 4. XPS Spectra of Zinc from CZT samples: a) without H_2O_2, b) one minute H_2O_2 etching, c) five minute H_2O_2 etching, and d) fifteen minute H_2O_2 etching.

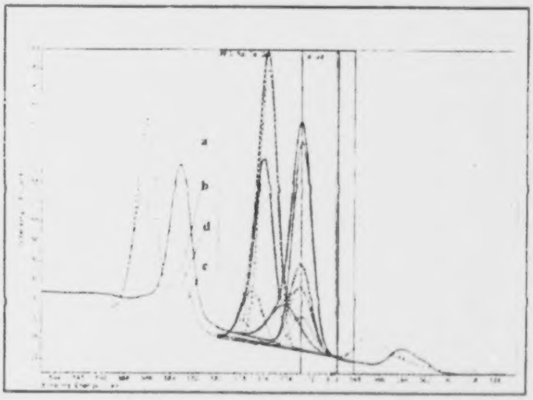

Figure 5. XPS Spectra of Tellurium from CZT samples: a) without H_2O_2, b) one minute H_2O_2 etching, c) five minute H_2O_2 etching, and d) fifteen minute H_2O_2 etching.

The graphs were smoothed where necessary and fitted on the same background, represented by the base line on each figure. Peaks were normalized for easy observation. The elements with contamination from the sample holder were carbon and oxygen. Satellite peaks are obvious in the spectra of cadmium, tellurium and oxygen because the primary peaks in these elements are strong and clean so that the satellite photon from the Mg x-ray source can be easily identified.

The relative atomic concentration of each element was created for each sample and its different rotations as shown in fig.6. The plots were calculated using the quantification data sets of the individual peaks in each element at the different etching lengths. For comparison, three oxygen species (normal surface contaminants, TeO_2 and the effect of the sample holder) and two tellurium species (CZT and TeO_2) were quantified and plotted along with zinc and carbon. The atomic concentration of each peak was normalized to the atomic concentration of the 3d peak of cadmium (not seen in the plot) which is unity. The major peak of each element is considerably larger than cadmium (except zinc), evident by their position on the chart which is above one. The abscissa is coded as AA-BB, where AA represents the minutes of H_2O_2 etching, and BB is the take off angle in degree.

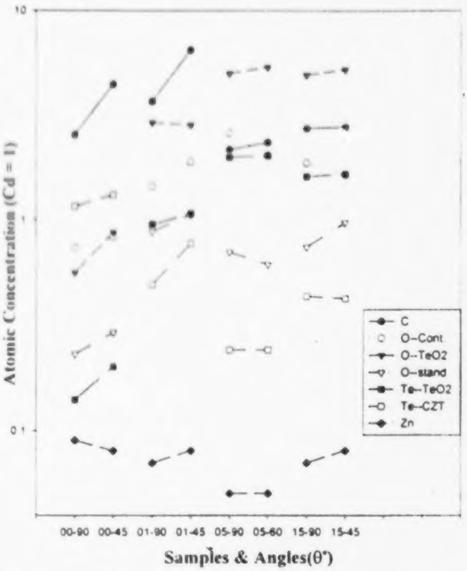

Figure 6. Atomic concentration of surface species on CZT.

Carbon contained primarily two peaks, one peak corresponded to the carbon atoms residing on the surface of the sample, and the other peak was the result of contaminants from the sample holder. The plot of relative atomic concentration shows how carbon was reduced with an increase of etching time. The carbon not etched in H_2O_2 had a slightly lower concentration than when etched for one minute, but generally the concentration decreased. There were three major species of oxygen. The first was the common contaminants, maybe CO_2 or CO. The second peak was assigned to TeO_2, which is small in the first data set of the sample without H_2O_2 etching for both take-off angles 90° and 45°. It first increases and then begins to decrease with increasing etching time. The third peak of oxygen is due to the holder. Cadmium was not sensitive to oxidation. Cadmium peaks were used for normalization because they were clean, strong (to reduce statistical errors), and had little change. Tellurium had two major species. The first species was from the CZT crystal, which steadily decreased as etching time increased. The second species was from the reaction with oxygen, which first increased and then began decreasing with increasing etching length, therefore, making a saturation. Zinc was not sensitive to the oxidation. It was also weak and maintained a small concentration (5-10% of Cadmium).

CONCLUSION

Carbon was residing on the surfaces of all the samples. Its atomic concentration decreased as H_2O_2 etching time increased, which means that H_2O_2 has the effect to remove the surface contaminants. Oxygen displayed three peaks in the untreated sample and four peaks in the treated samples. After a certain time of H_2O_2 etching, one oxygen peak became dominant and related to the surface, which hints that a new oxidation layer was formed on the surface assigned to the TeO_2 layer. Cadmium showed three peaks and Zinc showed one peak. The oxidation of CZT was increased while increasing the H_2O_2 etching time and reached saturation after about five minutes etching. The formed oxidation layer was attributed primarily to TeO_2 and a small amount of Cd oxide. No obvious Zn oxide was found. AFM and I-V measurements revealed that the H_2O_2 oxidation reduced the surface roughness and leakage current so that this treatment can improve the performance of the CZT detector.

The Effects of Precocene 2 on The Predatory Insect *Tenodera aridifolia sinensis* Saussure

Faculty Advisor:

Diane Melroy

Precocene 1 and 2 are naturally occurring secondary products found in the common bedding plant, *Ageratum houstonium*. They cause phytophagous and omnivorous insects to undergo precocious metamorphosis by degrading the corpora allata, thus stopping juvenile hormone synthesis.

This research looked at the effects of Precocene 2 on the praying mantis, *Tenodera aridifolia sinensis* Saussure, when given two different treatment regimens. One hundred fifty juvenile mantids were fed immature crickets treated with Precocene 2. An additional one hundred fifty juvenile mantids were treated topically with Precocene 2. All mantids were then allowed to develop. The mantids fed treated prey died, while those topically treated exhibited greatly lengthened instars. In contrast to published literature, no precocious metamorphosis was observed.

INTRODUCTION

William Bowers and his colleagues found that secondary products, extracted from the common plant *Ageratum houstonium*, (precocene 1 and 2) had antiallatotropic properties for many species of insects. They showed that precocenes degraded the corpora allata, site of juvenile hormone synthesis (Bowers & Pardo, 1977). Juvenile hormone is critical in several physiological functions of the insect, including control of whether the insect remains a juvenile, or metamorphoses to the adult form (Romoser and Stoffolano, 1994). Ecdysone, a hormone secreted by the prothoracic gland, works with juvenile hormone. A spike of ecdysone signals the end of each instar by stimulating molting. If juvenile hormone was present, the insect remained in the immature state (Riddiford and Truman, 1978). In past research, many types of hemimetabolous insects, treated with Precocene 2 showed adult characteristics one intercalary instar after treatment, due to the destruction of the corpora allata and loss of circulating juvenile hormone. These insects included the milkweed bug, cockroach, planthopper, leafhopper, cricket, and locust (Bowers, et al.; 1976, Ayoade, et al.; 1996, Bradley & Haynes, 1991, Eid, et al.; 1988, Bowers & Pardo, 1977). Adult characteristics include the formation of wings, adult color patterning, and external genitalia (Wigglesworth 1972, Romoser & Stoffolano, 1994). The precocious females produced after treatment with precocene 2 were sterile as the corpora allata also plays a role in vitellogenesis and therefore, formation of eggs (Bowers & Pardo, 1977). This raises the possibility of using precocene 2 as a biological control agent, but at present time the cost appears prohibitive.

The purpose of this study was to test the effects of precocene 2 on the praying mantis. Most of the previous research had been done with phytophagous insects and the question was raised as to whether the predatory mantis would be affected in the same way as other insects, and if there would be any effect on them from eating treated prey. The usefulness of precocene 2 as a biological control agent would be compromised if its effects were magnified in the food chain.

METHODS AND MATERIALS

General:

The precocene 2 (6,7-dimethoxy-2,2-dimethylchromene) used for the experiments was obtained from Aldrich Chemical Corp. Precocene 2 was dissolved in acetone under nitrogen and placed in a freezer until use. To control for the use of acetone, separate untreated and acetone-only treated controls were tested.

Animals:

The mantids used in the experiments were captive bred from wild mantids caught from July-September 1996 and individually housed in 180 cm^2 cages in a greenhouse. Ootheca were obtained from mated females and kept at room temperature for one week. The oothecae were transferred to a 5°C refrigerator for one week, a -20°C freezer for one week, then back to the refrigerator. Approximately one month prior to use, the oothecae were removed from the refrigerator and held at room temperature. One week prior to hatching the oothecae were placed in an incubator at 30°C. Hatchlings were kept together in 85 liter aquaria and supplied with *Drosophila* and spring water *ad lib*. Temperatures were kept at 26±4 C with a 16L:8D photoperiod. One week after hatching, the animals were moved into individual 4x10 cm *Drosophila* culture vials (Carolina Biological Supply Company) and fed *Drosophila*, immature crickets, and *Tenebrionidae* larvae. At fourth instar, surviving mantids were transferred to 500 mL clear plastic cups with lids. At sixth instar the mantids were moved into 1 liter clear glass jars. All animals were fed and watered daily.

The crickets were purchased newborn from Catawba Cricket Hatchery, Charlotte, NC. and housed in a 130 liter aquarium with Gerber Stage 2 oatmeal with bananas and water *ad lib*.

Feed Through Experiment: One hundred eighty second instar mantids were randomly selected and placed in groups of thirty, with daily rotation of cages. The mantids were offered immature crickets (ten per mantid), which had been treated with precocene 2 dissolved in acetone and allowed to molt once to remove any residue of acetone or precocene 2 (Table 1). For treatment, the crickets were placed in paper lined petri dishes. One microliter of precocene 2 in acetone was applied to the dorsal surface of each cricket. After 24 hours the crickets were placed in clean cages with fresh water and baby food. The mantids used as untreated controls were offered immature crickets that had no exposure to precocene 2 or acetone.

Table 1. Treatment levels for the feed through experiment

Group #	# in Group	Dosage per Cricket *	Total Dose per Mantid
1	30	0 ug/uL	0 ug precocene 2
2	30	1 uL acetone	0 ug precocene 2
3	30	1uL @ 1 ug/uL	10 ug precocene 2
4	30	1 uL @ 2 ug/uL	20 ug precocene 2
5	30	1 uL @ 3 ug/uL	30 ug precocene 2
6	30	1 uL @ 4 ug/uL	40 ug precocene 2

* The dosage per cricket indicates the amount of precocene 2 dissolved in acetone per uL applied to each cricket.

Topical Experiment: One hundred fifty newly molted second instar mantids were randomly selected and placed into groups of 30, with daily rotation of cages. The mantids were treated with precocene 2 dissolved in acetone and applied with glass micropipets to the ventral surface of the abdomen (Table 2).

Table 2. Dosage levels for topical application of precocene 2 in acetone.

Group	# in Group	Dosage Level
A	30	0 ug/uL
B	30	1 uL acetone
C	30	10 ug/uL precocene 2 in acetone
D	30	20 ug/uL precocene 2 in acetone
E	30	30 ug/uL precocene 2 in acetone
F	30	40 ug/uL precocene 2 in acetone

RESULTS

Feed Through Experiment:

In the feed through experiment, none of the mantids in the treated groups survived to reach third instar. After ingesting part of one treated cricket, the mantids refused all other food. This occurred even in the acetone treated group. Within five days of treatment, all of the mantids except for untreated controls died. Mortality for the untreated controls (data not shown) was within 0.5% of the mortality for the topically treated mantids (Figure 1).

Topical Experiment:

Mortality in the topically treated experiment was considerable throughout each treatment group. Most of the mortality seen was at or just after each molt. The untreated controls showed less overall mortality, with 60% surviving 5th instar (Figure 1). From the data, it appears that the acetone was responsible for part of the mortality in treated groups but that precocene further increased the mortality rate, especially at higher doses. While 46.7% of the acetone treated controls survived through 5th instar, only 33.3% of the 20 ug/uL group survived, and none of the 30 ug/uL survived through 5th instar (Figure 1). Mortality for the group treated with 40ug/uL precocene was 100% prior to any mantid reaching 3rd instar. Most died with in 48 hours of treatment, with the longest surviving 8 days (data not shown).

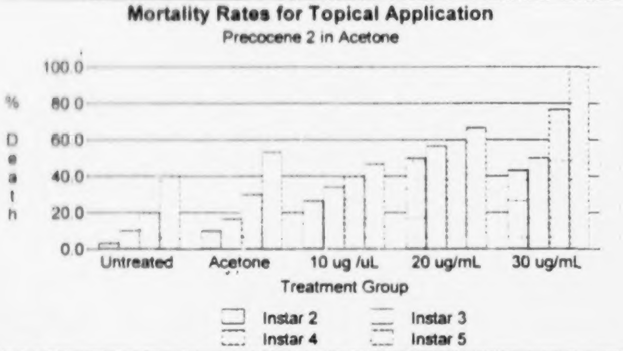

Figure 1. Mortality rates for each instar after topical application of precocene 2 in acetone. Percent of mantids not surviving molt into next instar.

The average length of each instar was affected by treatment with precocene 2 (Figure 2). In the untreated controls, instar length averaged 10.0 days for instar 2 to 30.0 days for instar 5. Acetone treatment increased the instar lengths to 11.9 and 31.8 days respectively. This increase was shown to be statistically significant when repeated measures ANOVA was performed; P values < 0.0001. The remaining statistical analysis compared the acetone treated to the other treatment groups. The 10 ug/uL group showed less lengthening of the instar when compared to the acetone treated mantids, with the 20 ug/uL and 30 ug/uL groups showing a statistically significant lengthening of the respective instars. P-values for the data ranged from <0.005 to <0.0001.

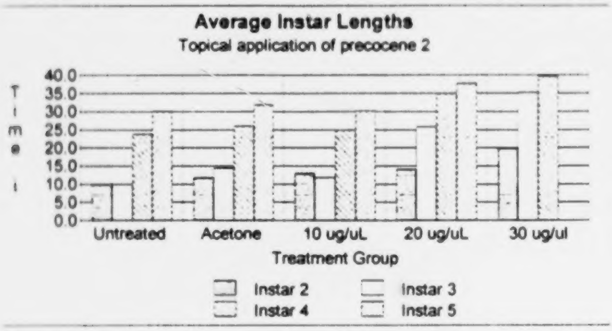

Figure 2. Average instar lengths after topical application of precocene 2 in acetone.

Two animals from each surviving treatment group were dissected at 15 days into 6th instar to compare the sizes of their corpora allata. Length and width measurements were within 0.01mm, regardless of treatment group. Gonad development had not occurred, so fertility was not assessed.

DISCUSSION

The feed through experiment showed that eating treated crickets caused the mantids to be unable or unwilling to feed, thus starving themselves to death. Since the crickets had undergone one molt prior to being used to feed the mantids, there should not have been any acetone or precocene 2 on the exoskeleton. As this occurred even in the acetone controls, it appears that acetone alone has a strong effect on the feeding response in mantids. Acetone may damage or destroy the feeding apparatus, or interfere with regulation of feeding. No effect attributable to precocene was observed.

The mortality in the topically treated mantids shows that precocene 2 is toxic at higher levels. There appears to be an increase in mortality at instar 5 in the untreated and treated controls that is not seen in the 10ug/uL or 20ug/uL groups. The significance of this is not known, but needs to be looked at more closely. There was no precocious metamorphosis observed in any of the treatment groups. Predatory insects appear to contradict the findings of Bowers et al (1976), Unnithan et al (1977), Ayoade et al (1996), and others, which showed that treatment with precocene 2 induced precocious metamorphosis in phytophagous and omnivorous insects after one intervening instar. Lengthening of a single instar was observed by these researchers, but the instar extensions being carried over into each following instar appears to be a new finding.

The known effect of precocene 2 is to destroy the corpora allata thereby eliminating the animal's ability to synthesize juvenile hormone. In the absence of juvenile hormone the animal molts to the adult form after one intercalary instar (Bowers et al, 1976) and that the instar is lengthened. In these experiments, however, all instars were significantly lengthened and no precocious adults were formed. There may be several explanations for this. Mantids may have biochemical pathways not found in the insects tested to date, allowing precocene 2 to be metabolized. It is also possible that in mantids precocene 2 interacts with the corpora cardiaca, which releases prothoracicotropic hormone and stimulates the prothoracic gland, where ecdysone is produced, or with the ecdysone itself. An altered ecdysone metabolism might be expected to result in lengthened instars. Additional experiments are being designed and conducted to help answer these questions.

ACKNOWLEDGMENTS

The author would like to thank the following:

The entire Biology department at UNCA for all of their help and support.

Ms. Lorrie Gunter, for her help in maintaining the breeding colony, and for always being there.

Special thanks go to:

Dr. Diane Melroy, for without her faith in me, this research would never have been possible.

M. Richard Hawes, for giving me the boost I needed five years ago.

My husband, Steve, for building all of the cages and allowing me to convert the spare bathroom to a research lab.

Interspecific Interference and Resource Partitioning Among Males of Three Dragonfly Species (Odonata: Libellulidae)

By Michael Wolyniak
Department of Biology, Colgate University, 13 Oak Drive, Hamilton, New York, 13346
Faculty Advisor: Dr. Vicky McMillan

This project examined interspecific interference and resource partitioning among three dragonfly species, *Plathemis lydia*, *Libellula luctuosa*, and *Libellula pulchella*, at common breeding sites in the southern Madison County region of New York. Census data and observations of reproductive behavior indicated that these species overlapped both spatially and temporally, utilizing the same shallow water areas for male patrolling, perching, pair formation, mating, and oviposition. Interspecific interactions accounted for up to 40% of all aggressive interactions between males, depending on the species. However, males showed interspecific differences in both perching and flying behavior. Under natural conditions, *P. lydia* males preferred lower perches than those used by male *L. luctuosa* and *L. pulchella*, moreover, *P. lydia* was the only species that utilized ground perches. Studies with artificial perch sites constructed from dowels showed that *P. lydia* preferred sites less than 40 cm. high, *L. luctuosa*, sites 40-50 cm. high, and *L. pulchella*, sites 90-100 cm. high. With rare exception, dowels with horizontal perch sites at a height of 60 cm. were utilized only by *L. luctuosa*. Observations of flying behavior under natural conditions showed that *P. lydia* was typically active at lower heights (0-0.5 m) when compared to *L. luctuosa* (0.5-1.0 m) and *L. pulchella* (0.5m+). These differences in perching and flying behavior may reflect ways in which resources (perch sites, air space, etc.) are partitioned among these closely-related species, permitting simultaneous use of the same breeding areas and, perhaps, reducing the frequency of interspecific interactions.

BACKGROUND

The simultaneous presence of multiple species of odonates in a particular breeding area has served as the basis for a number of experiments exploring interactions between such species in attempts at cohabitation (Hilton 1983, Michiels 1987). However, little work has been done in the examination of competition and resource partitioning between the overlapping species of *Plathemis lydia*, *Libellula luctuosa*, and *Libellula pulchella*. These species have been intensively studied with respect to territoriality and reproduction (Moore 1989, Koenig 1987, Pezalla 1979). However, a complete understanding of their behaviors cannot be obtained without considering the interactions and encounters which are inevitable for species such as these with similar male territorial requirements of a sunny exposure and sites suitable for perching and female oviposition (Pezalla 1979). It is possible that species such as these are the products of divergence from a common ancestor, resulting in the development of individual niches in the ecosystem in which each species may survive and adequately coexist with each other. The aim of this study is to provide information contributing to a greater understanding of this evolutionary process through observations of the degree of coexistence among these three dragonfly species. In this study, the natural behaviors of *P. lydia*, *L. luctuosa*, and *L. pulchella* were observed both as individual species and as part of a common breeding site in an effort to explore the evolutionary conditions which have developed among these species.

MATERIALS AND METHODS

The natural behaviors of *P. lydia*, *L. luctuosa*, and *L. pulchella* were observed over a period from 10 June to 29 July 1996 at two artificial ponds 4 km east of Hamilton, Madison County, New York. The small pond was roughly 8 by 5 meters and characterized by the presence of grasses, sedges and *Salix* along the shorelines and *Typha latifolia* and *Myriophyllum* in open water areas. The large pond, located 66 meters from the small pond, was roughly 16 by 14 meters, generally devoid of shoreline vegetation, and contained patches of *Myriophyllum* in open water areas. Numbered stakes were placed along the shoreline every 3 m in order to establish a method to identify locations of territories and perching sites. Individuals of each species were captured at the conclusion of each observation day and marked with a unique pattern of enamel paint on the thorax, abdomen, and/or wings. Census observations were also taken on a daily basis to establish relative seasonal densities. In many cases, multiple sets of data were taken from individual dragonflies as they returned to their territories throughout the season. A number of different behavioral characteristics were observed:

Perch distance from shore: Individuals of each species, whether marked or unmarked, were observed for 15 minute periods in their respective territories. The distance from the shoreline of the pond where the dragonfly perched was recorded each time the specimen exhibited perching behavior during the 15 min interval. For the males examined in this study, 1 to 5 observation periods were taken on each individual.

Perch height under natural conditions: The relative height of perching above the level of the shoreline was also observed among individuals for 15 minute intervals in their respective territories. Each time the individual perched, its height above the shoreline was recorded. A height of zero was recorded if the specimen perched on the ground. For the males examined in this study, 1 to 5 observation periods were taken on each individual.

Perch height under artificial conditions: An artificial perching site was constructed from dowels to simulate ideal perching conditions for the dragonflies under study (Pezalla 1979). Two one-meter dowels were connected in a perpendicular fashion at a point 60 centimeters from the end of one of the dowels, creating a cross shape. These dowels were marked with lines of various colors at 10 centimeter intervals to allow for accurate observations of perching height. The dowels were placed in a clear area of the shoreline where there would be little competition from local vegetation for perching sites. Individuals were observed for 15 minute intervals and the height of each perch on the artificial site was recorded. Use of the horizontal perch site created by the cross was recorded separately as a distinct height. For the males examined in this study, 1 to 3 observation periods were taken on each individual.

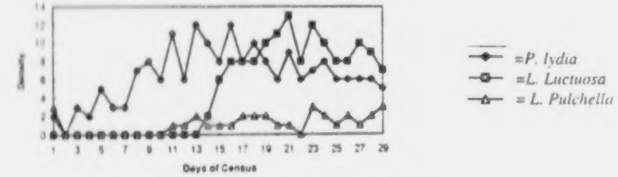
Flying height: Flying height was observed using a beeper adjusted to beep at 3-second intervals. At each beep, its was recorded whether the specimen under observation was flying at a height below 0.5 meters, between 0.5 and 1.0 meters, or above 1.0 meter. This process continued throughout the 5-minute interval of observation for each individual. Dowels with markings at each 10 centimeter interval similar to the ones used in the perching height study were used to accurately observe the relative height of each flight. For the males examined in this study, 1 to 3 observation periods were taken on each individual.

Aggressive behavior: Intraspecific versus Interspecific interactions: Chasing behavior was observed for individuals over 15 minute periods. The number of aggressive interactions, or incidents which resulted in a territorial male defending its territory through the chasing of another male, were recorded. To illustrate the influence of interspecific aggression on effective coexistence, interspecific interactions were recorded separately from intraspecific interactions during each period. For the males examined in this study, 1 to 3 observation periods were taken on each individual.

Statistical Analysis: All results were analyzed through ANOVA and Tukey-Kramer multiple comparison tests. In the case of the flying height and aggressive interaction data, an arcsine transformation was performed on the data to correct for the heterogeneity of variance.

RESULTS

Seasonal and Daily Densities: The daily densities of each species at the large pond are shown in Figure 1:



While *P. lydia* were present in relative abundance throughout the observation season, *L. luctuosa* did not emerge in great abundance until the week of 24 June, and *L. pulchella* was only found in limited quantities throughout the season (see Figure 1). *L. pulchella* tended to remain at their breeding sites for an entire observation day but would usually not return after capture and marking. These observations agree with Pezalla's (1979) and Hilton's (1983) earlier findings. In contrast, *P. lydia* and *L. luctuosa* showed high degrees of site fidelity, returning to the same territorial site for weeks after capture and marking. However, the high population densities of these two species resulted in the ability of males to adequately guard territories for only a few hours each day, observations which concur with the work of Koeing (1990) and Moore (1987).

TABLE 1: Results of the perching and flying height studies:

Species	Perch distance from shore	Perch heights-Natural Cond.	Perch heights-Artificial Cond.	Flying Height
P. lydia	0.57 m	3.5 cm	35.0 cm	20.0 cm
L. luctuosa	3.14 m	31.5 cm	57.7 cm	36.0 cm
L. pulchella	0.67 m	64 cm	94.9 cm	37.0 cm

Perch distance from shore: *L. luctuosa* (N=24) perched at a significantly different distance from the shoreline than either *P. Lydia* (N=16) or *L. Pulchella* (N=13) (F=167.47, P<.0001). No significant difference was noted between *P. lydia* and *L. pulchella* (See Table 1). This significant difference between *L. luctuosa*'s perching habits and those of the other two species reflects the tendencies of *L. luctuosa* to perch in the vegetation surrounding the pond as opposed to sites closer to the actual shoreline.

Perch heights under natural conditions: A significant difference (F=140.44, P<.0001) was observed between all three species (*P. lydia:* N=16, *L. luctuosa:*N=24, *L. pulchella:*N=13) (See Table 1). These results reflect the high frequency of ground perching for *P. lydia* as opposed to the tendencies of the other two species to seek elevated perch sites.

Perch heights under artificial conditions: As with the natural conditions, significant differences (F=918.86, P<.0001) were observed for all three species in terms of perching on the artificial dowel perch site (*P. lydia:* N=10, *L. luctuosa:*N=10, *L. pulchella:* N=17) (See Table 1). The horizontal perch site at 60 cm above the shoreline was utilized almost exclusively by *L. luctuosa*, although the other two species did make rare appearances at this site.

Flying height: *P. lydia* (N=15) was observed to have a significantly different flying height from the other two species represented in this study (F=80.38, P<.0001) (*L. Luctuosa:*N=15, *L. pulchella:*N=8). No significant difference was noted between *L. luctuosa* and *L. pulchella* (See Table 1). However, *L. pulchella* was also observed to exhibit a wide range of flying heights and was the only one of the three species observed to regularly fly over the pond at heights exceeding 1.0 meters.

TABLE 2: Results of the interspecific versus intraspecific interactions study.

Species	% aggression with *P. lydia*	% aggression with *L. luctuosa*	% aggression with *L. pulchella*
P. lydia	60	37	3
L. luctuosa	32	66	2

Aggressive behavior: Intraspecific versus Interspecific interactions: For *P. lydia*(N=14), a significantly greater number of its interactions were intraspecific in nature rather than interspecific (F=197.78, P<.0001). The same was true for *L. luctuosa* (N=14) (F=479.76, P<.0001) (See Table 2). *L. pulchella* were not abundant enough for a study of aggressive behavior by this species.

DISCUSSION

This study revealed interspecific differences in perching and flying behavior which may help minimize the degree of interaction among *P. Lydia, L. luctuosa*, and *L. pulchella* at common breeding sites. First, the tendency of *L. luctuosa* to perch in the vegetation surrounding the pond at a distance of 3 meters or greater from the shoreline, as opposed to the shoreline itself, allows this species to perch relatively free of territorial interference from either *P. lydia* or *L. pulchella*. Such unique perch sites contribute to the development of interspecific territories similar to those noted by Michiels and Dhondt (1987) for *Sympetrum* species. Since *L. luctuosa* does not directly compete with other species for perch sites close to the shoreline, multiple species may share a common territory with a relatively small degree of interspecific interference (Hilton 1983).

BEST COPY AVAILABLE

While *P. lydia* normally perched on the ground or on rocks only a few centimeters from the ground. *L. luctuosa* perched at an intermediate height on vegetation, while *L. pulchella* used the same vegetation at a higher height. These observations suggest behavioral partitoning of perch sites among these three species, thus reducing the degree of interspecific interaction, conflict, and wasted energy.

L. Luctuosa used the horizontal portion of the artificial perch site at a greater frequency than the other two species. However, it is unclear if this reflects *L. luctuosa*'s preference for a perch site of intermediate height or for an elevated horizontal site. Future studies could examine this problem through the use of horizontal perches at varying heights to test the degree of usage by *L. luctuosa* as opposed to other species.

Observations of flying height revealed a lower average height for *P. lydia* than for the other two species, which were relatively similar in this respect. However, these data do not reveal the versatility of flight which characterized *L. pulchella*. Such behavior suggests that these three species possess unique airspace niches similar to those found in the perching studies, with *P. lydia* preferring heights relatively close to the ground, *L. luctuosa* flying at an intermediate height, and *L. pulchella* utilizing the highest airspace. While some degree of overlap between these airspaces is present, such an arrangement reinforces an energy-efficient system which emphasizes a minimum of interspecific conflicts.

The observations of this study showed that even at midday, at peak population densities, intraspecific aggression among *P. Lydia* and *L. Luctuosa* was far more common than interspecific aggression, a conclusion which agrees with studies performed by Koenig and (1990). When interspecific conflict took place, it usually occurred when two dragonflies were flying at similar heights above the water. While interspecific aggression occasionally disrupted mating attempts or oviposition periods of females, such instances were rare, accounting for less than 10 percent of all aborted matings and were almost never the result of an interspecific mating attempt.

Overall, distinct perching and flying behaviors exist between *P. Lydia*, *L. luctuosa*, and *L. pulchella* which may facilitate simultaneous co-habitation. This common utilization of a breeding site allows for a minimum of interspecific interaction, thereby allowing for energy-efficient resource partitioning and coexistence among these species.

ACKNOWLEDGEMENTS

I thank Dr. Vicky McMillan for her sponsorship and guidance during this study. Without her inspiration and support, this study would not have been possible. Also, I would also like to thank Dr. Robert Arnold for his invaluable assistance in the statistical analysis of the data. I am also grateful to the Colgate University divisions of Natural Science and Mathematics and University Studies for generously providing the funding necessary for this study.

Habitat Selection by American Kestrels (Falco sparverius) Wintering in Northwestern Ohio

J. Eric Juterbock

The benefits gained by kestrels which overwinter in Ohio, rather than migrating further south, is a poorly studied aspect of their behavior. Examining these benefits requires a thorough understanding of where they are found in their winter range and, ultimately, why they are found there. Intersexual competition is known to occur, displacing males from the more desirable habitat. This may lead to increased predation of males by accipiters.

Cultivated crop land predominated in the study area, and more kestrels were found there as a result; they were not, however, disproportionately represented in cultivated habitat. Female kestrels were significantly more abundant than males in the study area. This supports the hypothesis that females are displacing males to less productive, or less safe, habitats.

INTRODUCTION

Although the habitat preferences of kestrels have been extensively studied, a continuation is warranted. Intensive agriculture continues to influence suitable hunting habitat since widespread pesticide use is still the preferred method of farming. The kestrel is dependent on invertebrate prey (annelids and arthropods) and meadow voles (Microtus spp.) which are adversely affected by pesticides. Many raptorial birds are considered biological indicators because of their position in the foodchain. Kestrels have, thus far, adapted readily to human activities. They are frequently spotted hunting from utility lines across the continent.

Several studies have indicated an intersexual difference in winter habitat use. Koplin (1973) reported significant segregation in northern California. Males predominated in wooded, agricultural habitats and females congregated in pastures or open fields. Mills (1976), Stinson et al. (1981), Smallwood (1981), Bohall-Wood and Collopy (1986) and Smallwood (1988) all reported similar results, but Sferra (1984) and Toland (1987) reported no such segregation. In addition, although unbalanced sex ratios have been reported in numerous studies across North America, there has been no consistent preponderance of one sex in any given geographic range. Roest (1957) and Enderson (1960) reported more males in the northern sites and Smallwood (1981) reported significantly fewer males at southern sites. However, Koplin (1973) reported fewer males in the north and Stinson et al. (1981) reported more males in the south and in Texas and Arizona. Mills (1976) reported a near one-to-one sex ratio.

The intentions of this study were: 1) to supplement available literature on sex ratios and habitat choice; 2) to monitor established populations; and 3) to examine factors that affect these. Although previous population estimates were unavailable for this study area, Bildstein (1978) provided a previous estimate in south central Ohio for comparison.

STUDY AREA AND METHODS

Road surveys were conducted late November through late February, the winter of 1996-1997, in Hardin County, Ohio. Hardin County has a land area of 747 km^2 which were transected on north-south secondary roads, separated by 1.6 to 3.2 kilometers. Roads traveled were chosen according to orientation and to cover maximum area while

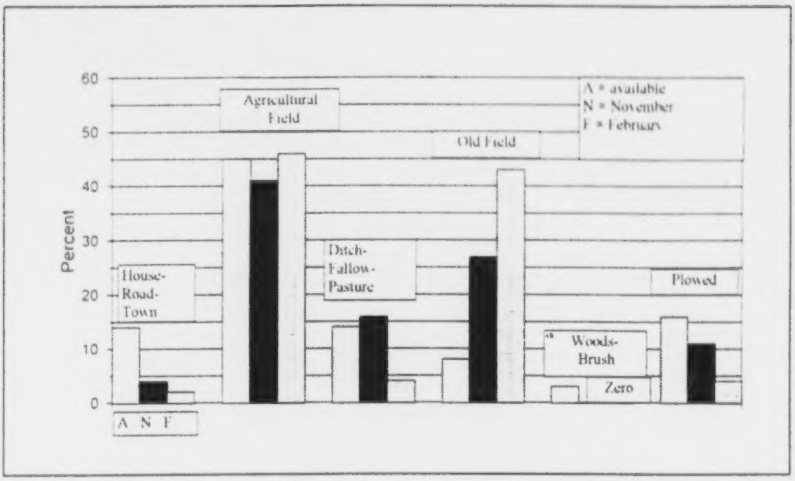

Figure 1 Habitat Available and Habitat Hunted in November and February

minimizing the possibility of spotting the same kestrel twice. Speeds of 27-56 kph were traveled while scanning a distance of approximately 100 m on both sides of the road. Censuses were conducted in precipitation free periods without strong winds since either could affect kestrel activity (Gawlik et al., 1990). Surveys began no earlier than 0900 hours and were concluded before 1630 hours EST. Kestrels display no significant afternoon lull of activity (Bunn et al., 1995), therefore time-of-day correction factors were not needed. Six different types of habitat were distinguished: lawn/town/road; agricultural field; ditch/fallow/pasture/hay; old field; plowed; and, brush/woods. Habitat was sampled on both sides of the road every 1.6 km. When a kestrel was sighted, it was almost always hunting from utility lines. Since both sides of the road were potential hunting grounds, each was counted as that individual's hunting preference. The kestrel's immediate behavior and sex were also noted using 7 X 35 binoculars and plumage characteristics.

To determine if a significant difference in habitat utilization with respect to habitat availability existed, chi square tests for independence were applied on February and November's data independently. To determine if a difference in habitat use between sexes existed, the data were analyzed using chi square tests of independence. Also chi-squared tests of independence were applied to the data collected in November and February with respect to sex ratios to determine if there was a significant difference between early and late winter proportions.

RESULTS AND DISCUSSION

Significant differences between the habitat utilized and the habitat available in both November and February data were obvious (x^2 = 26.6, d.f. = 5; x^2 = 55.0, d.f. = 5 -- respectively). The results were over twice the critical value for November and five times the critical value for February. When proportions were examined it was apparent that kestrels preferred old fields to any other habitat (Fig. 1). Old fields only cover 8 percent of Hardin County, whereas 27 percent in November and 43 percent in February, of the kestrels, were hunting that habitat. They hunted agricultural field proportionately to availability. This demonstrates their ready adaptability. However, no significant difference in intersexual preference were found(x^2 = 2.64, d.f. = 4) although wooded habitat was not included in my statistical analysis because no kestrels were sighted in that habitat. The proportion of wooded habitat was only 4 percent so it cannot be determined if either sex was avoiding that portion.

The analysis of the sex ratio revealed a significant difference in proportion across the winter season ($x^2 = 5.0$, d.f. = 1). Three times the number of females with respect to males were sighted in November, but by February the male population was almost twice that of the female (Table 1). The male population was more stable through the winter (n = 10 for November; n = 13 for February).

Table 1. Sex Ratios of Kestrels Over the Winter Season[a]

	Males	Females	n
November	29	71	35
February	62	38	21

a) Values given as percent population.

Kestrels are the smallest raptor in North America and are difficult to detect despite their use of utility lines. To determine the relative population of my study area, I adopted the correction factor of 3.0 proposed by Craighead and Craighead (1956), and utilized by Bildstein (1978), to accurately estimate the population size. The winter population was 0.14 kestrels per squared kilometer in November and 0.09 kestrels per squared kilometer in February. This deviated from the report of Bildstein of 0.32 kestrels per squared kilometer in 1978. A possible explanation for this deviation is a difference in habitat quality. A local Audubon society has conducted annual Christmas counts in the study area described by Bildstein. Apparently, birds localize in this area. Balgooyen (1973) reports that small birds are an important component of the kestrel diet during the winter when arthropods are absent. Since small birds localize in this area it could explain the high kestrel density reported by Bildstein, the kestrels are utilizing a rich food source. Several other explanations could also explain the difference. The ability to spot or not spot kestrels in dense cover being one of them. Another, less likely and requiring further research, is that since 1978 kestrels are not doing as well.

A couple of explanations have been offered to explain the sex ratio phenomenon. Many raptors exhibit pronounced sexual dimorphism (Koplin, 1973), while kestrels are sexually dimorphic they are much less so. Dividing the habitat may serve to reduce competitive pressure for limited, winter resources. Another, more recent explanation is differential migration. Smallwood (1988) reported that females migrate southward almost a month before males. This could explain the skewed sex ratio toward females in November and markedly reduced by February discovered in the Ohio study area.

Excessive mortality might also have decimated the female population, or possibly the ratio is merely a consequence of the local availability of habitat (Stinson et al., 1981; Mills, 1976). It has been quantified that females are generally found hunting in open habitat, whereas males are found in shrubby, wooded habitat, whether they prefer their chosen habitat or if it is a consequence of differential migration is still an issue of contention. My study area was composed of 96 percent open area. In many birds, the first individual occupying a piece of habitat is usually successful in defending that habitat and in kestrels, defending ownership almost always results in victory, (Smallwood, 1988) regardless of sex. This observation conflicts with Cade (1955)and Roest (1957), they reported that females were more aggressive as nestmates and continued to dominate males as adults.

If excessive mortality is the reason for the female population decreasing, then the benefits of not migrating must be great. Winters in Ohio can be fierce and sub-zero temperatures are common. This creates intense pressure for overwintering birds, but the pressure and costs of migrating must be greater. The mating season of the kestrel is dependent upon female readiness and fitness. She cannot produce viable eggs without suitable health and weight. In the Eurasian kestrel, the counterpart to the American kestrel, early laying females had 49 percent more body reserves than late laying females (Meijer, 1989). The loss of body reserves during migration is understood. Many of these birds travel thousands of miles in a short period of time. Possibly a female can conserve those reserves by "gambling" that a particular winter will be mild. The benefits, if the reproductive triggers of the Eurasian Kestrel are the same, include larger, earlier nests with the possibility of a second brood (Toland, 1985).

Superior prey resources are not the only desired characteristics of preferred habitats. The kestrel is the smallest North American falcon, smaller than the accipitrine (wood inhabitants) hawks. Since most raptors consider anything smaller than themselves prey, this leaves kestrels vulnerable to interspecific predation. The remains of kestrels have been found in the stomach of both Cooper's Hawks and the Sharp-shinned Hawk (Roest, 1957). More studies are needed before a conclusive explanation can be offered and further investigation into the effect of predator/prey dynamics is needed. In my study, Cooper's hawks were uncommon. That forests, their preferred habitat, only covered 4 percent of Hardin County is a probable explanation. In southern Florida the accipiters are basically nonexistent and in southwestern United States, likewise. Possibly geographical differences in habitat segregation exist as a result of predation. Again, further study is needed.

SUMMARY

Selective habitat use, with respect to availability, was observed in my study area. Kestrels significantly preferred old field habitat, although it only covered 8 percent of the area. No significant intersexual preferences were found, possibly because accipiters are uncommon in this portion of their range. Almost three times as many females were sighted in November and almost twice as many males were sighted in February. Independent migration or high mortality are the probable factors affecting this sex ratio. There was a remarkable difference in the population size with respect to a previous estimate because of differences in habitat resources.

The Role of Calcium in Wound-Induced Cell Proliferation

Quoc-Huong Tran

Department of Pharmacology
University of Minnesota

Minneapolis, MN 55455

Faculty Advisor:

Paul J. Sammak, Ph.D.

Cell proliferation is important in such processes as normal development, cancer and wound healing. In particular, the growth of endothelial cells to form new blood vessels regulates the rate of wound healing and tumor growth. Exploring the mechanisms involved in the control of cell proliferation aids in finding treatments for diseases such as cancer and for prompting wound healing. The cell model used by our laboratory involves confluent monolayers of calf pulmonary artery endothelial cells grown on glass coverslips. Previously, we found that mechanical wounding induces a transient rise in intracellular calcium which in turn sets the rate of cell motility. This project investigates how a one-time elevation in intracellular calcium concentration ($[Ca^{2+}]_i$) affects proliferation.

Mechanical wounding in HBSS buffer resulted in a control cell proliferation rate of 75%. To test the role of $[Ca^{2+}]_i$ in cell proliferation, we blocked $[Ca^{2+}]_i$ elevation with gadolinium (Gd^{3+}), a Ca^{2+} channel blocker and EGTA, a Ca^{2+} chelator. The rate of proliferation decreased to 18.8% and 37.4% respectively. These results suggest that a transient rise in $[Ca^{2+}]_i$ is necessary for proliferation 24 hours after wounding.

INTRODUCTION

There are many events on the cellular level that depend on the synergistic contribution of cell motility and proliferation. For example, the process of wound healing involves the motility of cells into the open region created by the wound. However, cell motility alone is not sufficient if the wound is too wide. Cell proliferation or the growth of new cells is therefore necessary to fill the denuded space. Similarly, tissue morphogenesis cannot be initiated by cell motility alone and tumor metastasis also involves both cell motility and proliferation.

Previous work in the lab have shown that wounding of confluent monolayers of calf pulmonary artery endothelial cells (CPAE) induces a transient rise in $[Ca^{2+}]_i$ that travels for a short distance through the monolayer. This transient $[Ca^{2+}]_i$ wave was shown to be a rate limiting factor in cell motility measured hours after the initial stimulus. The source of this rise in $[Ca^{2+}]_i$ came from both Ca^{2+} influx and release from intracellular stores (Sammak et al., 1997). Kohn, et al have also shown that the influx of Ca^{2+} from the extracellular space is a necessary component of cellular adhesion pathways which regulate cell motility (Kohn et al., 1995). The induction of endothelial cell motility is an important event which is required for the subsequent induction of cell proliferation (Coomber and Gotlieb, 1990). Calcium has also been shown to play a role in cell proliferation, but these studies were done using high concentrations of extracellular Ca^{2+} or other agonists as a stimulus (Whitfield et al., 1980). With our model, we have found that there is a single, transient but physiologically relevant Ca^{2+} signal which affects the induction of cell proliferation 24 hours after the initial mechanical stimulus. Understanding the mechanism behind this tight regulation of proliferation is important in preventing such deleterious events as tumor metastasis and birth defects.

METHODS/MATERIALS

General cell culture:

Calf pulmonary artery endothelial cells (ATCC, CPAE ccl209 Rockville, MD) were cultured in DMEM containing 20mM HEPES and 1% penicillin/streptomycin (Gibco LifeTechnologies, Grand Island, NY) supplemented with 10% FBS (Hyclone, Logan, UT). All tissue culture incubations occurred in an 8% CO$_2$ humidified incubator at 37°C.

Proliferation assays:

Endothelial cells were grown on glass coverslips (Corning Glass, Corning, NY) to confluency. On the day of the experiment, the media was replaced with one of the following solutions for 30 seconds: Hank's Balanced Salt Solution (HBSS) (Gibco LifeTechnologies, Grand Island, NY), 100µM Gd^{3+} (Sigma Chemicals, St. Louis, MO) in phosphate-free HBSS, 2.5mM EGTA (Sigma Chemicals, St. Louis, MO) in Ca^{2+}-free HBSS, and 2.5mM Ca^{2+} in HBSS. Mechanical wounds were then made using a rubber policeman to remove half of the cells on the coverslip. After 1.5 minutes, the HBSS was replaced with fresh media and the cells returned to the incubator. At 24 hours post-wounding, the thymidine analog, bromodeoxyuridine (BrdU), was added to a final concentration of 10µM and the cells were returned to the incubator. After 6 hours, the cells were fixed with cold ethanol:acetic acid (95:5) at -20°C for 1/2 hour. Immunocytochemistry was done using a mouse anti-BrdU primary antibody and peroxidase-conjugated goat anti-mouse IgG secondary antibody (Sigma Chemicals, St. Louis, MO). After incubation with the peroxidase substrate, 3,3' Diaminobenzidine Tetrahydrochloride (DAB, Sigma Chemicals, St. Louis, MO), images of the wounds were obtained using a cooled CCD camera (Photometrics, Tucson, AZ) controlled by the IPLab Imaging program on an inverted Nikon diaphot 300. The number of proliferating cells was measured using the NIH 1.6 Imaging program.

$$\%\ \text{proliferating cells} = \frac{\text{no. of BrdU incorporated cells}}{\text{total no. of cells}} \qquad (1)$$

RESULTS

First, to determine the time of peak proliferation in our cell model, control cells were wounded as described in HBSS then BrdU was added at 6 hr intervals from 0-36 hours post-wounding. The time during which most cells were proliferating was determined to be at 24-30 hrs post-wounding(results not shown). The control rate of proliferation was 74.5% during this time (S.D.=5.8, n=3 expts; Fig 1 and Fig 2). BrdU was added during this time interval for all subsequent proliferation assays. Interestingly, proliferation was induced in large part in cells located at the wound edge. Fewer cells one field away from the wound edge proliferated compared to the edge (15.7%, S.D.=5.64, n=5 expts).

To see if [Ca^{2+}]$_i$ played a role in the induction of cell proliferation, we blocked [Ca^{2+}]$_i$ elevation with 100µM Gd^{3+}, a calcium channel blocker, or 2.5mM EGTA, a calcium chelator. When extracellular Ca^{2+} was chelated using 2.5mM EGTA, the % proliferating cells decreased to 37.4% (S.D.=0.6, n=3 expts.; Fig 1, 2). A greater decrease in % proliferating cells was observed when the [Ca^{2+}]$_i$ elevation was blocked by 100µM Gd^{3+}, giving only 18.8% proliferating cells (S.D.=1.9, n=3 expts.; Fig 1, 2). Gd^{3+} and EGTA resulted in an approximately 75% and 50% decrease, respectively, in the % proliferating cells compared to the control, showing that an influx of [Ca^{2+}]$_i$ is necessary not only for cell motility (Sammak et al., 1997) but also for normal cell proliferation.

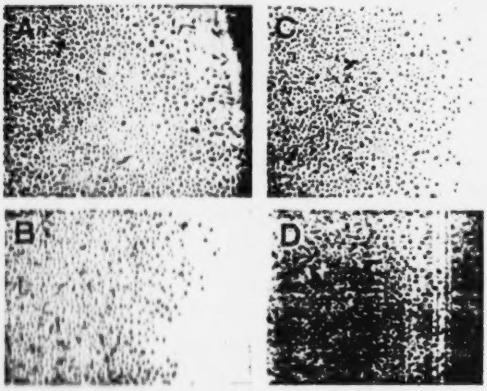

Figure 1: Calcium regulation of cell proliferation Panel A: In register phase contrast microscopy of the wound edge. Panels B-D: Bright field microscopy of BrdU stained nuclei. All cell nuclei were counter-stained with 0.1% thionin.
-Panel B: Control cells grown in DMEM containing 10% FBS (serum media) and wounded in HBSS buffer. 74.5% of cells at the wound edge were proliferating.
-Panel C: Cells wounded in 100uM Gd^{3+}, a calcium channel blocker. 18.8% of cells at the wound edge were proliferating.
-Panel D: Cells wounded in 2.5mM EGTA, an extracellular calcium chelator. 37.4% of cells at the wound edge were proliferating.

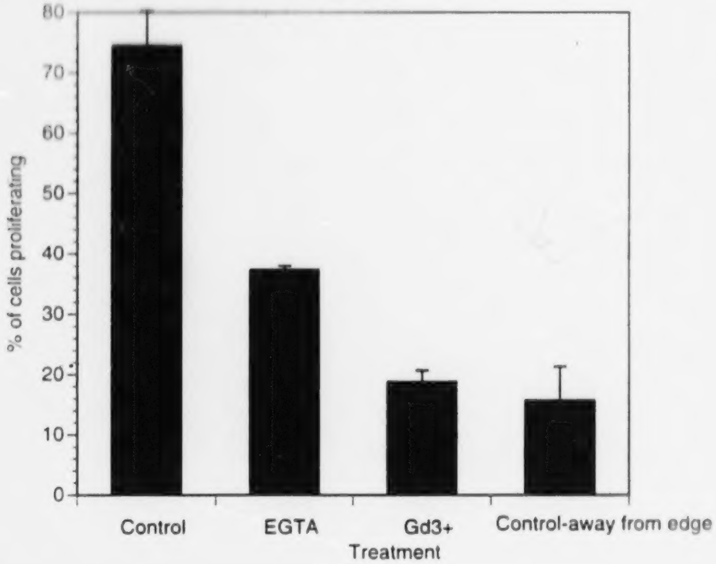

Figure 2: Summary of proliferation data Between 24-30 hr after the initial wound stimulus, 74.5% (S.D.=5.8, n=3 expts) of cells are proliferating. The induction of cell proliferation is also dependent on the Ca^{2+} induced upon wounding. Chelating extracellular calcium with 2.5mM EGTA decreases the % proliferating cells to 37.4% (S.D.=0.6, n=3 expts) while blocking calcium channels with 100uM Gd^{3+} decreased proliferation to 18.8% (S.D.=1.9,

n=3expts). Control cells one field away from the wound edge showed a decrease in proliferation to 15.7% (S.D.=5.64, n=5 expts).

Since normal cell proliferation was shown to require the rise in $[Ca^{2+}]_i$, we wanted to investigate the possibility of increasing the % proliferating cells by adding extra Ca^{2+}. We used $[Ca^{2+}]_i$ measurements with fura-2 to determine the concentration of Ca^{2+} to be used. Fura-2 measurements showed no increase in peak $[Ca^{2+}]_i$ levels with extracellular Ca^{2+} concentrations beyond 2.5 mM (P.O. Tran, personal communication). Mechanical wounding in HBSS containing 2.5 mM Ca^{2+} resulted in 100% of the cells at the wound edge proliferating. This result suggests that the addition of extra Ca^{2+} is sufficient to increase the rate of cell proliferation (Fig 3).

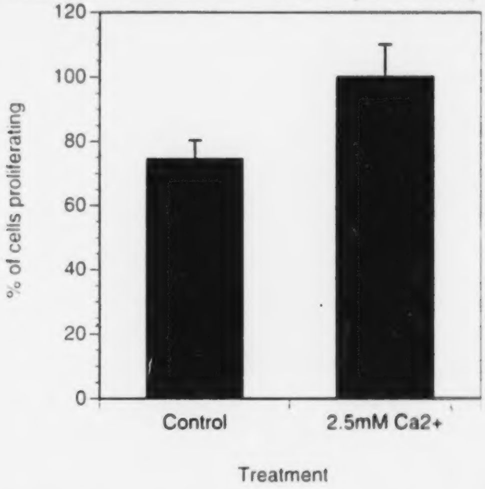

Figure 3: Effect of extra calcium. % proliferating cells was increased to 100% (S.D.=10, n=3 expts) when cells were mechanically wounded in 2.5 mM Ca^{2+} in HBSS.

DISCUSSION

Previous work in our lab has shown that mechanically wounding a monolayer of CPAE cells induces a $[Ca^{2+}]_i$ wave which travels through the monolayer. This $[Ca^{2+}]_i$ wave, however, only occurs in cells around the edge of the wound. Although this $[Ca^{2+}]_i$ wave has been shown to have a long-term effect on cell motility, the long-term effect on proliferation has not been clearly investigated. Since we found that peak proliferation occurred between 24-30hrs post-wounding, the single, transient Ca^{2+} signal induced upon mechanical wounding not only mediates long-term cell motility, but also the induction of proliferation. Although other work on Ca^{2+} signaling has shown that Ca^{2+} is required for cell motility (Kohn, et al., 1995 and Sammak, et al., 1997) and proliferation (Whitfield, et al., 1980), our model is unique in that it allows us to study a physiologically relevant change in Ca^{2+} and its effect on proliferation.

Our results suggest that a rise in $[Ca^{2+}]_i$ is a necessary component of cell proliferation induced upon wounding and extra Ca^{2+} in the extracellular buffer can increase the % of proliferating cells. Addition of different reagents used to block this $[Ca^{2+}]_i$ wave resulted in a reduction in % proliferating cells. Decreasing Ca^{2+} influx by blocking Ca^{2+} channels with Gd^{3+} reduced the % proliferating cells to 18.8% and chelating extracellular Ca^{2+} reduced the % proliferating cells to 37.4% compared to the control, of 74.5%. Increasing Ca^{2+}

1959

influx by wounding in HBSS containing 2.5mM Ca^{2+} resulted in an increase in the % proliferating cells to 100%. These results suggest that Ca^{2+} influx is required for the induction of cell proliferation following mechanical wounding. We also found that there was a spatial correlation between the wound-induced Ca^{2+} signal and cell proliferation. Only cells that experienced the increase in [Ca^{2+}]$_i$ were induced to proliferate 24 hours after the initial stimulus.

These findings on calcium signaling and its role in the induction of cell motility and proliferation have very important clinical relevance. Understanding the tight regulation of these cellular events is important in the control of such uncontrolled events as tumor metastasis and birth defects. Knowing how a single, transient signal affects long-term events can also aid in improving wound healing and tissue morphogenesis.

Dan E. Krane

ABSTRACT

The genomes of warm-blooded vertebrates comprise compartments with widely differing GC-contents relative to those found in cold-blooded vertebrates. A study of 110 orthologous loci reveals that evolutionary forces creating skewed amino acid fixational biases, particularly within genes embedded in GC-rich regions, operated independently in both lineages. Additionally, inferred ancestral protein sequences indicate that amino acid usage was already skewed to a lesser extent in a common ancestor of humans and chickens. Correlations between the GC-contents of human, chicken and frog genes used in this study further imply that the fixational biases that accompanied the creation and maintenance of contemporary isochore compartmentalization pre-dated the advent of homeothermy and did not originate independently in both the mammalian and avian lineages.

INTRODUCTION

The nuclear genome of warm-blooded vertebrates is a mosaic of long regions of homogenous base composition known as isochores. On the scale of megabases in length (Krane et al., 1991), mammalian and avian isochores typically fall into five or six discrete classes whose base compositions usually range from 35% to 65% G+C (Kadi et al., 1993). The much narrower ranges in the GC-contents of the genomic compartments of frogs (Bernardi and Bernardi, 1990a), a cold-blooded vertebrate, has been taken as evidence that compartmental heterogeneity in GC-content is a derived state that occurred twice and in association with the development of homeothermy in both the mammalian and avian lineages (Salinas et al., 1986; Cacciò et al., 1994).

The creation of genomic compartments with widely different GC-contents within warm-blooded vertebrates from portions of the compositionally homogenous genomes still found within cold-blooded vertebrates conferred a distinctive genome phenotype upon mammals and birds (Bernardi and Bernardi, 1986a). The widely different GC-contents of neo- and paleogenomes are correlated with several important aspects of genome structure, including gene concentration (Mouchiroud et al., 1991), average intron and gene length (Duret et al., 1995), recombination rates (Eyre-Walker, 1993) and distinctive preferential insertion of long and short repetitive elements (Soriano et al., 1981; Hardison et al., 1991).

The fixational biases that created isochores are thought to have been initially driven by thermostability-related selective advantages associated with increased GC-content (Bernardi and Bernardi, 1986a). Perhaps of greater selective importance, differences in GC-content are also accompanied by distinct differences in codon bias and amino acid usage (Bernardi & Bernardi, 1986a; Zoubak et al., 1995). For example, codons which contain only G or C in their first two positions specify amino acids (Ala, Arg, Gly, and Pro) which are thought to increase protein thermostability (Zuber, 1981; Bernardi and Bernardi, 1986a). Indeed, the relative frequency of the seven amino acids that contain only A or T in the first two codon positions have been found to be negatively correlated with GC-content at the first and second codon positions of genes (D'Onofrio et al., 1991). Opposite trends are found for the relative frequencies of the four amino acids whose codons are GC-rich (D'Onofrio et al., 1991).

Since homeothermy is thought to have been developed independently in both the mammalian and avian lineages (Carroll, 1988), it has been assumed that the creation of neogenomes must have begun independently in both lineages as well (Bernardi et al., 1985; Bernardi et al., 1988). In fact, relatively little is known about the duration that the responsible mechanism(s) operated (Bernardi et al., 1988) and even the time frame in which genome compartments first appeared has remained poorly defined. In order to directly examine these issues, we have performed a phylogenetic comparison of 110 orthologous loci from humans and chickens, using frogs and other cold-blooded vertebrate protein sequences as out groups.

MATERIALS AND METHODS

Selection of sequences: The 110 orthologous genes studied in this work represent all the loci for which complete coding sequences in humans (*Homo sapiens*) and chicken (*Gallus gallus*), as well as amino acid sequences for an out group (in 80 cases frog, *Xenopus laevis*) were found in an exhaustive search of the HOVERGEN database (release 21) of homologous sequences (Duret et al., 1994) and were available in either GenBank release 98+ (December, 1996) or PIR (December, 1996). Several additional loci were excluded from consideration due to an insufficient number of amino acid substitutions, disputes regarding their orthology, or because they were closely related paralogs of loci that had already been included.

Inference of amino acid substitutions: Amino acid alignments were made with the CLUSTAL V program (Higgins et al., 1992) and optimized by hand. Only unambiguously alignable homologous genic regions, excluding start and stop codons, were included in the analyses. Additional mammalian and avian protein sequences were used whenever available to resolve ambiguous substitutions in the human and chicken lineages. Amino acid substitutions, as well as the inferred ancestral sequences basal to the radiation of the human and chicken lineages, were scored by a parsimony approach using MacClade 3.05 (Maddison and Maddison, 1993).

The frequency of occurrence of amino acids whose first two codon positions are each either G or C ("GC-class" amino acids: Arg, Ala, Gly and Pro) and those whose first two positions are each either A or T ("AT-class" amino acids: Phe, Tyr, Asn, Lys, Leu, Iso and Met) was scored as two separate classes. Arginine codons were excluded from analyses of GC-class amino acids (Ala, Gly and Pro) and leucine codons were excluded from analyses of AT-class amino acids (Phe, Tyr, Asn, Lys, Iso and Met) since, it was only rarely possible to distinguish between arginine residues coded by GC-class codons (CGA, CGC, CGG, CGU) and intermediate-class codons (AGA, AGG) and leucines encoded by AT-class codons (UUA, UUG) could not usually be distinguished from intermediate-class codons (CUA, CUC, CUG, CUU).

RESULTS

GC-content at the third position of codons (GC_{III}) were highly correlated between loci in humans and chickens (Figure 1a; $r = 0.650$, $p << 0.01$), humans and frogs (Figure 1b; $r = 0.494$, $p < 0.01$) and chickens and frogs (Figure 1c; $r = 0.319$, $p < 0.01$). Values for GC_{I+II} were also highly correlated between humans and chickens ($r = 0.657$, $p << 0.01$), humans and frogs ($r = 0.669$, $p << 0.01$) and chickens and frogs ($r = 0.504$, $p < 0.01$). Further, there was a significant positive correlation between GC_{III} and the *net* number of substitutions which increase GC-class amino acids or decrease AT-class amino acids [(↑GC + ↓AT) - (↓GC + ↑AT)], ΔGC-ΔAT, in humans (Figure 2a; $r = 0.176$; $p < 0.05$) and chickens (Figure 2b; $r = 0.314$; $p < 0.01$).

The total number of substitutions across all loci which either increased the number of GC-class amino acids or decreased the number of AT-class amino acids (↑GC + ↓AT) is significantly different from the total number of substitutions which either decreased GC-class amino acids or increased AT-class amino acids (↓GC + ↑AT) in

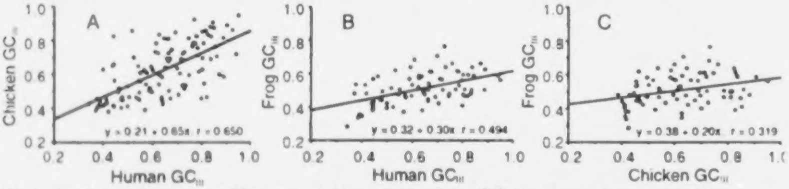

Fig. 1. Correlations between the GC-content of third codon positions (GC_{III}) between 110 loci in humans and chickens (A), 80 loci between humans and frogs (B), and chickens and frogs (C).

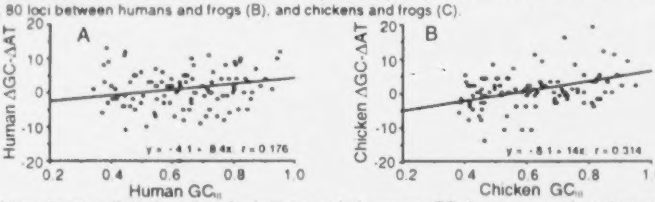

Fig. 2. Correlations between the net number of substitutions which increase GC-class amino acids or decrease AT-class amino acids (ΔGC-ΔAT) and the GC-content of the third codon positions (GC_{III}) among 110 loci in humans (A) and chickens (B).

the human lineage, however the difference is not significant in chickens (Table 1). Division of the loci into two classes, $GC_{III} < 57\%$ and $GC_{III} > 57\%$ corresponding to the L1 + L2 and H1 + H2 + H3 isochores, respectively (Mouchiroud et al., 1991), reveals that the significant excess of substitutions that increases GC-class amino acids and decreases AT-class amino acids in the human and chicken lineages is largely attributable to substitutions within their $GC_{III} > 57\%$ loci (Table 1).

A total of 38,415 amino acids (excluding start codons) across all loci at which substitutions could be unambiguously determined were considered during the course of these analyses. GC-class amino acids account for 7,407 of those residues in humans, 7,396 in chickens and 7,334 in the inferred ancestor of humans and chickens. AT-class amino acids account for 9,426 of those residues in humans, 9,475 in chickens and 9,500 in the inferred ancestor of humans and chickens. The distribution of AT-class amino acids (but not of GC-class amino acids) in the 55 human loci with the lowest GC_{III}-content and the 55 human loci with the highest GC_{III}-content is significantly skewed (Table 2).

Similar excesses of AT-class amino acids were found in the orthologs of the GC-poorest human loci in the chicken as well as within the inferred ancestor of humans and chickens (Table 2). The frequency of AT-class amino acids was negatively correlated with GC_{III}-content across all loci in humans ($r = 0.241$, $p < 0.01$) and chickens ($r = 0.207$, $p < 0.05$) though the frequency of GC-class amino acids was not significantly correlated with GC_{III}-content in either humans ($r = 0.032$, $p > 0.9$) or chickens ($r = 0.148$, $p > 0.1$).

Table 1. Substitutions which change the number of GC- and AT-class amino acids

	$\uparrow$GC + $\downarrow$AT	$\downarrow$GC + $\uparrow$AT	χ^2
Total			
Human	1582	1429	$\chi^2 = 3.596$, $p = 0.05$
Chicken	1438	1342	$\chi^2 = 1.658$, $p < 0.2$
$GC_{III} < 57\%$			
Human	552	521	$\chi^2 = 0.448$, $p < 0.6$
Chicken	585	640	$\chi^2 = 1.235$, $p < 0.3$
$GC_{III} > 57\%$			
Human	1030	908	$\chi^2 = 3.482$, $p = 0.05$
Chicken	853	702	$\chi^2 = 7.332$, $p < 0.01$

Table 2. Amino acid utilization in the GC_{III}-richest and GC_{III}-poorest human loci, their orthologs in chickens and in the common ancestor to chickens and humans

	GC-class amino acids			AT-class amino acids		
	Obs.	Exp.[a]	c^2 (p-value)[b]	Obs.	Exp.[a]	c^2 (p-value)[b]
Human						
GC_{III}-richest loci	3432	3360	3.596 (> 0.2)	4008	4275	16.721 (< 0.001)
GC_{III}-poorest loci	3975	4045	1.658 (> 0.2)	5418	5148	14.169 (< 0.001)
Chicken						
GC_{III}-richest loci	3406	3353	0.835 (> 0.3)	4008	4296	19.259 (< 0.001)
GC_{III}-poorest loci	3990	4039	0.587 (> 0.4)	5467	5174	16.599 (< 0.001)
Inferred ancestor						
GC_{III}-richest loci	3352	3327	0.187 (> 0.6)	4066	4310	13.779 (< 0.001)
GC_{III}-poorest loci	3982	4007	0.155 (> 0.6)	5434	5190	11.441 (< 0.001)

[a] Obtained from the number of amino acids at which substitutions could be unambiguously determined for each set and the observed overall frequency of AT or GC-class amino acids in humans, chickens and the inferred ancestor, respectively.

[b] Goodness of fit for equal distribution (df=1).

DISCUSSION

Isochore compartmentalization represents an integrated structural and functional feature of warm-blooded vertebrate genomes (Bernardi and Bernardi, 1986a). Establishing and maintaining these compartments has had significant evolutionary consequences for the genes that reside within them, particularly within warm-blooded vertebrates, including extensive modification of codon usage and amino acid composition (Bernardi and Bernardi, 1986a; Zoubak et al., 1995). Density gradient and hybridization experiments have revealed that dramatic differences exist between the compositional patterns of both mammals and birds relative to those of cold-blooded vertebrates (Bernardi et al., 1988; Bernardi and Bernardi, 1990a; Kadi et al., 1993). The absence of compositionally distinct, gene-rich neogenomes in primitive vertebrates as well as within reptiles (Bernardi et al., 1988; Bernardi and Bernardi, 1990a) has suggested that the origins of GC-rich compartments within birds and mammals were independent and coincident with their development of homeothermy.

The correlation of GC_{III} values observed between these species (Figure 1) implies that differences in the GC-content of the loci we have analyzed began to be established and maintained before birds and mammals last shared a common ancestor. Variations in GC_{III}, which consists predominantly of synonymous polymorphism due to overlap in the genetic code, should be subject to much less selective constraint than in $GC_{I,II}$, since changes in the first two nucleotides in a codon are more likely to result in amino acid changes and thus protein structure and function. Consequently, GC_{III} is likely to be a sensitive indicator of regional fixational biases at the DNA-level and its conservation suggests that similar forces have shaped the human, chicken and frog genomes since they last shared a common ancestor.

Evidence for a *genome*-wide trend toward a change in the relative abundance of amino acid classes was found across all human loci (Table 1). Analyses of fixational trends in humans since they last shared a common ancestor with rats (80 to 100 million years ago) show a similar but less dramatic skewing of the relative number of substitutions involving GC- and AT-class amino (Krane and Ayala, 1997) indicating that this trend may have been relatively constant over the past 280 million years. Similarly, in chicken loci there is a very significant trend towards decreasing the abundance of AT-class amino acids in favor of GC-class amino acids (Table 1).

The trends apparent in Table 1 are also consistent with the non-random utilization of amino acids observed within the GC_{III}-richest and GC_{III}-poorest human loci and their orthologs in chickens. AT-class amino acids were extremely under-represented in GC_{III}-rich genes and over-represented in GC_{III}-poor genes in both humans and chickens. This skewing of amino acid utilization appears to be a genome-wide phenomenon as the relative frequency of AT-class amino acids was found to be significantly correlated with GC_{III} content across all loci in humans and chickens (Fig. 2). The absence of similarly striking trends for GC-class amino acids implies that substitutions involving them are under greater selective constraint and/or that the mechanism responsible for the maintenance of isochore compartmentalization does not act as strongly upon them.

Of particular interest is the fact that amino acid utilization of the inferred common ancestor of humans and chickens displays a very similar though less dramatic skewing of AT-class amino acid utilization to that seen in its descendants (Table 2). Hence, modern-day correlations between amino acid utilization and GC_{III} content are attributable to significant differences between loci that were already established prior to the divergence of mammals and birds approximately 280 million years ago (McMenamin, 1987). This, together with the correlation between the GC_{III} contents of human, chicken and frog genes, indicates that the fixational biases that have operated within the human and chicken lineages (Table 1) may simply reflect a continuation of an ancient trend that originated very early in (or even before) the history of terrestrial vertebrates some 360 million years ago (McMenamin, 1987).

Two explanations have been postulated to account for the development and maintenance of isochores. First, the GC-contents of non-coding sequences and synonymous codon positions may have been indirectly altered by a mechanism whose primary selective advantage was associated with alterations of the amino acid composition and thermostability of proteins (Bernardi and Bernardi, 1986a; Perrin and Bernardi, 1987). Alternatively, regional differences in base composition could have arisen from a differential accumulation of mutations that are not adaptively-driven (Filipski, 1987; Sueoka, 1988).

Trends contrary to those of the major shift in the rat lineage (Krane and Ayala, 1997) and the existence of dramatically skewed amino acid utilization prior to the development of homeothermy and a corresponding increase in average body temperature undermine the first hypothesis' ability to account for the creation and maintenance of the neogenome within warm-blooded vertebrates. Not only does skewed amino acid utilization pre-date the divergence of humans and chickens, fixational trends over the past 280 million years appear to have primarily affected AT- and not GC-class codons.

The creation of neogenomes has been typically associated with the onset of a regionally acting, relatively short-lived GC-enriching substitution bias (Perrin and Bernardi, 1987; Bernardi et al., 1988). Our analyses indicate however that the shift in genomic GC-content began well before the divergence of humans and chickens and that the differences between the GC-rich neogenome and GC-poor paleogenome have continued to be accentuated since that time. Apparently "compositionally conservative modes of evolution" (Bernardi et al., 1988) may simply be due to the parallel and gradual accumulation of substitutions in several independent lineages while "abrupt transitions" in genome composition may result from the inactivation of the mechanism(s) responsible for those biases early in the history of some lineages.

ACKNOWLEDGEMENTS

We thank Adam Skepner for his assistance in determining the GC-contents of genes and construction of multiple alignments.

Abstract:

Thallium (Tl), a heavy metal causes neurotoxicity to rodents and humans. Since Tl and potassium (K) have similar ionic radii, Tl alters K-dependent processes such as inhibi-tion of cellular respiration, and disruption of calcium homeostasis. In this study *in vitro* effects of Tl^{+} and Tl^{3+} on Ca^{2+}-dependent nitric oxide synthase (NOS) activity as measured by a radioactive method in which the rate conversion of ^{3}H-arginine to ^{3}H-citrulline was monitored and $InsP_3$ and $InsP_4$ receptors involved in intracellular and extracellular mobilization of Ca^{2+} respectively were assessed. At μmolar concentrations Tl^{+} (24-54%) and Tl^{3+}(10-98%) significantly inhibited NOS activity in cerebellum. A slight decrease in ^{3}H-$InsP_3$ binding (18-23%) by Tl^{+} (25-100 μM) but not Tl^{3+} was observed. However, at 100-400 μM concentrations both Tl^{+} and Tl^{3+} did not elicit any significant effect on ^{3}H-$InsP_4$ binding. These data suggest that Tl alters Ca^{2+}-homeostasis and nitric oxide (NO) production by inhibiting NOS activity resulting in neuronal dysfunction.

INTRODUCTION

Thallium, one of the most toxic heavy metals is absorbed through the skin and is widely distributed throughout the body and accumulates in bones, renal medulla and eventually in the central nervous system (19). Possible toxic mechanisms of Tl include ligand formation with protein sulfhydryl groups, inhibition of cellular respiration, interaction with riboflavin and disruption of calcium-homeostasis (12). Recently, Barroso *et al.* (1) have demonstrated that Tl-induced cerebellar histological lesions can be protected by prussian blue and D-pencillamine.

The exact metabolic 'lesion' in Tl-intoxication is not yet known. Earlier studies reported that Tl interacts with riboflavin and alters the energy generation mechanisms associated with flavoproteins (3). Thallium behaves quite differently from bivalent heavy metals like Cd^{2+} and Co^{2+}, which act as competitive calcium antagonists at the presynaptic nerve terminal (4). Tl^{+} is unique in possessing an affinity for the K^{+}-activating site that is 10 times greater than K^{+} (7). It has been reported that Tl^{+} can replace K^{+} in the activation of the Na^{+}-K^{+} ATPase (14). Oxidation of Tl^{+} to Tl^{3+} inhibits the ATPase of amine-storing granules, thus causing alterations in the catecholamine metabolism (19).

Though many of the neurotoxic aspects of thallotoxicosis have been described, yet, the primary basis for its neurotoxicity remains unknown. It has been shown that the receptor activation of PI pathway yields $InsP_3$ which regulates the release of Ca^{2+} from endoplasmic reticulum (ER). $InsP_4$, a phosphorylated intermediate of $InsP_3$ metabolism has specific receptors on ER and plasma membrane and is also involved in Ca^{2+} regulation (2). Any interference with the receptor binding and/or Ca^{2+}-release activity of these PI-derived second messengers can have an adverse effect on Ca^{2+}-homeostasis. Nitric oxide is synthe-sized from L-arginine by NOS. Many of the effects of endogenous NO when generated in small amounts are mediated through the activation of guanylyl cyclase (6). Activation of guanylyl cyclase by NO is involved in the control of vascular tone (13), renal function (10) and neural signaling (8). When generated in larger amounts. NO inhibits cellular DNA synthesis and blocks oxidative phosphorylation (5). In the present study, *in vitro* effects of Tl^{+} and Tl^{3+} on Ca^{2+}-mobilizing receptors and Ca^{2+}- and calmodulin-dependent NOS in rat brain has been investigated.

MATERIALS AND METHODS

Adult female Sprague-Dawley rats (300 ± 10 g) from the NCTR breeding colony were used in this study. Animals were housed 2 per cage under controlled conditions. Water and feed were provided *ad libitum*. Animals were sacrificed by cervical dislocation and the brains were removed. The cerebellum of the brain was dissected and stored at -70°C. To study the *in vitro* effects of TlCl (Tl) and $TlCl_3$ (Tl^{3+}) the cerebellum of rat was used.

^{3}H-InsP$_3$ Receptor Binding: ^{3}H-InsP$_3$ receptor binding was determined using the method of Worley *et al.* (17). Briefly, the tissue was homogenized in 50 volumes of buffer A (50 mM Tris-HCl, pH 8.3, 1 mM EDTA) pelleted by centrifugation (35,000 g for 10 min) and resuspended in 50 volumes of buffer A. The reaction mixture contained buffer A (without EDTA and passed through Chelex-100 column), 10 mg wet weight of tissue (0.6 mg of protein) and 2.5 nM [^{3}H]-InsP$_3$ (1 Ci/nmole) in total volume of 1 ml. Assays were incubated for 10 min at 4°C and stopped by centrifugation at 10,000 g for 5 min followed by aspiration of the supernatant. The tips of the microfuge tubes were cut and the pellets were suspended in Scintiverse BD (NEN/Dupont) scintillation fluid and radioactivity was determined. Nonspecific binding was determined in the presence of 1 μM InsP$_3$. Proteins were estimated according to the method of Lowry *et al.* (9).

^{3}H-InsP$_4$ Receptor Binding: ^{3}H-InsP$_4$ receptor binding was determined in the cerebellar membranes by the method of Theibert *et al.* (16). Briefly, the tissue was homogenized in 50 vols. of buffer A (50 mM Tris HCl, pH 7.4, 1 mM EDTA), pelleted by centrifugation (35,000 x g for 10 min) washed twice in buffer A and resuspended in buffer A. Binding assays contained approximately 300-600 μg protein and 10 nM [^{3}H]-InsP$_4$ in a total volume of 250 μl of buffer B (50 mM Tris HCl, pH 8.5, 1 mM ß-mercaptoethanol and the buffer is passed through chelex-100 column). Assays were incubated for 10 min at 4°C and stopped by centrifugation at 10,000 x g for 5 min. followed by aspiration of the supernatant. The tips of the microfuge tubes were cut and the pellets were suspended in scintillation fluid, and radioactivity was determined. Nonspecific binding was determined in the presence of 10 μM InsP$_4$.

Nitric Oxide Synthase Activity: The specific activity of NOS was measured by the method as described by Matsumoto *et al.* (11) with slight modifications. Briefly, the different regions of the brain were quickly dissected and homogenized in 0.5 ml of buffer (pH 7.2) containing 0.32 M sucrose, 20 mM HEPES, 0.5 mM EDTA and 1 mM dithiothreitol and centrifuged at 39,000 X g for 30 min. NOS activity was measured using 50 μl of supernatant incubated with 30 μl of reaction mixture containing the follow (final concentration): 1 mM NADPH, 2 mM calcium acetate, 1 μg of calmodulin, 60 μM tetrahydrobiopterin, 20 μM FAD, 20 μM FMN and 200 μM arginine and [^{3}H]-arginine (5 μCi/ml). After 10 min incubation at 37°C the reaction was terminated by the addition of 1 ml of HEPES buffer (20 mM, pH 5.5) containing 2 mM EDTA and 2 mM EGTA. The incubations were then applied to 1 ml Dowex AG 50 WX-8 columns (Na^{+} form) and eluted. (^{3}H)-L-citrulline was measured by liquid scintillation counting.

Statistical Analysis: The data were analyzed by an analysis of variance (ANOVA). A value of $P < 0.05$ was taken as significant.

RESULTS

In vitro effects of both Tl^{+} and Tl^{3+} were studied on ^{3}H-InsP$_3$ and ^{3}H-InsP$_4$ binding to their receptors in cerebellum of rat (Figs. 1 & 2). Tl^{+} but not Tl^{3+} elicited slight inhibition of ^{3}H-InsP$_3$ binding. The binding of ^{3}H-InsP$_4$ was not significantly affected by both Tl^{+} and Tl^{3+} even at high concentrations (100-400 μM). However, the Ca^{2+}-dependent NOS activity was significantly inhibited by both Tl^{+} and Tl^{3+} in a

concentration-dependent manner. Pre-incubation of cerebellar NOS with 0.1-1.0 mM of Tl^+ significantly decreased the specific activity in a concentration-dependent manner (Fig. 3). Maximum inhibition of NOS activity was observed at 1.0 mM. The calculated IC_{50} for Tl^+ was 700 μM. No further significant inhibition was observed at greater than 1.0 mM Tl^+. Similar inhibition of NOS activity was observed when pre-incubated with micromolar (10-250 μM) concen-trations of Tl^{3+}. The calculated IC_{50} for Tl^{3+} was 70 μM . These data suggest that NOS was more sensitive to Tl^{3+} as compared to Tl^+.

Inhibition of ^{3}H-$InsP_3$ binding by Tl^+ suggests slight suppression of $InsP_3$-induced Ca^{2+} release from ER. These results suggest that Tl^+ alters binding of ^{3}H-Inositol poly-phosphates by modulating the conformation of their receptor sites. The described effects of Tl^+ on $InsP_3$ will lead to Ca^{2+} imbalance with in the neurones. It is possible, to speculate that disturbance of intracellular Ca^{2+}-homeostasis due to altered key regulatory steps of PI pathway by Tl^+ may be partially responsible for Tl-related neurotoxicity (12). Lack of Tl effect on ^{3}H-$InsP_4$ binding to receptors on plasma membrane and ER suggests that Ca^{2+} release from $InsP_3$-releasable compartment was unaffected by both Tl^+ and Tl^{3+}. Inhibition of NOS activity could be attributed to Tl^+-inhibition of Ca^{2+}-influx in brain.The generation of NO is Ca^{2+}-and calmodulin-dependent and inhibition of NOS suggests possible blockade of calmodulin action by Tl.The decreased production of NO due to inactivation of NOS by Tl results in reduced formation of cGMP (18) and inhibition of cGMP-mediated NMDA receptors (15).

ACKNOWLEDGMENTS

This research was supported in part by an appointment of Dr. Chellu S. Chetty to the Faculty Research participation Program at the National Center for Toxicological Research (NCTR) administered by the Oak Ridge Institute for Science and Education through interagency agreement between the U.S. Department of Energy and the U.S. Food and Drug Administration. The authors are thankful to Dr. S.F. Ali, Division of Neuro-toxicology, NCTR, Jefferson, AR for providing assistance and laboratory facilities.

Nitric Oxide (NO) is a gaseous free radical that causes smooth muscle relaxation and increases capillary permeability. Nitric Oxide Synthase (NOS) is the enzyme that catalyzes the conversion of L-arginine to NO and L-citrulline. Three isoforms of this enzyme have been identified. Previous studies have shown NO is produced by the uterus during pregnancy. The purpose of this experiment was to determine the pattern of localization of the endothelial isoform of NOS (eNOS) during the pre-implantation period, Days 1 through 4 of pregnancy, and in delayed-implanting uteri before and 1 hour after exposure to estrogen. Although this study was not quantitative, the results indicate that uterine localization of eNOS is highest on Day 1 of pregnancy in the epithelial cells and decreases over time and that exposure to estrogen around the time of implantation induces a change in the pattern of expression.

BACKGROUND

Nitric oxide (NO) is a gaseous free radical that interacts with cells and produces a wide variety of responses (1). It has been shown NO modulates inflammatory responses, causes smooth muscle relaxation, vasodilation, and may increase vascular permeability (2).

The enzyme nitric oxide synthase (NOS) converts the amino-acid L-arginine to NO and L-citrulline. NOS has three different isoforms, each named after the region in which it was first discovered. Endothelial NOS (eNOS) was first found in endothelial cells. Inducible NOS (iNOS) was first found in activated macrophages. Brain NOS (bNOS) was first found in the central nervous system. The presence of NOS indicates nitric oxide production (2).

The eNOS and bNOS isoforms are both regulated by intracellular calcium levels via calmodulin activation and are produced constitutively, i.e. they are expressed at low levels at all times. On the other hand, iNOS, due to its higher affinity for calmodulin even when calcium levels are low, produces NO in large and continuous quantities until L-arginine levels become limiting (1).

Several days after fertilization occurs, implantation takes place. Implantation is the process by which a blastocyst attaches and penetrates the epithelial lining of the uterus. This is initiated on the evening of Day 4 of pregnancy in the mouse. The processes involved in initiation of embryo implantation in the uterus are very similar to those involved in tissue inflammation. Implantation requires increased capillary permeability at the site where the embryo first attaches to the uterus. It also requires the muscles of the uterus to remain relaxed to prevent expulsion of the embryo.

Previous studies in our lab have shown that pre-implantation uterine tissues (Days1-4) in culture produce NO. The levels are highest on Day 1 of pregnancy. In addition, in ovariectomized animals 1 hour after exposure to estrogen the production of NO increases over 3 fold. Previous work has shown that the eNOS isoform is present in the post -implantation uteri. In the stroma cells and in decidual cells of the endometrium in Days 5 ,7 and in the myometrium on Day 11. In addition the longitudinal smooth muscles stained positively on all three days (5, 7, 11).

The goals of this study were to determine if the endothelial isomer of NOS is present on Days 1 to 4 and in ovariectomized-delayed implanting mice before and after estrogen exposure, and in what cell types eNOS is produced. The eNOS isomer was used for the following reasons 1) Previous experiments in our lab indicate that pre-implantation uteri in culture consititutively produce NO. 2) Successful implantation requires increased capillary permeability at the site of blastocyst attachment. eNOS has been shown to increase capillary permeability (2).

METHODS AND MATERIALS

Animals - Adult female, CD-I strain, mice (20- 25g), Charles River Laboratories, Raleigh, North Carolina) were mated with males of the same strain to produce pregnancy. The presence of a vaginal plug indicates Day 1 of pregnancy.

For the induction of delayed implantation, female mice were ovariectomized early (before 10:30am) on the fourth day of pregnancy. They received progesterone (2mg/0.1 ml/mouse/day) for four days. On the fourth day of progesterone they received a single injection of E_2 (100ng/0.1 ml corn oil, St. Louis Mo, Sigma Chemical Co.) Animals were sacrificed and uteri were removed, on each day of pregnancy between 12-1pm, and prior to and one hour after estrogen treatment in delayed implanting mice.

Slide Preparation: Slides were acid-washed (100g dichromate, 1L water, 200 ml concentrated sulfuric acid), coated with Poly-L-lysine (25mg/500ml PBS) for 10 minutes, air dried and stored at 4°C.

Immunocytochemical localization of eNOS: Mouse uteri isolated on Days 1 through 4 and from delayed implanting mice were flash frozen in liquid nitrogen. In addition, heart and liver tissues were isolated and flash frozen from non-pregnant animals. The uterine tissues were sectioned (8 microns), immediately formalin fixed for 10 minutes and stored at 4°C. Immunocytochemistry was performed using the Zymed Histostain-SP kit (Zymed Laboratories Inc.; South San Francisco, CA; TABLE 1).

In brief, slides were incubated with primary antibody (rabbit polyclonal anti- mouse eNOS; Affinity Bioreagents ; Golden , CO), biotinylated secondary and then AEC substrate/chromogen mixture was applied. Positive staining is indicated by a red color. The slides were counterstained with hematoxylin. Negative controls where no primary antibody was added were run in parallel. Heart muscles was stained as a positive control. In addition, endothelial cells within uterine sections were utilized as an internal positive control. Sections from the small intestine were used as a mucous epithelial cell negative control.

RESULTS

All uterine sections examined showed the presence of eNOS in the endothelial cells. All the uterine sections examined from Days 1, 2, 3 and 4 of pregnancy stained for the presence of eNOS. However, the intensity and localization of staining varied. Days 1, 2 and 3 of pregnancy stained specifically in the epithelial cells of the lumen with some glandular staining (Figure 1 A, B, C). eNOS was not seen in the stromal or muscle layers on any of these days. The intensity of staining on Day 1 of pregnancy appeared to progressively decrease through Day 3 (Figure 1 C). However on Day 4 of pregnancy some animals exhibited different patterns of expression which included no staining, eNOS localization similiar to that seen on Day 1, or in the longitudinal smooth muscle and stroma (Figure 1 D & 1 E). In the delayed-implanting uteri at one hour after estrogen treatment there was some smooth muscle, glandular epithelial and stromal (primarily antimesometrial) staining also seen (Figure 2 A). Those delayed-implanting uteri that were not exposed to estrogen had only a little epithelial staining (Figure 2 B).

Sections obtained from the heart showed staining only in the endothelial cells lining the blood vessels and ventricles (Figure 2 C). This tissue was used as a positive control because eNOS is known to be produced in endothelial cells. As a negative control, tissue sections were obtained from the small intestine. No staining in the luminal epithelial cells was seen confirming that the eNOS antibody does not bind to mucosal epithelial cells non-specifically (Figure 2 D).

DISCUSSION

The results of this study indicate that eNOS is present in the uterus on all four days of pregnancy and in delayed-implanting animals. On Day 1 the expression of eNOS was seen in the epithelial cells especially of the lumen. On Day 2 & 3 similar patterns, albeit at lower intensities, were seen. On Day 4

BEST COPY AVAILABLE

some animals showed a pattern like Day 3 while others showed some smooth muscle staining. In the delayed-implanting mice after estrogen exposure the pattern of expression of eNOS increased and expanded to include stromal cells and longitudinal smooth muscle.

From these data it can be concluded that estrogen has an effect on the pattern of eNOS expression. A pre-ovulatory estrogen surge occurs on the evening of proestrus, before Day 1 of pregnancy (4-7). It is probable that this estrogen secretion induces the expression of the eNOS in uterine epithelial cells seen on Day 1 pregnancy. Uterine sections taken from Days 2 & 3 showed a lower intensity of staining than that seen in Day 1. This may be due to the decline in plasma estrogen levels from the peak at proestrus. On Day 4 of pregnancy the pattern varies with some animals having little to no staining of the lumenal epithelial cells while others show longitudinal smooth muscle and glandular staining. This change in expression may be caused by increasing progesterone levels superimposed upon by pre-implantation estrogen secretion (3). The pre-implantation estrogen surge occurs on Day 4 around noon and induces implantation. Uteri were obtained from Day 4 animals between noon and 1pm making it likely that some animals had already been exposed to the preimplantation estrogen surge while other had not. Therefore, the variation in expression may be due to the variation in timing of the estrogen secretion from mouse to mouse.

This conclusion is supported by data obtained from delayed- implanting mice. In delayed-implanting animals 1 hour after estrogen exposure, longitudninal smooth muscle and glandular staining was seen. Those animals not exposed to estrogen had only small amounts of eNOS staining. These data also correlate with previous work from our lab. In culture, estrogen increases production of NO in the delayed implanting uterus (8). During post-implantation period uterine tissues from Days 5, 7 and 11 of pregnancy stain positively for the presence of eNOS in the longitudinal smooth muscles. Thus, uteri previously exposed to four days of progesterone respond to estrogen by expressing eNOS in the longitudinal smooth muscle.

In conclusion these data supports previous work done in our lab which shows that nitrite production in uterine culture is high on day 1, declines on days 2, 3, and 4 and then following exposure to estrogen, increases. It appears that pre-implantation estrogen increases eNOS expression in uterine epithelial cells while the implantation-inducing estrogen surge causes stromal, glandular and longitudinal smooth muscle expression. This changing eNOS expression pattern responsible for the changing pattern of NO production. However, there are other isoforms of NOS and their expression patterns must still be determined.

Studies using animals that lack only one isoform of the eNOS enzyme have no fertility problems. Therefore, it seems likely that although eNOS is present in the preimplanting uterus, it is possible that other isoforms of NOS are present and are regulated by estrogen. However, since there is a distinct pattern of eNOS expression that changes in response to the estrogen surge that also induces implantation, it is probable that NO production is a regulator of early pregnancy.

ABSTRACT

Diabetes has a significant impact not only on the health of the individual affected, but also on the health care system of the United States. During recent years diabetes and obesity have increased at an alarming rate; 5% of the nation's population is currently affected and this number is increasing at a rate of 6% annually. Type I diabetics experience a variety of symptoms ranging from early onset of disease, polyuria, glycosuria, and most significantly hyperglycemia from the inadequate production of insulin by the beta cells of the pancreas. In a colony of CD-1 mice at North Carolina State University a new mutation for type I diabetes has been identified. Studies on these mice indicate that there are additional complications associated with this mutation not previously described in the literature. Preliminary histological observation has shown a reduction or disappearance of the beta cells in the Islets of Langerhans and chronic renal disease. Most notable is an obstruction of the urethra resulting in a massive dilation of the bladder, hydronephrosis, and hydroureter. Tests have indicated that this obstruction is the result of a bacterial infection which is responsible for the formation and accumulation of a pyoid substance that partially blocks the urethra. Consequently, the ability to urinate is dramatically decreased in affected mice. Copious amounts of bladder urine were collected from affected mice ranging from 1.0 ml to 2.0 ml in volume. Interestingly, a comparison of two affected mice showed that one was infected with *Escherichia coli* and the other with *Pasturilla multicida*. Histological description of the urethra and bladder from control and affected mice will be presented. The similarities between mouse and human type I diabetes indicate that this mutant mouse might serve as a significant diagnostic model for humans.

BACKGROUND

Diabetes is a chronic disorder of carbohydrate metabolism as a consequence of inadequate production of insulin by the beta cells in the pancreas. The disease is generally characterized by excessive urination and high blood glucose levels. Diabetes occurs in two forms which are type I and type II. In addition to hyperglycemia and polyuria type I diabetes is also characterized as having an early age of onset of disease (prepubescent), normal body weight, and insulin dependency. In comparison, type II diabetes is characterized as being insulin independent, obese, and usually it appears after puberty. An affected family of CD-1 mutant mice show a type I diabetic phenotype and obesity apparently due to a mutation in the gene expressing the leptin receptor. In combination to being obese, affected mice have distended bladders due to a urethral blockage. This characteristic has not yet been described in literature. The urethral blockage is due to an apparent sloughing of the bladder epithelium combined with the presence of bacteria in the urine.

METHODS

- Sterile extraction of bladder urine from control and affected mice.
- Collection of bladder, kidney, and pancreatic tissue from control and affected mice.
- Urine sample was placed on a chocolate agar plate and incubated overnight @ 37 °C. Representative colonies of bacteria were then chosen and identified by through specific biochemical patterns. (*with the assistance of Dr. Paul Orndorff, CVM*)
- Preparation and analysis of histological slides. (*with the assistance of Dr. Richard Miller, CVM*)

RESULTS

Escherichia coli was found in urine samples of two affected mice and Pasturilla multicida was present in the urine samples of four affected mice. Bacteria was notably absent from all control urine samples that were tested. In the pancreas there was a reduction or loss of the beta cells in the Islets of Langerhans of affected mice. Next, the kidneys of affected mice showed tubular dilation, pyelitis, hydronephrosis, and glomerulersclerosis. All affected mice with distended bladders that were examined displayed damage to the bladder wall, cellular sloughing into the bladder lumen, and hyperplasia of the transitional epithelium. Figure 1 illustrates the occurence of bladder enlargment among control and affected mice.

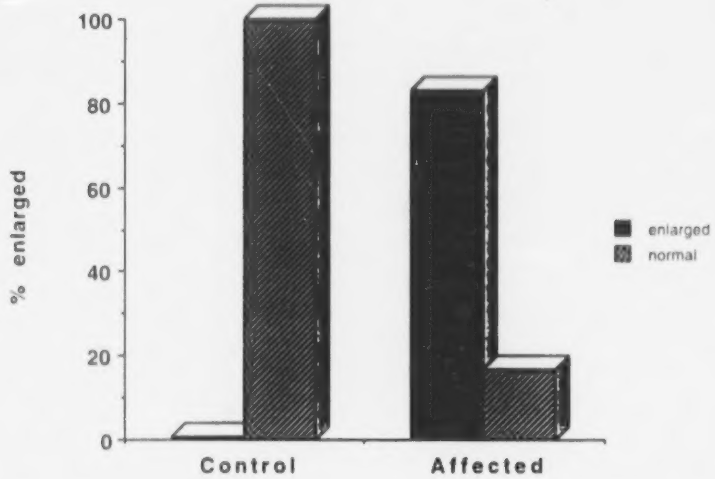

Figure 1: Incidence of Bladder Distention

CONCLUSION

There were several differences between the control mice and the affected mice. No bacteria was present in the bladder urine of control mice, in contrast the bladder urine of affected mice showed lesions of one of two species of bacteria. Next, histological comparison between affected and control mice showed clear lesions in all samples examined from affected mice, but none in control mice. None of the control mice had enlarged bladders, however 83% of the affected mice were afflicted with bladder distention ($p < 0.003$, Fishers Exact test). These results show a significant difference in the occurrence of bladder distention between diabetic/obese mice and normal mice, probably due to a bacterial infection.

Ustilago maydis is a plant-pathogenic fungus that infects corn to complete its life cycle. In order for two compatible strains to mate and infect the plant successfully each strain must have different alleles at two loci *a* and *b*. The *a* locus encodes a pheromone and receptor system which the cells use to locate each other. The *b* locus encodes a DNA-binding regulatory protein involved in the infection cycle. To date there has been no evidence that these loci have any function in vegetatively-growing cells, despite the fact that morphological differences are seen between strains with different alleles of *a* and *b*. In this experiment, cells from each of three strains of *U. maydis* were lysed by a variety of methods: acetone extraction, French Pressure Cell lysis, and mechanical disruption over glass beads. The resulting protein was then precipitated using cold trichloroacetic acid and separated using one-dimensional and two-dimensional SDS-polyacrylamide-gel-electrophoresis. Protein yields were consistently best using the mechanical disruption method. The French Press released some proteins from the cells. There was little or no protein recovered by the acetone extraction method. Although on two-dimensional gels, no obvious differences in proteins were seen between strains, this method of protein extraction makes analysis of patterns of protein synthesis much easier, and will allow for the study of developmentally-regulated proteins.

INTRODUCTION

The common corn smut disease, characterized by galls of teliospores on the meristematic parts of the plant host, is caused by the fungus *Ustilago maydis*. The two compatible laboratory mating strains of the haploid form, designated as FB1 and FB2, reproduce vegetatively by budding. They must mate, however, in order to infect their corn host and reproduce sexually. Mating of the two strains produces a dikaryotic infection filament, a long filament protruding from the mating pair (Banuett and Herskowitz, 1988, Snetselaar, 1993). This filament grows into the stigmas of the corn and ultimately infects the ovaries of the plant.

This organism is well-suited for in vitro study, because cells can be grown easily in the lab. Some mating-type functions can even be induced in vitro by mixing compatible strains in sterile water. The two cells form mating filaments which fuse forming a dikaryon, the first stage in the infection of the plant (Snetselaar, 1993). Most plant pathogens, such as wheat rust, cannot be grown in culture, let alone be induced to display mating behavior.

Mating and infection in the life cycle of *U. maydis* is controlled by two different genetic loci, designated *a* and *b*. The *a* locus has two alleles that encode a pheromone, and a pheromone receptor for the pheromone produced by compatible cells. The *b* locus has many alleles, and encodes a DNA-binding regulatory protein. For mating and infection to occur successfully, each strain must have different alleles at each locus. The FB1 strain has the genotype *a1b1*, while the FB2 has the genotype *a2b2*. Since they differ in the alleles at both loci, they can mate and infect corn successfully. It has been hypothesized that the *a* locus is primarily responsible for mating, while the *b* locus is primarily responsible for pathogenicity (Rowell and DeVay, 1955; Holliday, 1961). Thus, if two strains have the same allele at the *a* locus, no mating will occur between the strains, even if the *b* alleles are different. Similarly, if the *b* alleles of each strain are the same, no infection will occur, even if the *a* alleles are different.

To date, no roles have been established for these two genetic loci in vegetatively-growing cells of *U. maydis*. Wild-type strains and mutants in which the *b* locus has been deleted exhibit some morphological differences during vegetative growth, suggesting that these loci may play other roles in addition to their involvement in mating and infection. There may also be interactions between the products of the *a* and *b* loci and other loci, even in non-mating cells.

These interactions can be observed by analyzing the patterns of protein synthesis. This can be done by one-dimensional SDS-polyacrylamide-gel-electrophoresis (SDS-PAGE), which separates proteins on the basis of molecular weight. To provide further resolution of these proteins, two-dimensional SDS-PAGE can be performed, to separate proteins on the basis of both isoelectric point and molecular weight. The two-dimensional SDS-PAGE provides a more sensitive approach to separating proteins, as one thick band on a one-dimensional gel may in fact be several different proteins of similar molecular weight. Also, proteins produced in smaller amounts may be obscured on the one-dimensional SDS-PAGE, leaving only the proteins produced in larger amounts, such as structural proteins, visible. Since the different strains of *U. maydis* are expected to have the same structural proteins, there should be little difference on the one-dimensional gels. The two-dimensional gels, however, could yield much more information on the differences in proteins between these strains.

One problem that *U. maydis* presents is that protein extraction cannot be done by direct trichloroacetic acid (TCA) precipitation as is done with other types of cells, due to the thickness of the cell walls. Instead, the cells must be lysed mechanically, or by sudden pressure changes, as in a French Pressure Cell. This study has focused on the optimization of these disruption techniques to isolate total protein from *U. maydis* for subsequent analysis by one- and two-dimensional SDS-PAGE.

MATERIALS AND METHODS

Strains used and culture conditions

The laboratory strains FB1 and FB2 were used, as well as an FB2 mating-factor mutant (*mfa2*). This mutant strain does not produce pheromone due to deletion of the pheromone-encoding gene *mfa2*. Cell cultures were routinely grown on Difco potato-dextrose agar (PDA) plates for at least 48 hours before use. A flask containing 15ml of potato-dextrose broth (PDB) was aseptically inoculated with the appropriate strain of *U. maydis*, and allowed to grow at 28 degrees C with shaking at 150 rpm. After approximately 18 hours, one ml of this culture was used to inoculate 200ml PDB. This culture was then grown as described above for 24 hours. The cells were harvested by centrifugation at 1500 x g for 3 minutes, and resuspended in lysis buffer (1mM Tris, 0.1mM magnesium chloride) in one-tenth of the original volume.

Acetone extraction

Centrifuged cells were resuspended in ice-cold incubation buffer (90% acetone, 10% TCA, 0.07% Beta-mercaptoethanol) and incubated at -20 degrees C for 2 hours. They were then centrifuged for 15 minutes at 33,000 x g, and the supernatant was discarded. The cells were then washed twice with ice-cold acetone wash buffer (100% acetone, 0.07% Beta-mercaptoethanol) by incubating the cells for 30 minutes at -20 degrees C in the acetone buffer, centrifuging the solution at 1500 x g for 3 minutes, and discarding the supernatant. The resulting pellet was then air-dried in a vacuum-dessicator, and was weighed. Forty microliters of one-dimensional sample buffer (see below) were added per milligram of pellet. The solution was then centrifuged at 14,000 x g for five minutes to remove any debris. The supernatant was then run on a one-dimensional gel.

French Pressure Cell lysis

Cells in lysis buffer were subjected to a force of approximately 20,000 psi in the French Pressure Cell. Pressate was collected dropwise over ice. Typically, 20ml of cells in buffer would yield about 12ml of usable pressate. The pressate was then prepared for electrophoresis as described below.

Disruption by glass beads

About 500uL of cells in lysis buffer were added to an equal volume of glass beads in a screw-cap microfuge tube. The tube was then vibrated for three minutes in a Braun tissue disrupter (model #853303). The lysate was decanted from the beads into a clean tube. The beads were then washed with an equal volume of lysis buffer, and the wash was pooled with the lysate. The lysate was then processed as described below for either one-dimensional or two-dimensional SDS-PAGE.

Protein isolation

The lysate produced by either French Pressure Cell lysis or disruption by glass beads was collected and centrifuged at 27,000 x g for 10 minutes to remove unbroken cells and cellular debris. Proteins were then precipitated by mixing the lysate with two volumes of cold 50% TCA and centrifuging at 27,000 x g for 6 minutes. Pellets were then washed with cold 10% and cold 5% TCA, and then delipidated with ice-cold acetone. Pellets were allowed to air-dry, and were resuspended in the appropriate gel sample buffer. Proteins were then separated by either one-dimensional or two-dimensional SDS-PAGE.

One- and two-dimensional SDS-PAGE

Cellular proteins were prepared for one-dimensional SDS-PAGE by resuspending in Biorad sample buffer, heating at 50 degrees C for 2 minutes, centrifuging at 27,000 x g for 2 minutes to remove debris, and heating for 5 minutes at 90 degrees C.

Proteins were prepared for two-dimensional SDS-PAGE by resuspending in isoelectric focusing sample buffer. Samples were then loaded onto an isoelectric-focusing tube gel, and separated for 15 hours at 400V, followed by one hour at 1000V. The tube gels were then equilibrated with SDS-PAGE sample buffer and placed onto the second-dimension gels, where they were run for one hour at 125V, and then for 15 hours at 50 milliamps (O'Farrell, 1975).

All one-dimensional and two-dimensional gels were stained with Coomassie R-250 for two hours, and then destained (40% methanol, 10% acetic acid).

RESULTS

Pressate from the French Pressure Cell method and lysate from the disruption method were both centrifuged to remove debris and unbroken cells, yielding a viscous pellet, which was discarded. Addition of 50% TCA yielded another pellet, which was kept and washed. It was assumed that this second pellet was a mixture of chromosomal DNA and proteins.

Microscopic observation by Differential Interference Contrast (DIC) of cell suspensions after use of the French Pressure Cell indicated partial or complete cell lysis of a majority of cells. Many cell ghosts were seen and the number of intact cells was very low. Most cells appeared vacuolate after this treatment.

Comparison of the protein yields using the French Pressure Cell method or the acetone extraction method can be seen in Figure 1. The acetone extraction method resulted in a few, very faint bands on the one-dimensional gels. Processed pressate from the French Pressure Cell method using a comparable number of cells was run on the same gel. Numerous bands are clearly visible (Fig. 1).

Disruption by glass beads was compared with the French Pressure Cell method. The disruption method resulted in many more bands than the French Pressure Cell method (Fig. 2). DIC microscopy of the cell suspension at thirty-second intervals

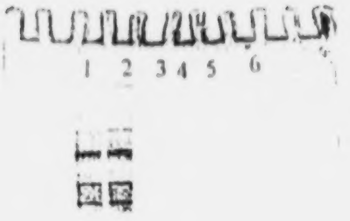

Fig 1 - One-dimensional SDS-PAGE of proteins isolated by French Press or acetone extraction. Proteins were isolated from FB2 cells using either the French Press or the acetone extraction method. Isolated proteins were separated using a 10% SDS-PAGE gel. Lanes 1 and 2 contain proteins isolated from these cells using the French Press. Lanes 3 through 6 contain proteins isolated from a comparable number of cells using the acetone extraction method.

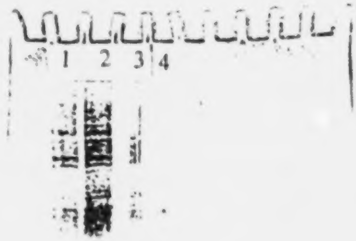

Fig 2 - One-dimensional SDS-PAGE of proteins isolated by French Press or tissue disrupter. Proteins were isolated from FB2 cells using either the French Press or the tissue disrupter and glass beads. Isolated proteins were separated as in Fig. 1. Lanes 1 and 2 contain proteins isolated using the tissue disrupter. Lanes 3 and 4 contain proteins isolated from a comparable number of cells using the French Press.

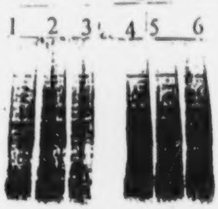

Fig 3 - One-dimensional SDS-PAGE of proteins isolated from FB1 and FB2 cells using the tissue disrupter. Proteins were isolated from comparable numbers of FB1 (lanes 4 - 6) and FB2 (lanes 1 - 3) cells using the tissue disrupter and glass beads. Isolated proteins were separated as in Fig. 1. Note the very similar yield obtained from both cell types. No differences in the number or relative intensity of any bands were detected between the two strains.

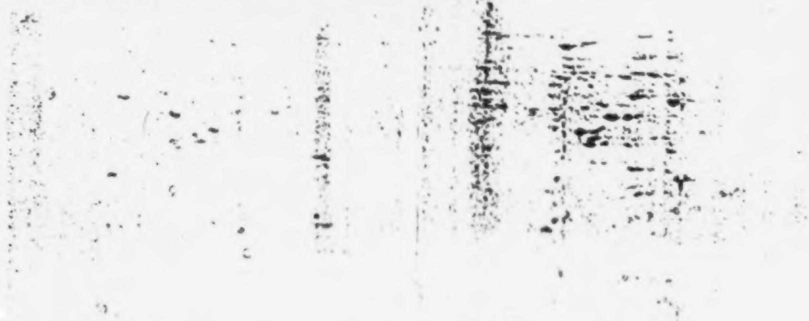

Figs. 4 and 5 - Two-dimensional gels of proteins isolated from cells of the mfa2 strain. The isoelectric focusing dimension is from left to right; the molecular weight separation is from top to bottom. Protein from approximately 3X as many cells was used in the gel in Fig. 4 compared to the gel in Fig. 5. Many spots of differing molecular weight and isoelectric point are evident. Note that the two gels are inverted relative to each other with respect to their isoelectric focusing dimensions.

showed that partial or complete disruption of cells occurred quickly. There was nearly complete disruption of all cells after three minutes of treatment. Disruption performed for longer than three minutes yielded little increase in the number of lysed cells (data not shown). Figure 3 shows the typical one-dimensional gel of proteins from cells lysed by this method.

Two-dimensional SDS-PAGE of proteins isolated from cells of *U. maydis* using the tissue disrupter produced a number of spots (Figs. 4 and 5). No differences in the total protein patterns were detected between the strains analyzed (data not shown).

DISCUSSION

Disrupting the cells using glass beads gave better yield of protein than either the French Pressure Cell or acetone extraction, even though these methods have been reported to work with other fungi. The amount of staining seen in disruption-extracted proteins, when compared to the French Pressure Cell method, was far greater. It also appears that the French Pressure Cell, although giving reproducible results, and certainly much more protein than the acetone extraction, did not release the same amount of proteins that the Braun tissue disruption method did. Numerous bands can be seen on the gels of disruption-extracted proteins, indicating the presence of different-sized proteins that the French Pressure Cell and acetone extraction methods did not efficiently extract in this experiment. Therefore, the tissue disruption method was chosen to isolate proteins for two-dimensional SDS-PAGE.

Thus far, two-dimensional SDS-PAGE of these proteins has only been used to visualize the total proteins present in the cells. It may be possible to use this technique to look for differences in protein content between different strains, as well as differences between mating and non-mating cells. Presumably, cells with morphological differences may have some differences in their patterns of protein expression.

This method can also be used to lyse cells whose proteins have been radiolabeled with a radioactive amino acid. This will be useful in the analysis of patterns of protein synthesis during the developmental cycle, and in a characterization of mutants in either the *a* or *b* locus. Labeling these cells with radioactive methionine has been tried, with moderate incorporation obtained thus far. Unfortunately, the levels of activity detected after labeling were insufficient for electrophoresis, but it is hoped that some progress can be made by altering the conditions of the labeling. This method of tissue disruption is preferred over the French Pressure Cell lysis method, not only due to apparently higher yield, but because the radioactive isotope is not aerosolized in this method, as it can be in the French Pressure Cell. Future directions for this experiment include a labeling of developmentally-regulated proteins using this method, and a characterization of different mutants.

ABSTRACT

The synthesis of superoxide dismutase (SOD: EC 1.15.1.1) in response to various cultural conditions was examined in *Candida albicans*, an opportunistic yeast which causes candidiasis in immunosuppressed patients. SOD plays an important role in protecting cells from the oxidative damage of superoxide radicals. Maximum SOD activity was found after 72 hrs of growth. The optimum pH and temperature for the SOD activity were 7 and 40°C, respectively. The major SOD activity was found in the cytosol fraction and the level of extracellular SOD was very low. The enzyme was stimulated to varying degrees by cholic acid, procaine and tocopherol. On the basis of inhibitor studies and other enzyme properties, the isolated enzyme from *C. albicans* is identified as copper and zinc superoxide dismutase.

INTRODUCTION

Superoxide dismutase (SOD; EC1.15.1.1) is found in most aerobic and many anaerobic organisms and is used to catalyze the superoxide radical, O^{-2}, to produce dioxygen and hydrogen peroxide $(2O_2^{-}+2H^{+}\text{->}O_2+H_2O_2)$ hence SOD plays a key role in protecting cells from the superoxide ion toxicity (18) which oxidizes membrane fatty acids and proteins and damage DNA (10). The concentration of SODs in an organism is dependent on the amount of oxygen exposure by the organism and its sensitivity to exposure to oxygen (2). SOD is a metallo-enzyme with a molecular weight range of 16 kDa to 26 kDa that is classified into three groups: copper-zinc, manganese, and iron (18).

Copper-zinc superoxide dismutase is mostly found only in eukaryotes in the mitochondrial inner membrane, cytoplasm, or chloroplasts, (9) but CuZnSOD has also been found in the prokaryotic symbiotic marine bacterium *Photobacterium leignathi* (19). CuZnSOD is a homodimer with a molecular weight of approximately 32 kDa with one subunit of copper and one of zinc (3). The zinc atom organizes the active site structure while also structuring the catalytic center. The copper atom work to reduce and oxidize the O_2 (19). MnSOD is found primarily in the mitochondrial matrix of prokaryotes (3) and eukaryotes (19) while FeSOD is found only in prokaryotes (3). MnSOD and FeSOD are usually dimers or tetramers composed of identical subunits (17). Structurally, MnSOD and FeSOD are very similar while CuZnSOD's structure is very different (18). The activity of SOD in response to temperature and pH and presence of oxygen has been studied in various species. In porcine Cu-Zn SOD (15), the catalytic activity was shown to be pH independent in the range of pH 5-9 but reversibly decreases at about pH 10. Enzyme activity was shown to drop linearly by increasing pH from 7.5 to 12. However in bovine enzyme, the activity decreased above pH 9.0 (1). The Cu-Zn SOD from vertebrate, fungi and plants was not affected by high temperatures (70°C) or by exposure to chloroform and ethanol. Elevated temperatures (42°C) induced FeSOD but not MnSOD in *E. coli* (8). In *E. coli* , cells grown on glucose as a sole source of carbon was found to contain lower amounts of SOD than cells grown on succinate, lactate or trypticase peptone medium (6). SOD activity is inhibited and stimulated by many substances. CuZnSOD is inhibited by cyanide and FeSOD is inhibited by peroxide while MnSOD is not affected by either of these but by ethanol in *Streptococcus suis* (11). In anaerobic *E. coli*, nitrate stimulated FeSOD activity at elevated temperatures while MnSOD was not affected (8). In *Saccharomyces cerevisiae*, CuZnSOD activity increased in the presence of copper while it is slightly inhibited by cadmium (16). Additionally, methanol induced SOD activity in methylotrophic yeasts (14).

It is well known that *Candida albicans* is a dimorphic pathogenic yeast capable of producing yeast (Y) or mycelial (M) forms in response to environmental conditions. The pathogenicity of this organism is linked to its dimorphic behavior. Since the target for SOD has been shown to be a component of immune and inflammatory cell responses, the enzyme has a potential role in the parasite-host interaction to modulate the host cell reactions. Since very little information has been available about SOD in *C. albicans* the present study has been made on its regulation in detail and the results are presented in this communication.

MATERIALS AND METHODS

Chemicals.

All the chemicals used in this study were reagent grade and purchased from Fisher Scientific, PA. and Sigma Chemicals, MO.

Organism and growth condition.

Candida albicans, (3153A) an opportunistic yeast was grown in Lee synthetic medium (12) as a shake culture in yeast form at 25°C. Cells were harvested by centrifugation and suspended in 50 mM potassium phosphate, pH 7.8 with 1mM EDTA. The cells were ground in pre-chilled mortar with liquid nitrogen. The disrupted cells were centrifuged at 18,000 x g for 20 min at 4°C. Culture filtrates concentrated by ultrafiltration, and cell-free extracts were used to measure the intracellular and extracellular SOD activities, respectively.

Superoxide dismutase assay.

SOD activity was determined spectrophotometrically at 560 nm by measuring the superoxide generated by xanthine-xanthine oxidase reaction and the rate of reduction by nitro blue tetrazolium (NBT). One unit of SOD activity is defined as the amount that causes 50% inhibition of the reduction of cytochrome C (13). Protein content of the extract was estimated by the method of Bradford (4).

Effect of carbon and nitrogen sources on growth and SOD activity

By growing *C. albicans* in Lee medium at pH 4.5 at 25°C, the effect of the carbon source on SOD activity was determined by substituting the carbon source on equimolar basis for glucose, with sucrose, lactose, and N-acetyl glucosamine individually. Similarly, the effect of the nitrogen source was also measured by substituting the nitrogen source for ammonium sulfate, with glutamate, arginine, glutamine, ornithine, or homoarginine. In the control, glucose and ammonium sulfate were used as carbon and nitrogen sources, respectively.

Effect of oxygen (aeration) on yeast growth and SOD activity

The effect of aeration on the growth of *C. albicans* was determined by growing yeast cells in Lee medium at 25°C at different volumes of media (15 ml, 25 ml, 50 ml, 100 ml, and 150 ml) in 250 ml Erlenmeyer flasks under stationary and shaking conditions.

Identification of SOD Type

To identify the type of SOD present in *C. albicans*, we measured the SOD activity in the presence of KCN, H_20_2, and NaN_2 at 1 and 10 mM concentrations.

Changes in SOD levels in yeast and pseudohyphal phases

The growth and intracellular activities of SOD in *C. albicans* in yeast phase were measured at 24 hour intervals for 120 hours at 25°C and in pseudohyphal phase at 37°C over a period of 12, 24, 36, and 48 hours. To measure the extracellular SOD activity the culture (spent) media was concentrated by ultrafiltration and used as enzyme source.

Effects of oxidants and antioxidants on SOD activity

The effects of various compounds such as glutathione, cholic acid, procaine, and tocopherol on SOD activity were determined by preincubating the enzyme with compounds in the reaction mixture. Their effect were measured on the enzyme activity by comparing with the control. Data was collected and the average of three trials is shown in the tables and figures.

RESULTS AND DISCUSSION

The enzyme isolated from the cell free extracts of *C. albicans* was identified as copper-zinc containing superoxide dismutase which was remarkably similar and distinguishable by only minor differences from the Cu-Zn SOD enzymes isolated from other organisms (3, 18, 19). Most of the SOD activity was detected from the cell free (soluble) extract and very little extracellular enzyme activity (<2% of total activity) from the culture media. The study on the influence of carbon source is shown in Figure 1 and reveals that the culture grown in glucose showed the greatest SOD activity. The culture grown in lactose media supported the most yeast growth but least support for SOD synthesis. Glutamate was found to the best nitrogen source for both the growth and enzyme production, but at the same time, the same generalization cannot be made for the rest of the tested nitrogen sources in that some of the other sources such as arginine and ornithine had more yeast growth but has less enzyme activity than glutamine (Fig. 2). To determine the optimum pH for *Candida* Cu-Zn SOD, enzyme was incubated in various buffers ranging from pH 4 to 10 in the reaction mixture for 10 min at 40 C. The optimum pH for the maximum enzyme activity was found at 7 which is very similar to other yeasts (15,16).

* represents the inhibition (<100%) or stimulation (>100%) of SOD activity

The effect of temperature on enzyme activity was determined by preheating the enzyme in the assay mixture for 10 min at temperatures from 25 to 60°C . Maximum activity was found at 40°C whereas only 30% activity remained at 50°C for 10 min. As illustrated in table 1, it is found that as the oxygen content decreases, the SOD activity increases which is concurrent with the behavior of SOD in *Anabaena cylindrica* (5). The study on the influence of various known SOD inhibitors was revealed that potassium cyanide was completely inhibited the SOD activity in *C.albicans* even at 1mM (Table-2). Earlier studies have been proven that only CuZn-SOD is inhibited by cyanide while the other two are not affected (9). Additionally it was shown that the enzyme was also partially inhibited by the peroxide and azide. Similar observations have been made with CuZn-SOD in other organisms (7). In *C. albicans*, addition of glutathione in reaction mixture inhibited the SOD activity whereas cholic acid and tocopherol stimulated the enzyme activity is stimulated (Table-3). No clear conclusions could be made about procaine effect due to the fact that the data were inconsistent.

The changes in yeast growth and SOD activity during the growth period are shown in figure 3. Maximum growth and enzyme activity was observed at 72 hours of growth. In pseudohyphae, the growth and SOD activity (Fig. 4) are increased steadily and reached a maximum at 48 hours.

Amphotericin B, which acts on the cytoplasmic membrane of the fungal cell, is the most effective treatment against *Aspergillus* infection. Extensive use of amphotericin B for the management of mycotic infection in recent years has significantly increased the potential for selecting amphotericin B-resistant clinical isolates. To study the possible mechanisms for the emergence of resistance to amphotericin B in *A. fumigatus* amphotericin B-resistant mutants in the laboratory were selected. A total of 18 colonies that grew in the presence of amphotericin B (8 µg/ml and 16 µg/ml) were tested for their susceptibility to amphotericin B, nystatin and various azoles by broth macrodilution technique. Approximately 55% of the isolates showed low level resistance to amphotericin B (MIC = 4 µg/ml) whereas the remaining isolates showed medium level resistance (MIC = 8-16 µg/ml). Subculturing of representative members of the low and medium level resistance groups showed that the resistance trait was stably expressed for several cycles of subculturing. None of the isolate showed cross resistance to other commonly used antifungals. These data suggest that amphotericin B resistant mutants of *A. fumigatus* can be isolated in the laboratory by a single step UV light induced mutagenesis.

INTRODUCTION

Aspergillus fumigatus is an opportunistic filamentous fungus that causes local as well as disseminated infection in immune compromised patients, namely, cancer patients undergoing chemotherapy (Hutter *et al.*, 1964; Iwen *et al.*, 1993; Wingard, 1995) organ transplant recipients (Pannuti *et al.*, 1991; Tolkoff-Rubin *et al.*, 1992; Morrison *et al.*, 1995) and AIDS patients (Pursell *et al.*, 1992; Khoo and Denning, 1994). Since *A. fumigatus* infection is often fatal in these patient populations, antifungals are increasingly used now to manage nosocomial mycoses in compromised hosts. Although fungal infection has increased significantly during the past 10 years (Bodey, 1988; Andriole, 1993; Beck-Sague *et al.*, 1993) the antifungal agents currently available to treat severe local and disseminated *Aspergillus* infection is very limited. Amphotericin B (AMB) which acts on the cytoplasmic membrane by interacting with ergosterol is the preferred choice of treatment for fungal infection, in particular against *A. fumigatus* because of its fungicidal activity. Increased use of AMB against fungal infection has greatly enhanced the chance for the emergence of resistance against this antifungal agent. We therefore sought to study the mechanism(s) for the emergence of resistance to AMB in *A. fumigatus* by selecting AMB-resistant mutants of *A. fumigatus* in the laboratory. The selection and characterization of AMB-resistant *A. fumigatus* isolates in the laboratory are described in this paper.

MATERIALS AND METHODS

Organisms and culture conditions: *Aspergillus fumigatus* W73355 (a clinical isolate obtained from the Detroit Medical Center; DMC) highly virulent to cause pulmonary aspergillosis in immune compromised mice was used in this study. Working cultures were maintained on peptone yeast extract glucose (PYG; peptone 1 g; yeast extract 1 g; glucose 3 g; per liter of distilled water) agar at room temperature. The primary culture obtained from the DMC was subcultured on PYG agar to assure the purity of the culture. Long term storage of the culture was done as conidial suspension in 25% glycerol at -70 °C.

Preparation of conidial suspension: Conidial suspension from *A. fumigatus* W73355 was prepared as previously described (Manavathu *et al.*, 1996). Briefly, for the preparation of conidial suspensions, cultures were grown on PYG agar plates for 6-7 days at 30 °C until the whole plate was covered with fungal growth, and the conidia were collected by flooding the agar surfaces with sterile growth medium (20 ml) followed by gentle scraping with a sterile rubber policeman. The resulting fungal suspension containing fragments of mycelia, small pieces of agar, and other cellular debris, was collected by aspiration. The aspirate was vortexed vigorously to release conidia from the conidiophores and was filtered through a sterile cotton plug fitted in a sterile Nalgene filtration funnel. In general, a single filtration step was sufficient to obtain a clarified conidial suspension. Failure to vortex the cell

BEST COPY AVAILABLE

suspension vigorously resulted in a poor yield of conidia as well as in the presence of large aggregates of conidia which often produces under-estimation of the cell density.

The cell density was determined by hemocytometer count. Each sample was counted four times independently, and the mean value of the quadruplicate was used for the calculation of the cell density. If the cell suspension was too concentrated for counting, a 1:10 dilution was prepared and the diluted suspension was used for the hemocytometer count. Under these conditions we routinely obtained approximately 1-3 x 10^7 conidia per ml when 20 ml of growth medium was used for resuspension. Fresh conidial suspension was used for the determination of minimum inhibitory concentration (MIC). However, conidia stored at 4 °C were completely viable for several months and the use of the conidia stored at 4 °C for several weeks yielded identical MIC values. The relationship between cell density estimated by hemocytometer count and the number of colony forming units was determined by plating appropriately diluted cell suspensions on PYG agar. The cell density estimation by colony forming units (CFU) production was approximately 10 to 20 percent lower than the value obtained by hemocytometer count. Although the determination of cell density by hemocytometer count is more time-consuming than the optical method (Espinel-Ingroff *et al.*, 1995), the hemocytometer count was preferable, since it seemed to provide a more accurate estimation of the cell density.

Construction of UV dose-survival curve: Fresh conidia were resuspended in PYG broth at a cell density of 1 x 10^6 conidia per ml (total of 20 ml) in a standard size (100 mm in diameter) petri dish. The conidial suspension was exposed to a UV lamp (Model UVL-21 Blak Ray Lamp, Longwave UV-366 nm, Ultraviolet Products, Inc., San Gabriel, CA) held at 6 inches from the bottom of the petri dish by a retort stand. Aliquots of the cell suspension were removed at various time intervals, diluted appropriately (100 fold serial dilutions), and 0.1 ml aliquots were spread on PYG medium for growth. CFU were estimated after 48 hr of incubation at 35 °C. The number of CFU per ml was plotted against time of exposure to estimate percent survival.

Selection of resistant colonies: Conidial suspension was exposed to UV irradiation as described above for 6 hr (≈ 90 percent cell death), collected by centrifugation, washed and resuspended in fresh PYG medium (1 x 10^8 conidia per ml) and 0.1 ml aliquots were plated (estimated to have ≈1 x 10^6 viable cells) on PYG agar containing 8 µg per ml and 16 µg per ml AMB. The plates were incubated at 35 °C in plastic sleeves for 7 days and colonies that grew on the plates were collected and stored as individual cultures for further study.

MIC determination: Conidial suspensions were prepared from colonies selected on the AMB containing PYG agar plates and the MICs of various antifungal agents for the AMB-selected isolates were determined as described previously (Manavathu *et al.*, 1996). Briefly, fresh conidia were collected from *A. fumigatus* and *A. niger*, and resuspended in PYG medium at a density of 2 x 10^4 conidia per ml. Two times the required concentrations of the drugs were prepared in PYG medium (0.5 ml) by serial dilution in sterile 6-ml polystyrene tubes (Falcon 2054) and inoculated with an equal volume (0.5 ml) of the conidial suspension. The tubes were incubated at 35 °C for 48 hr and scored for visible growth after vortexing the tubes gently, or scraping the walls of the tube followed by vortexing. The MIC was defined as the lowest concentration of the drug in which no visible growth occurred. The MIC determination for each isolate was repeated at least once, and the data were always within ±one dilution. The results given here is obtained for a typical experiment.

Kill curve experiment: Five ml of conidial suspension prepared in PYG broth (1 x 10^6 conidia per ml) was incubated at 25 °C in the presence of various concentrations of AMB (0 µg per ml to 4 µg per ml). At various time intervals 0.1 ml aliquots of the cell suspension were removed, diluted appropriately to obtain 10^2 to 10^4 fold dilution, and 0.1 ml aliquots were spread in duplicate on PYG agar plates. The plates were incubated at 35 °C for 48 hr and the number of CFU per ml of conidial suspension were calculated and plotted against the time of exposure to AMB to construct the kill-curve.

Antifungal agents: Ketoconazole (R41 400, Batch No. G3A747), miconazole (R14 889, Batch No. G5707), and itraconazole (R51 211, Batch No. STAN-9304-005-1) were obtained from Janssen Pharmaceutica, Belgium. Amphotericin B (Batch No. 20-914-29670) was obtained from the Squibb Institute for Medical Research, Princeton, NJ. Nystatin was obtained from Sigma Chemical Company, St. Louis, MS. All the antifungal agents were dissolved in dimethyl sulfoxide (DMSO) at a concentration of 1 mg per ml and stored as 0.5-ml aliquots at -20 °C. The frozen stock was thawed at room temperature and vortexed gently several times to ensure that any remaining crystals were completely dissolved before use. For MIC determination the following drug concentrations were used: amphotericin B, miconazole and itraconazole, 0 µg per ml to 16 µg per ml; ketoconazole, 0 µg per ml to 32 µg per ml; nystatin, 0 µg per ml to 25 µg per ml. Comparable concentrations of DMSO were tested to examine its effect on the growth of *A. fumigatus*. No detectable inhibition of growth occurred at the concentrations used.

RESULTS AND DISCUSSION

Effect of UV Irradiation: The effectiveness of UV mediated mutagenesis in *A. fumigatus* was investigated by monitoring the viability of mutagenized conidia by constructing a UV-dose response curve for the survival of conidia. As shown in Fig. 1, the survival of the conidia was inversely proportional to the time of exposure to the UV light. Within 6 hr of exposure greater than 90 percent of the cells were killed. UV mediated killing was effective only when the cells were physiologically active and underwent multiplication. For this reason, we incubated the conidia in PYG growth medium so that the effect of UV will be greatly enhanced as the conidia germinate. The fact that 6 hr of exposure to UV light was required to obtain ≥90 percent cell death was perhaps because of the initial period of inactivity of the conidia. The first morphological indication of the germination of dormant conidia (an increase in volume by swelling followed by the emergence of a small pertuberance) usually takes 3 hr of incubation in PYG at 25 °C. Since 6 hr of incubation resulted in ≥90 percent of cell death (which assures that there is a possibility that greater than 99.9 percent of the conidia will be affected by UV) we used 6 hr of irradiation under these conditions in all subsequent experiments for the selection of AMB-resistant *A. fumigatus*.

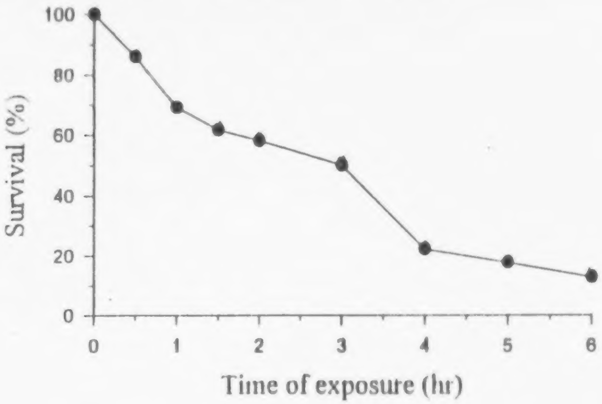

Fig. 1. Effect of UV irradiation on the survival of *A. fumigatus* conidia: Dose response curve.

Susceptibility studies: The susceptibility of eighteen *A. Fumigatus* colonies isolated on AMB containing plate to various antifungal agents is shown in Table 1. All the *A. fumigatus* isolates selected on AMB containing agar plate showed significantly higher MIC values for AMB than the susceptible parent. The mean MIC value for the 18 isolates shown in Table 1 was 6.0 ± 3.14 µg per ml which was approximately 12 fold higher than that of the parent W73355. A comparison of the susceptibility of these isolates to other antifungal agents showed that a significant rise in the MIC was obtained only in the case of nystatin (NYS) that is structurally related to AMB (Fig. 2), but not to the azole family of compounds. A series of subculturing of the resistant isolates was performed followed by determining the susceptibility to AMB to assess the genetic stability of the resistance trait. Even after 6 cycles of subculturing for every isolate the same MIC of AMB was obtained indicating that the resistance trait is genetically stable.

Table 1. Susceptibility of AMB-resistant laboratory isolates (n=18) of *Aspergillus fumigatus* to various antifungal agents

Antifungal	Mean MIC (µg/ml) ±S.D.	Range of MIC value	Fold increase in MIC
AMB	6.0 ± 3.14	4-16	12
NYS	10.06 ± 4.85	6.25-25	6.44
ITZ	0.63 ± 0.27	0.25-1	2.52
KTZ	11.11 ± 4.01	8-16	1.38
MCZ	2.44 ± 0.85	2-4	1.22

BEST COPY AVAILABLE

Note: MICs (µg/ml) of AMB, NYS (nystatin), ITZ (itraconazole), KTZ (ketoconazole) and MCZ (Miconazole) for the AMB-susceptible parent W73355 were 0.5, 1.56, 0.25, 8 and 2, respectively. The fold increase in MIC was calculated by comparison with the MIC of the respective antifungal for the susceptible parent strain.

Kill-curve studies: AMB is a fungicidal agent and exposure of the organism to this fungicide will kill the organism in a concentration dependent manner. The higher the MIC of an isolate is the lower the amount of killing. We therefore determined the fungicidal activity of AMB against two resistant isolates (AB8.6 and AB16.4) and compared the results with those obtained for the parent strain W73355. Four different concentrations of the drug representing 1 to 8 fold higher than the MIC of the susceptible parent W73355 but significantly below the MIC of the resistant isolates were included in our studies.

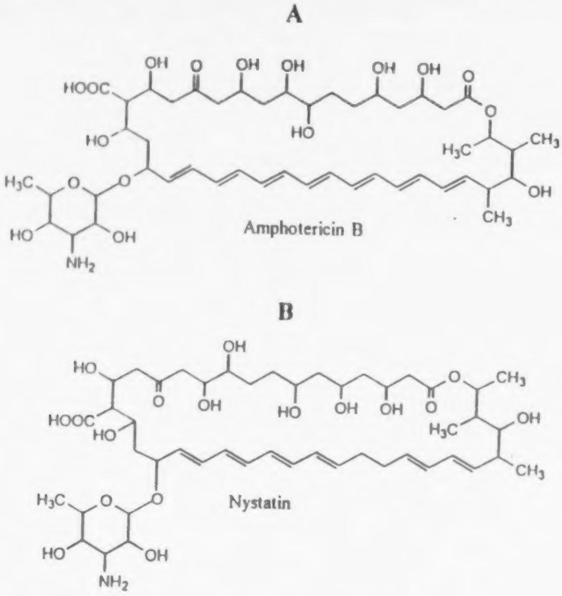

Fig.2. Chemical structures of amphotericin B and nystatin.

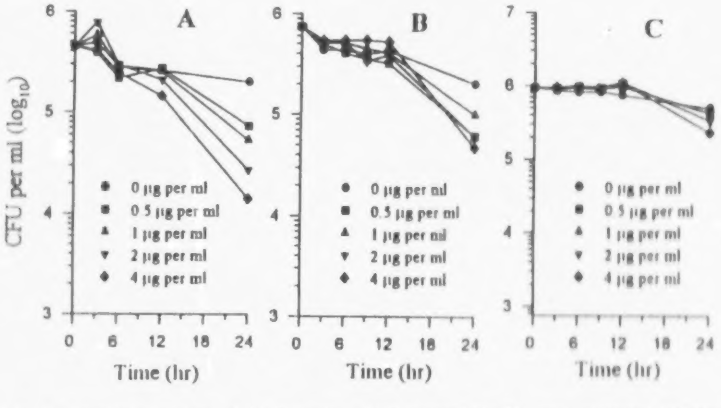

Fig. 3. Fungicidal activity of AMB against AMB-susceptible (A) and -resistant isolates (B and C).

As shown in Fig. 3, the susceptible parent W73355 (panel A) was killed more rapidly than the resistant isolates AB8.6 (panel B) and AB16.4 (panel C). For example, at 4 µg per ml

24 hr of exposure to the drug resulted in 93 percent killing of W73355 but only 76.5 percent and 35.8 percent for the resistant isolate AB8.6 and AB16.4, respectively.

Although AMB has been used as the premier antifungal agent for treating severe mycotic infection for the last 20 years, no significant level of emergence of resistance to AMB has occurred in the past. There may be several reasons: (1) Because the target of AMB is ergosterol, the end product of sterol synthetic pathway in fungi, the chances of acquiring mutagenic changes that lead to structural alteration of the target is less likely to occur. (2) Significant alteration to ergosterol molecule, which may impair the inhibitory activity of AMB, may also result in cell death. (3) Since AMB acts at the membrane level, its penetration to the cell is not required for its action. This may prevent the emergence of resistance because of a permeability barrier or by efflux proteins. (4) Last, but not least significance, is the fact that AMB may have more than one mode of action in which case emergence of resistance to AMB by counter acting all possible mode(s) of action is difficult. However, we have recently screened 180 clinical isolates of *Aspergillus* obtained from the DMC have been screened for their susceptibility to AMB. Several low level resistant isolates (MIC = 4 μg per ml) have been obtained suggesting that resistant mutants could emerge under selection pressure.

The in vitro susceptibility of 74 clinical isolates of *Aspergillus* (55 *A. fumigatus*, 10 *A. niger*, 3 *A. flavus* and 6 isolates not identified at the species level) to itraconazole and amphotericin B (two most commonly used antifungal agents against *Aspergillus* infection) was investigated using a broth macrodilution technique. All but two isolates of *A. fumigatus* were susceptible to itraconazole (mean minimum inhibitory concentration = 0.47 ± 0.37; range 0.25-2.0 μg/ml) whereas 54 of the 55 isolates examined were susceptible to amphotericin B (mean minimum inhibitory concentration = 1.28 ± 0.70; range 0.5-4.0 μg/ml). The three isolates less susceptible to itraconazole, and amphotericin B had minimum inhibitory concentrations of 2 μg/ml and 4 μg/ml, respectively. A comparison of the mean minimum inhibitory concentration values of itraconazole (2.7 ± 2.47 μg/ml) and amphotericin B (3.2± 1.73 μg/ml) for non-*fumigatus* isolates with those obtained for *A. fumigatus* showed that the former are approximately 6 fold and 2.5 fold less susceptible to itraconazole and amphotericin B, respectively. The data also suggest that clinical isolates of *Aspergillus* less sensitive to itraconazole and amphotericin B treatment can emerge in patients and such less susceptible isolates may contribute to the clinical failure of therapy against *Aspergillus* infection in immune compromised hosts.

INTRODUCTION

Members of the genus *Aspergillus* are opportunistic fungi that cause severe local and disseminated infection in immune compromised individuals, namely, cancer patients undergoing cytotoxic chemotherapy (Hutter *et al.*, 1964; Iwen *et al.*, 1993; Wingard, 1995), recipients of solid organ and bone marrow transplantation (Pannuti *et al.*,1991; Tolkoff-Rubin *et al.*, 1992; Morrison, *et al.*,1995) whose immune system is intentionally suppressed to prevent organ rejection and AIDS patients (Pursell *et al.*, 1992; Khoo and Denning, 1994) whose immune system is severely debilitated by human immune deficiency virus infection. Among the numerous species of *Aspergillus* described to date, only a selected few such as *A. fumigatus*, *A. niger* and *A. flavus* are the most commonly found species associated *Aspergillus* infection (Bodey, 1988; Andriole, 1993; Beck-Sague *et al.*, 1993). The main portals of entry for these organisms are the respiratory tracts and often they colonize these organs without causing apparent disease. At times the colonized organism is spread through the circulatory system to various organ systems and causes severe disseminated aspergillosis that often results in very high mortality rate among immune compromised patients.

Amphotericin B (AMB) and itraconazole (ITZ) are the most commonly used antifungal agents for the treatment of *Aspergillus* infection in man. AMB is a member of the polyene class of compounds known to interact with ergosterol of the fungal cytoplasmic membrane and brings about irreversible changes to the cell membrane which results in cell death. Thus, AMB is a fungicidal agent and remained as the premier antifungal agent for the treatment of aspergillosis. The main disadvantage of AMB is its severe toxicity to the renal function of the host at high doses. In contrast to the fungicidal activity of AMB, ITZ acts as a fungistatic agent by inhibiting the synthesis of ergosterol. The target of action of this compound is the cytochrome P450 dependent lanosterol 14-α-demethylase ($P450_{14DM}$), an enzyme that catalyze the removal of the methyl group on C14 of lanosterol for the subsequent synthesis of fecosterol. Although the exact mechanism is not fully understood, it is believed that azoles, including ITZ, bind to the active site of the enzyme thus preventing the binding and subsequent processing of the substrate. The mammalian system also contain $P450_{14DM}$ and catalyze the 14- α-demethylation of lanosterol, the affinity of the mammalian enzyme to ITZ (for that matter to all the azoles) is very low and only at very high concentration of the drug it inhibits the mammalian enzyme (Purcell *et al.*, 1995).

1993

The incidence of *Aspergillus* infection has increased significantly during the past 10years due to an expanding population of immune suppressed patients (Andriole, 1993; Beck-Sague *et al.*, 1993). In many Medical Centers in the United States management of fungal infection due to *Aspergillus* is a major clinical problem in bone marrow transplant, cancer and AIDS patients. The use of AMB and ITZ is significantly expanded for prophylaxis as well as treatment. Increased use of these antifungal agents resulted in the emergence of resistance to these drugs which often suspected to be in part for the failure of therapy in patients suffering from aspergillosis. A significant increase in the frequency of isolation of *Aspergillus* occurred in the Detroit Medical Center for the last 7 years. Thus, the main purpose of this study was to evaluate the in vitro susceptibility of various *Aspergillus* isolates obtained in the Detroit Medical Center for their susceptibility to both AMB and ITZ to evaluate whether drug resistance played any role in the failure of treatment in immune compromised patients. In this paper we describe the in vitro susceptibility to AMB and ITZ of all the clinical isolates of *Aspergillus* obtained in the Detroit Medical Center for a 2-year period from January 1994 to December 1995.

MATERIALS AND METHODS

Organisms and culture conditions: All the *Aspergillus* isolates used in this study were obtained from the Detroit Medical Center for a 2-year period from January 1994 to December 1995. Approximately 48 percent of the isolates were from bone marrow transplant patients, 32 percent from cancer patients and the remaining 20 percent from patients suffering from other serious medical problems (e.g. AIDS, metabolic disorder, etc.). The primary cultures received on potato dextrose agar slants were subcultured on peptone yeast extract glucose agar (PYG; peptone 1 g; yeast extract 1 g; glucose 3 g; per liter of distilled water) for 6 days at 30 °C for ensuring the purity of the cultures as well as for the production of conidia. Working cultures were maintained on PYG agar at room temperature, and long term storage of the cultures were done as conidial suspension in 25 percent glycerol at -70 °C.

Preparation of conidial suspension: Conidial suspensions from various *A. fumigatus* isolates were prepared as previously described (Manavathu *et al.*, 1996). Briefly, cultures were grown on PYG agar plates for 6 days at 30 °C until the whole plate was covered with fungal growth, and the conidia were collected by flooding the agar surfaces with sterile growth medium (20 ml) followed by gentle scraping with a sterile rubber policeman. The resulting fungal suspension containing fragments of mycelia, small pieces of agar, and other cellular debris, was collected by aspiration. The aspirate was vortexed vigorously to release conidia from the conidiophores and was filtered through a sterile cotton plug fitted in a sterile Nalgene filtration funnel. In general, a single filtration step was sufficient to obtain a clarified conidial suspension. Failure to vortex the cell suspension vigorously resulted in a poor yield of conidia as well as in the presence of large aggregates of conidia which often produces under-estimation of the cell density.

Cell density was determined by hemocytometer count. Each sample was counted four times independently, and the mean value of the quadruplicate was used for the calculation of the cell density. If the cell suspension was too concentrated for counting, a 1:10 dilution was prepared and the diluted suspension was used for the hemocytometer count. Under these conditions approximately 1-3 x 10^7 conidia per ml was obtained when 20 ml of growth medium was used for resuspension. Fresh conidial suspension was used for the determination of minimum inhibitory concentation (MIC). However, conidia stored at 4 °C were completely viable for several months and the use of the conidia stored at 4 °C for several weeks yielded identical MIC values. The relationship between cell density estimated by hemocytometer count and the number of colony forming units was determined by plating appropriately diluted cell suspensions on PYG agar. The cell density estimation by colony forming units (CFU) production was approximately 10 to 20 percent lower than the value obtained by hemocytometer count. Although the determination of cell density by hemocytometer count is more time-consuming than the optical method (Espinel-Ingroff *et al.*, 1995), the hemocytometer count was preferable, since it seemed to provide a more accurate estimation of the cell density.

MIC Determination: The susceptibility of various *Aspergillus* isolates to ITZ and AMB was tested by determing the MICs of the antifungals using a broth macrodilution technique according to the procedures of Manavathu *et al.*, (1996). Briefly, fresh conidia were resuspended in PYG medium at a density of 2 x 10^4 conidia per ml. Two times the required concentrations of the drugs were prepared in PYG medium (0.5 ml) by serial dilution in sterile 6-ml polystyrene tubes (Falcon 2054) and inoculated with an equal volume (0.5 ml) of the conidial suspension. The tubes were incubated at 35 °C for 48 hr and scored for visible growth after vortexing the tubes gently, or scraping the walls of the tube followed by vortexing. The MIC was defined as the lowest concentration of the drug in which no visible growth occurred. The MIC determination for each isolate was repeated at least once, and the data were always within ±one dilution.

Antifungals: ITZ (R51 211, Batch No. STAN-9304-005-1, Janssen Pharmaceutica, Belgium) and AMB (Batch No. 20-914-29670, Squibb Institute for Medical Research, Princeton, NJ) were dissolved in dimethyl sulfoxide (DMSO) at a concentration of 1 mg per ml and stored as 0.5-ml aliquots at -20 °C. The frozen stock was thawed at room temperature and vortexed gently several times to ensure that any remaining crystals were completely dissolved before use. Comparable concentrations of DMSO were tested to examine its effect on the growth of *A. fumigatus*. No detectable inhibition of growth occurred at the concentrations used. Since AMB is light -sensitive, the stock solutions and the MIC tubes were covered with aluminum foil to prevent from light exposure.

RESULTS AND DISCUSSION

Frequency of *Aspergillus* isolates in Detroit Medical Center: The frequency of isolation of *Aspergillus* in the Detroit Medical Center showed a steady increase from 1990-1996 (Fig.1). The overall increase in the number of isolates of *Aspergillus* was mainly due to increase in *A. fumigatus* isolates until 1995, but the frequecy of isolation of non-*fumigatus* species almost quadrupled in 1996. This significant increase in number of *Aspergillus* isolates in 1996 is perhaps attributable to the many construction projects taking place in and around the Detroit Medical Center. Although the incidence of *Aspergillus* infection is low compared to the *Candida albicans* infection rate, the high morbidity and mortality associated with *Aspergillus* infection make it a significant clinical problem.

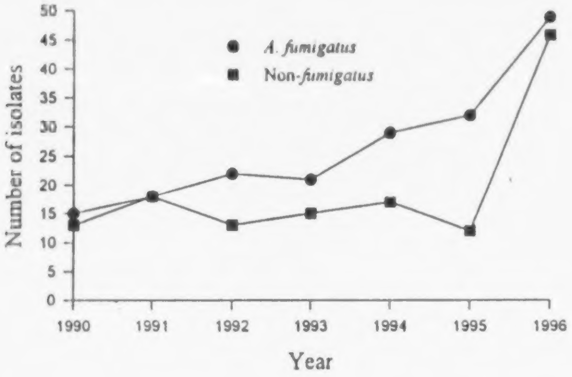

Figure 1. The frequency of isolation of *Aspergillus* species in the Detroit Medical Center from January 1990 to December 1996. The non-*fumigatus* group includes *A. niger*, *A. flavus* and non-speciated *Aspergillus*.

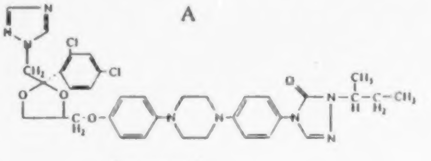
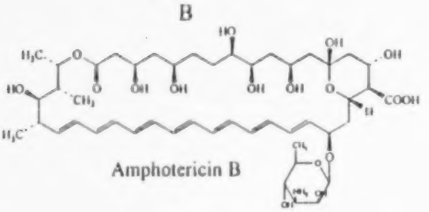
Susceptibility studies: The susceptibility of 55 *A. fumigatus* and 19 non-*fumigatus* isolates to ITZ (Fig. 2A) and AMB (Fig. 2B) was determined by the macrobroth dilution technique. The MIC determination for each isolate was repeated at least once and the values were within ±1 dilution of the value reported. The MIC values of ITZ for the 55 clinical isolates of *A. fumigatus* examined in our study is shown in Fig. 3A. The majority (87 percent) of the isolates had MICs of ITZ between 0.25 µg per ml and 0.5 µg per ml whereas the remaining 13 percent of the isolates had MICs between 1 µg per ml and 2 µg per ml indicating that ITZ MIC range for *A. fumigatus* is very narrow (mean MIC = 0.47±0.37 µg per ml). The susceptibility of *A. fumigatus* isolates to AMB is shown in Fig. 3B. Similar to the data obtained for ITZ, majority (63 percent) of the isolates had MICs between 0.5 µg per ml and 1 µg per ml. However, in contrast to the MIC values of ITZ, a significant number of isolates (35 percent) provided an MIC value of 2 µg per ml for AMB, and 1 isolate had an MIC of 4 µg per ml, generally considered to be low level resistance of clinical significance. The data obtained for AMB revealed that *A. fumigatus* isolates had a wider range of susceptibility to AMB (mean MIC =1.28 ± 0.70 µg per ml) compared to that obtained for ITZ.

The number of non-*fumigatus* clinical isolates obtained were lower than that of *A. fumigatus* during 1994-1995. In contrast to the low MIC values obtained for *A. fumigatus*, the non-*fumigatus* isolates were less susceptible to both ITZ (Fig. 4A) and AMB (Fig. 4B). The majority of the isolates showed an MIC value of 4 µg per ml for both compounds. The mean MIC values for ITZ and AMB were 2.70 ± 2.47 µg per ml and 3.2 ± 1.73 µg per ml, respectively indicating that the non-*fumigatus* species of *Aspergillus* were less susceptible to both ITZ and AMB.



Itraconazole



Amphotericin B

Figure 2. Chemical structures of AMB and ITZ. Both AMB and ITZ are hydrophobic molecules insoluble in aqueous solutions. AMB is an amphipathic molecule with hydrophobic and hydrophilic regions, and has the ability to interact with cell membrane. On the other hand ITZ possesses a polar head associated with a hydrophobic aliphatic tail which plays a key role in the proper binding and alignment of the molecule to the active site of $P450_{14DM}$.

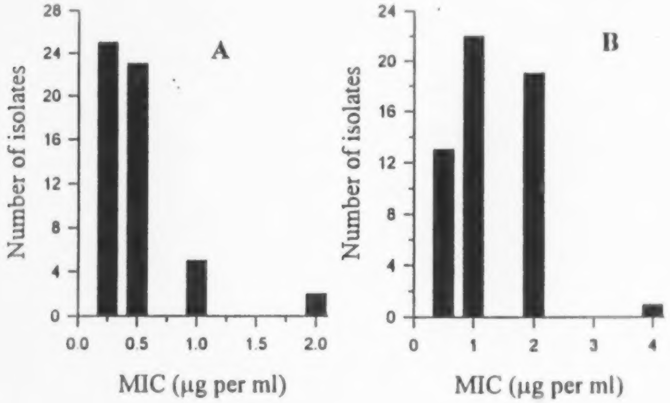


Figure 3. MIC pattern of 55 *A. fumigatus* isolates obtained from Detroit Medical Center during 1994-1995 to ITZ (A) and AMB (B).

The data on the susceptibility of various clinical isolates of *A. fumigatus* to ITZ and AMB showed that none of the 55 isolates we examined possessed high level resistance to either drugs. Only one isolate showed an in vitro MIC of greater than 2 µg per ml which is generally considered to be the breakpoint for these drugs. On the other hand, the susceptibility data showed that non-*fumigatus* species of *Aspergillus* in general are less susceptible to both ITZ and AMB, and almost 50 percent of the isolates showed an MIC ≥4 µg per ml which is above the break-point for these antifungal agents. Thus it is likely that aspergillus infection caused by non-*fumigatus* species may respond poorly to antifungal treatment with ITZ and AMB, and the presence of low and moderate level resistant isolates may be responsible for the failure of therapy.

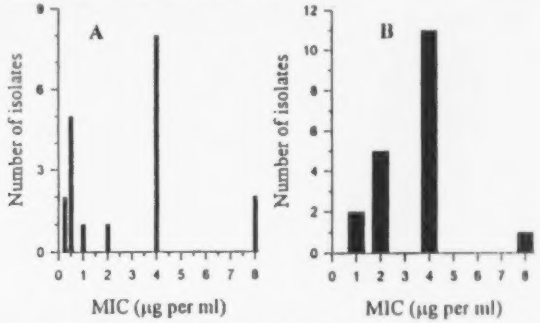

Figure 4. MIC patten of 19 non-*fumigatus* isolates of *Aspergillus* obtained from the Detroit Medical Center during 1994-1995 to ITZ (A) and AMB (B).

Aye-Aye Gruel Presentation Preference

Dr. Joan H. Eisemann

ABSTRACT

The Aye-ayes at the Duke University Primate Center (DUPC) practice sorting and selective feeding which leads to nutritional deficiencies. To prevent these deficiencies, the DUPC began feeding the Aye-ayes commercial primate chow in gruel form. The Aye-ayes still prefer their fruits and vegetables and eat little gruel. A preference trial was conducted using three container-types (bowl, bamboo, and coconut) to determine if gruel intake could be increased by its presentation method. Eight Aye-ayes, housed in four different enclosures, were used in the study. Preference trials were conducted on Thursday, Friday and Saturday, and replicated for three consecutive weeks. On a given day, each of the three container-types, filled with 364 g gruel, was represented in an Aye-aye enclosure, with the exception of one container-type, which was presented to two enclosures. Every week, each enclosure was exposed to each container-type once. Average daily consumption for the bowl, bamboo and coconut was 132.7 g, 163.4 g, and 178.5 g respectively. Planned comparisons were used to test for treatment differences. Consumption of gruel in the bowl was less ($P<.08$) than the average of the other two containers. There was no difference ($P>.10$) in consumption between bamboo and coconut. In comparison to the stainless steel bowl, Aye-aye gruel intake was increased when gruel was presented in a bamboo stalk or coconut shell, two containers natural to the Aye-ayes' environment.

BACKGROUND

In the past, the Aye-aye at the Duke University Primate Center (DUPC) were offered a diet which would meet their nutritional needs. However, their practice of sorting and selective feeding resulted in protein and essential vitamin and mineral deficiencies. To prevent these deficiencies, the DUPC began feeding the Aye-ayes commercial primate chow in gruel form (Haring, 1994). Despite the nutritional importance of the gruel, the Aye-ayes still prefer their fruits and vegetables and eat little gruel. In an attempt to increase their gruel intake, I wanted to present the gruel in different containers that enhance natural foraging behavior of the Aye-aye. In addition to increased gruel intake, the different containers will serve as a behavioral enriching device for the Aye-aye.

OBJECTIVE

To determine whether presenting the food in different containers could have potential benefits by increasing the Aye-ayes' gruel intake, and therefore providing the animals with a healthier diet. If the gruel intake is increased, the appropriate container could be incorporated into husbandry protocol practices.

HYPOTHESIS

The Aye-aye will have a greater intake of the gruel if presented in either a bamboo stalk or a coconut shell compared to the gruel presented in the stainless steel bowl. In addition, the intake will be higher in the bamboo stalk than the coconut shell because it requires more work for the Aye-aye to obtain the gruel.

METHODS

Number of animals/Housing A total of eight Aye-ayes were used in the experiment. They were housed in their existing enclosures, which are located indoors at DUPC. Two animals were in each enclosure. A total of four enclosures were used in the experiment. In order for the enclosures to be housed exclusively by Aye-ayes, all other nocturnal inhabitants were removed temporarily.

Diet The DUPC diet for the Aye-aye included primate chow, fruits, vegetables, grubs, and slightly boiled eggs. They were fed once daily between 1200 and 1400 hours. The gruel recipe included six cups of Mazuri primate chow (leaf eater primate chow), four and a half cups of hot water, and one-half cup of natural honey. The mixture was stirred until equal consistency was achieved. During this study, 364 g of the leaf eater primate chow gruel was used in each container. The Aye-ayes were given the usual offering of fruits and vegetables, grubs, and slightly boiled eggs. The only difference the Aye-ayes experienced was the gruel presentation method.

Treatments There were three compared variables; the stainless steel bowl, bamboo stalk, and coconut shell. The stainless steel bowl was approximately five inches in diameter and three inches tall. The gruel was placed inside the container. The bamboo stalk was cut just below each plant joint. This created a one-sided closed stalk or shaft of bamboo with one end opened. The gruel was spooned into the bamboo shaft until shaft was full. The gruel was packed into the shaft by 1) banging the closed end on the counter and/or 2) pushing the gruel into the shaft with a long spoon. Two bamboo shafts were needed to contain all 364 g gruel. The coconut shell container was prepared by using a jig-saw to cut out a quarter section of the shell. Then, the coconut meat inside was removed with a chisel. The gruel was spooned into the coconut.

Procedures An informal introduction period with each container variable was used to familiarize the animals with the container and therefore eliminate the novelty factor. The introduction period was completed the day before the preference trials. Both the bamboo stalk and the coconut shell were presented to the Aye-ayes with 364 g gruel for one day. During the introductory trial and for each preference trial, the appropriate container was placed in the same location on the Aye-aye enclosure food stand.

The preference trial intake measurements began on a Thursday. After randomizing the order of presentation of the variables, the stainless steel bowl was presented first to the animals in enclosure one and two. The coconut shell was presented first to animals in enclosure three, and the bamboo stalk was presented first to the animals in enclosure four. This presentation schedule allowed each container-type to be represented on a given day (See Table 1). Therefore, it eliminated any possible bias the animals might have demonstrated during any particular day. For example, if the temperature of the building changed, causing a constant environmental change throughout all four enclosures, then the effect was represented in all the container-type weigh-back measurements. The gruel intake measurements were taken every twenty-three hours at the same of the day (1300 hours). This allowed the presenter adequate time to prepare the containers for the next day's trial.

In addition, observations of the Aye-aye's feeding behavior were made and noted for a minimum of forty minutes after the containers were presented to the Aye-ayes. Enclosures four, three and one were observed on consecutive days for one week's trials. Enclosure two was not observed. The observational data was used to better understand the Aye-ayes feeding behavior, and it acted as background for future research experiments. No quantitative observational data was collected.

Table 1: Aye-aye Gruel Presentation Preference Trial Schedule

Week 1

Enclosure 1	Enclosure 2	Enclosure 3	Enclosure 4	
Bowl	Bowl	Coconut	Bamboo	Thursday
Coconut	Coconut	Bamboo	Bowl	Friday
Bamboo	Bamboo	Bowl	Coconut	Saturday

Week 2

Enclosure 1	Enclosure 2	Enclosure 3	Enclosure 4	
Coconut	Coconut	Bamboo	Bowl	Thursday
Bamboo	Bamboo	Bowl	Coconut	Friday
Bowl	Bowl	Coconut	Bamboo	Saturday

Week 3

Enclosure 1	Enclosure 2	Enclosure 3	Enclosure 4	
Bamboo	Bamboo	Bowl	Coconut	Thursday
Bowl	Bowl	Coconut	Bamboo	Friday
Coconut	Coconut	Bamboo	Bowl	Saturday

Specific data collection The data collected was the weight of the gruel before and after each specific container was presented to the Aye-ayes. The weight of the container, the gruel, and the combined weight of the two were recorded daily before the containers was presented. The next day only the combined weight of the container and the gruel were measured. The differences between the combined gruel and container weight before and after it was presented to the animals was equal to the total animal intake for that enclosure. All weights were recorded in a notebook and the differences were calculated. All measurements were in grams and were carried to the 1/10 of a gram. These measurements were taken at 1300 hours.

Data Analysis Data were analyzed by analysis of variance using a model containing enclosure, week, day and container as main effects. Planned comparisons were used to test for differences among containers. The average of the bamboo stalk and coconut shell were compared to the bowl. The data were considered significant if $P<.1$.

RESULTS

On one occasion, Wednesday, December 11, 1996, the Aye-ayes in enclosures three and four were removed from their enclosure and kept in temporary kennels while their enclosures were being thoroughly cleaned. The Aye-ayes were released back into their rearranged enclosures thirty minutes prior to the beginning of the second week's trails. The weighbacks for Thursday, December 12, 1996, were high (Enclosure three = 26.2 g consumed and Enclosure four = 22.4 g consumed) and obviously affected by the new environment adjustments. While observing the Aye-ayes initial feeding habits, it was evident that their behavior was abnormal. Instead of immediately feeding and foraging through their food at the food stand, the Aye-ayes paced along the branches of the enclosure. Increased inspection behavior; including smelling, third digit probing, and visual activity was observed. The Aye-ayes were distracted by the novelty of the new enclosure environment, which resulted in decreased food consumption. After reviewing all the data it was decided that intakes for

BEST COPY AVAILABLE

those days would not be included in the final data analysis because of their unjust representation of the Aye-ayes' normal feeding behavior.

Feeding behavior and container interactions were observed and recorded. Generally, the Aye-ayes ate all their eggs, fruits, and vegetables before approaching and eating their gruel. However, on some occasions gruel consumption was observed before some of the other daily offerings were eaten. Gruel consumption was never observed before any other Aye-aye food offerings. The Aye-ayes always first ate some other food offering before their gruel. Both the bamboo stalk and coconut shell had more physical contact than the bowl. In some cases the Aye-ayes bit the coconut shell through the bottom to get to the gruel. However, it was also observed that the Aye-ayes treated the coconut shell as a bowl and scooped the gruel directly out of the shell opening. The Aye-ayes removed both the coconut shell and bamboo stalk from the food stand, which sometimes lead to it being carried to the top of enclosure branches. This behavior was not observed with the stainless steel bowl. The numerical data supports these observations.

The average daily consumption for the bowl, bamboo and coconut was 132.7 g, 163.4 g, and 178.5 g respectively. Consumption of gruel in the bowl was less ($P<.08$) than the average of the other two containers. There was no difference ($P>.10$) in consumption between gruel in the bamboo and coconut.

DISCUSSION

Some possible errors were encountered during the preference trials. On one occasion, an uninformed DUPC technician removed the bamboo container from one enclosure and disposed of it. The containers were retrieved and the enclosure floors and food stands were checked extensively for any remaining gruel. All remains were weighed and recorded as weighbacks. After a number of hours, the gruel becomes dehydrated and hardens. This had two affects on the experiment. 1) This helped the gruel remain intact during its collection and disposal by the DUPC technician. The weighbacks for that day (Saturday, enclosure 1 and 2) should be accurate, although, it is recognized that errors in the results could have originated from the containers' temporary disposal. 2) The Aye-aye overall intake of gruel could be reduced when the gruel becomes dehydrated because of its hard physical characteristics. This is an area for further study. The gruel consistency which promotes the most Aye-aye overall gruel intake could be determined and applied to the results of this study. In addition, the introduction period could be extended to minimize possible increase in gruel intake because of a novelty factor. Also, the experiment itself could be extended to gather more data and hence decrease the possibility for error or chance. Finally, it is assumed that the Aye-ayes are in good health. The data could be inaccurate if an Aye-aye was in poor health and it affected its appetite.

Despite the above concerns, it can be concluded that in comparison to the stainless steel bowl, Aye-aye gruel intake is increased when gruel is presented in a bamboo stalk or coconut shell, two containers natural to the Aye-ayes' environment To ensure the Aye-ayes nutrition health and to increase their behavior enrichment, the bamboo stalk and coconut shell containers should be incorporated into husbandry protocol practices. Use of the stainless steel bowl as a gruel container should be avoided for the health benefits of the Aye-ayes. This is recommended because the Aye-ayes' proper nutrition is compromised when their gruel intake is lowered. In addition, future container types can be researched and compared to determine the container that best promotes Aye-aye gruel consumption.

Modification of the Binary TBP-DNA Complex by Pluramycins

Sameer Ambady

Drug Dynamics Institute
College of Pharmacy
University of Texas at Austin
Austin, Texas 78712-1024

Faculty Advisor:
Dr. Lawrence Hurley

ABSTRACT:

In this series of experiments we probed the TBP-DNA binary complex. We wanted to try and understand how a symmetric molecule like TBP could initiate asymmetric transcription. To do this, we used the pluramycin family of drugs as molecular probes to indicate Areas of conformational change in DNA. The DNA sequences we used were those of the Adeno-Virus Major Late Promoter (AdMLP-54mer) and the Human Myoglobin Promoter (HmP-64mer).

INTRODUCTION:

To gain an understanding of transcription, we must remember that eukaryotes possess three different type of RNA polymerases, RNA polymerases I, II, and III, each with its own function. The function of RNA polymerase I (RNAP I) is to transcribe ribosomal RNA. The function of RNA polymerase II (RNAP II) is to catalyze the synthesis of eukaryotic messenger RNA, and the function of RNA polymerase III (RNAP III) is to transcribe both transfer and ribosomal RNA (review 4-6). The functions of all three polymerases are aided through the recruitment of various other protein cofactors, collectively known as Transcription Factors (review 4-6). For RNAP II, which recognizes the TATA promoter, among the most important transcription factors is Transcription Factor IID (TFIID).

Transcription Factor IID contains the TATA-Binding Protein (TBP), and is the only transcription factor that has been found to be site specific and to bind directly to DNA (4). What makes TFIID, and TBP, an area of such intense interest is that TBP binds to the TATA promoter in an unusual manner. It recognizes and binds to DNA through the minor groove (1). This is very unusual since the majority of proteins interact with the major groove of DNA. The major groove of DNA has a larger number of possible chemical interactions. This makes it a much more attractive site for protein-DNA interactions. But TBP binds to the minor groove, and as a result of TBP binding, the DNA helix is unwound at the TATA region and bent towards the major groove (1). In addition to bending and unwinding at the TATA site, there is a widening of the minor groove to facilitate TBP binding (1, 6). This unique type of protein-DNA interaction and the radical conformational changes induced in DNA as a result of TBP binding, make it an area of great interest.

How TBP interacts to produce these unusual changes is equally unique. The 5' end of the B-form DNA molecule comes in contact with the C-terminal end of the TBP molecule (6). TBP inserts a pair of phenylalanine side chains between the first T-A:A-T of the TATA-box (1, 6). This insertion induces the B-form DNA molecule to unwind and present a smooth unwound minor groove to the rest of the TBP molecule (1, 6). The unwound minor groove interacts with the anti-parallel beta-sheets along the bottom of the TBP molecule, causing the helix to bend (1, 6) and allows the side chains of TBP to interact with the minor groove. Insertion of another pair of phenylalanines from the N-terminal end of TBP, between the last two bases in the TATA-box, cause the helix to return to B-form DNA (1, 6).

TBP is known to be a quasi-symmetric molecule, but binding of TBP leads to asymmetric transcription. This means there must be some kind of directional modification induced in the DNA helix, which allows a symmetric TBP molecule, bound to a symmetric DNA molecule, to initiate asymmetric transcription. This was the basic premise behind this series of experiments.

OBJECTIVES:

- To investigate how a symmetric molecule directs asymmetric transcription.
- To investigate the drug-modification cavity using varying flanking sequences and drug molecules having different substituent groups.

METHODS:

We took the different DNA sequences and 5' labeled them with ^{32}P. After labeling, we incubated some of the DNA with TBP and left some to act as the control. After allowing complex formation, we added either no drug, hedamycin, or altromycin B to the samples. We allowed time for drug modification to occur and then ran the samples out on a separation acrylamide gel. We eluted the control, the bound drug modified DNA and the free drug modified DNA and purified them. Next we ran a strand breakage assay and then ran out the samples on a sequencing gel and looked for areas of modification.

RESULTS:

The pluramycin family of drugs are known to be an antibiotic-antitumor family of drugs. They are cytotoxic to all cells but act preferentially upon cancer cells. The reason for this is unknown, but the mechanism through which they act is well documented. They are intercalating-DNA-alkylators which alkylate the N^7 of guanine (7). Because of this fact, they are often used as small molecular probes through which structural changes in DNA can be seen. This is how they were employed in our experiment.

In order to probe the changes induced by TBP, we used member of the pluramycin family of drugs as molecular probes. We isolated free DNA and DNA bound to TBP and treated them with hedamycin or altromycin B, in order to view areas of altered configuration.

The Stucture of Pluramycins and their Substituent Groups

	R_5	R_8	R_{10}
Hedamycin	H		Altromycin B		H	
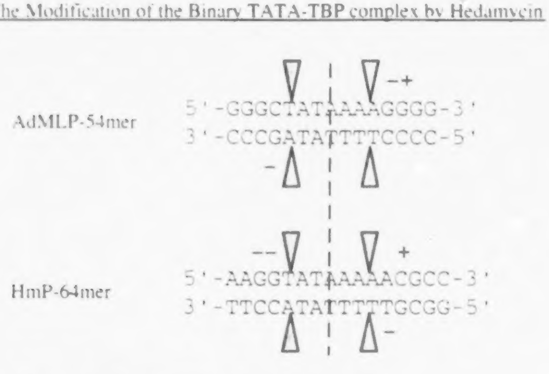
Figure 1: Structure of the Pluramycin Family and their Substituent Groups

In Figure 1 we can see the basic structure of the pluramycin family of drugs. The basic difference between members of this family are the substituent groups present at the different R-positions. The R_5 substituent interacts with the major groove of DNA and the R_8 and R_{10} substituents interact with the minor groove of DNA. Hedamycin has a hydrogen at the R_5 position and bulky sugar groups at the R_8 and R_{10} positions. For altromycin B, the hydrogen is present at the R_8 position and there are sugar groups at the R_5 and R_{10} positions. The E_2 is the epoxide that alkylates the N^7 of guanine.

For the top strand of the DNA-TBP complex of the Adeno-Virus Major Late Promoter (AdMLP-54mer), hedamycin showed enhanced modification of the third guanine, after the second phenylalanine insertion site of TBP. Hedamycin also showed a decreased enhancement of the second guanine, after the second insertion site of TBP on the top strand and a decreased enhancement of the guanine upstream of the first insertion site on the bottom strand.

The DNA-TBP complex for the top strand of the Human Myoglobin Promoter (HmP-64mer) showed enhancement of the CG base-step, after the second phenylalanine insertion site of the top strand of the HmP-64mer, after treatment with hedamycin. This guanine is in the same position as the enhanced guanine in the AdMLP-54mer. Both are the third base downstream of the insertion site on the top strand. There was also decreased enhancement of the guanines on the top strand, immediately upstream of the first insertion site.

For the modification due to altromycin B, the same guanine that was modified by hedamycin in both the AdMLP-54mer and the HmP-64mer was modified by altromycin B as well. The difference between them was that the top strand guanine was modified to a much lesser degree in the HmP-64mer than in the AdMLP-54mer. The top strand of the HmP-54mer also showed a reduction in enhancement of the two guanines upstream of the first phenylalanine insertion site after treatment with altromycin B. This is the same result that was achieved after treatment with hedamycin.

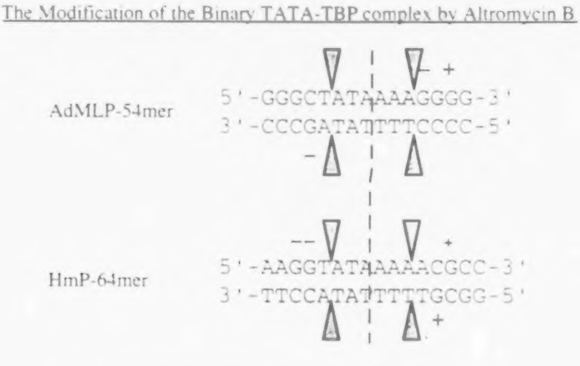


The Modification of the Binary TATA-TBP complex by Hedamycin

-Wedges indicate phenylalanine insertion sites.
-Plus and minus signs indicate a change in the level of modification.
-Dashed line indicates plane of symmetry.

Figure 2: Modification of the AdMLP-54mer and HmP-64mer by Hedamycin

The result that stands out though, is that there was a large increase in enhancement of the bottom strand guanine, immediately downstream of the insertion site, after treatment with altromycin B. After treatment with hedamycin this guanine showed a reduced enhancement, but with altromycin B there is an increase in modification. This increase was much greater than that for the top strand guanine. The difference in the levels of modification by altromycin B, between the top and bottom strand, suggests that there is a preference for alkylation of the bottom strand as opposed to the top strand.



The Modification of the Binary TATA-TBP complex by Altromycin B

-Wedges indicate phenylalanine insertion sites.
-Plus and minus signs indicate a change in the level of modification.
-Dashed line indicates plane of symmetry.

Figure 3: Modification of the AdMLP-54mer and HmP-64mer by Altromycin B

All these results suggest site -specific modification of DNA by pluramycins (review 7). This site is centered around the second base-step, downstream of the second phenylalanine insertion site. This change is caused by TBP binding, which results in a change in the DNA conformation. This change can be visualized using the pluramycin family of drugs.

BEST COPY AVAILABLE

DISCUSSION:

From these results we propose that there is an asymmetric effect induced in the DNA helix as a result of TBP binding. This conformational change occurs at the second base-step downstream of the 3' phenylalanine insertion site. This was confirmed using the family of intercalating-DNA-alkylating drugs known as pluramycins. What we saw was that the asymmetric modification of the sequence was a result of conformational changes induced in DNA. Despite different flanking sequences, different drugs and different TATA promoters there was an area of conformational change at the second base step downstream of the second phenylalanine insertion site that was not present upstream of the TATA site (refer to Figures 1 and 2).

The reason for this asymmetric conformational change in DNA could be due to the nature of the second half of the TATA sequence. Alternating TA's, which are present in the first half of the sequence, are much more flexible than a rigid A-tract. Insertion of a pair of phenylalanines distorts the helix, but this distortion is contained within this flexible alternating TA sequence.

In contrast, the second half of the sequence is made up of a rigid A-tract. This A-tract is not as flexible due to the close proximity of the thymine methyl groups. The fact that the thymines are next to each other result in the methyl groups having steric interactions with each other and the phosphate backbone (9). As a result, the distortion forced into the helix is propagated downstream of the TATA-sequence. The resulting change in the helix can then be visualized using pluramycins. As a result we see a patterns which suggests unwinding in the DNA helix, downstream of the TATA-site. The patterns were similar despite different flanking sequences and varying substituent groups. Of course this is a hypothesis and further tests must be performed to either confirm or deny its validity.

Although, the patterns of modification were similar for the same sequence, there were slight differences. This is partially due to the dependency of the drugs upon the sequence. The strand that was modified was dependent upon the flanking sequences. The reason is largely due to the sugar substituents of each drug. The interaction of the sugars at the R_8 and R_{10} positions with the minor groove, dictate the pattern of modification. Steric interactions with the phosphate backbone cause one strand to be modified as opposed to the other. So the presence or absence of sugars in these positions can lead to preferential modification of one strand over another.

This is exemplified by the modification of the HmP-64mer by altromycin B and hedamycin. The same guanine on the top strand is modified by both drugs, although altromycin B enhancement is not as pronounced (refer to Figures 2 and 3). But the guanine on the bottom strand show a decrease in modification by hedamycin, and an increase in modification by altromycin B. This is because the sugars of hedamycin interact with the phosphate backbone, precluding modification of the bottom strand. Modification of the top strand does not result in such steric interactions, and as a result there is an increase in enhancement.

On the other hand, the bulky sugar groups of altromycin B interact with the phosphate backbone when the top strand guanine is modified. Admittedly the steric interactions are not so inhibitory as to prevent modification, but they do decrease the level of enhancement to a great degree. But we see a large increase in modification of the bottom strand guanine. This is because when altromycin B moves in to modify the bottom strand, the sugar substituents fall with in the minor groove. There are no detrimental steric interactions to prevent modification. As a result we see a preferential modification of the bottom strand as opposed to the top strand.

All these results provide a starting point from which we can describe the DNA-drug cavity induced in DNA by TBP binding. Molecular modeling of the cavity will provide more information on the structural pattern of the unwinding site and how pluramycins interact with it. In addition, these results also provide a starting point from which studies on how the symmetric TBP molecule initiates asymmetric transcription.

Dr. James R. Walker

DNA polymerase III holoenzyme, the primary replication enzyme in *Salmonella typhimurium* and *Escherichia coli*, is composed of two dimeric subunits: a core dimer for polymerization and proofreading, and a β clamp dimer for enhancing the holoenzyme's processivity. Monomeric components of the β clamp are encoded by the *dnaN* gene, and assemble around the DNA strand in a process known as β clamping. One of the products of the *dnaX* gene, the γ subunit, joins four other subunits to form the γ complex that is responsible for β clamping. In order to fully understand the role of the γ complex in β clamping, we attempted to identify potential interacting domains of β with the γ subunit. The approach used was the characterization of a previously mutagenized region that contains *dnaN*, and its upstream gene, *dnaA*. This region has been shown to suppress a temperature sensitive (Ts) defect in the *dnaX* gene of *S. typhimurium* (4), which suggests that the product of one of its two genes interacts with the mutant *dnaX* product. The results verify that the mutagenized region suppresses the defect in the *dnaX* gene. In addition, it was observed that the region fails to suppress when the *dnaA* gene is deleted. These findings indicate that *dnaA* is the *dnaX* (Ts) suppressor, and suggest that the *dnaA* product, besides its function as the initiator of DNA replication, might also be involved in DNA polymerization.

INTRODUCTION

DNA replication in *E. coli* and *S. typhimurium* begins when DnaA, the replication initiation protein, binds, unwinds, and recruits polymerization enzymes to the replication origin. Elongation then occurs in a bi-directional and primer dependent manner (5). DNA polymerase III holoenzyme is the the primary replication enzyme in *E. coli* and *S. typhimurium* that elongates the replication forks. This holoenzyme is composed of two dimeric subunits: a core dimer for polymerization and proofreading, and a β clamp dimer for enhancing the processivity of the core (1, 10).

The assembly of the DNA polymerase III holoenzyme onto the DNA-primer template begins when the β clamp dimer is assembled by the γ complex, a protein composed of the subunits γ, δ, δ',ψ, and χ. This reaction is followed by the loading of the core dimer. Although clues exist as to how the core dimer binds to DNA, the mechanism of β clamping is almost

BEST COPY AVAILABLE

entirely unknown (9). In order to elucidate the mechanism by which the γ complex loads the β clamp dimer, we attempted to identify potential interaction domains between the β clamp dimer and the γ subunit.

APPROACH

Allele specific extragenic suppression was used to identify an interaction domain between the γ subunit and the β clamp dimer. This type of suppression occurs when a non-lethal site specific mutation on one gene suppresses a conditional-lethal site specific mutation of another gene (6). Direct interaction between the mutant sites of the gene products is the most likely explanation for suppression, and implies that the wild type proteins also interact at the same domains (7,8,13).

A previous laboratory (4) located an extragenic suppressor of an *S. typhimurium* temperature sensitive (Ts) *dnaX* gene in the region that contains the *dnaA* and *dnaN* genes. This finding is useful because *dnaN* encodes the β clamp monomer (9), and *dnaX* encodes the γ subunit (3). Hence, in order to find an interaction domain between the β clamp dimer and the γ subunit, this region was further characterized.

The results of the experiments verified that the mutagenized *dnaA-dnaN* region suppresses *dnaX* (Ts). In addition, it was observed that when *dnaA* is absent from the region, suppression is lost. These findings suggest that *dnaA* is the suppressor of *dnaX* (Ts).

MATERIALS AND METHODS

All the bacterial strains and plasmids used in this experiment were provided by Engstrom *et al.* (4), and are described in detail in Tables 1 and 2 respectively. The growth media used are described in Table 3.

Strain	Relevant Genotype	References
RM 212 *S.typhimurium*	*dnaX* (Ts)	4
DB4894 *E. coli*	*dnaN* (Ts)	4
E 177 *E. coli*	*dnaA* (Ts)	14

Table 1: Bacterial Strains

Plasmid	Origin	Cloned Fragment	References
PFF20	PUC 8	*dnaA-dnaN* (Suppressor)	4
PFF52	PUC 8	*dnaA-dnaN* (Wildtype)	4
PFF42	PUC 8	*dnaN* (Suppressor)	4
PFF48	PUC 8	*dnaN* (Wildtype)	4
PUC 18	N/A	N/A	15

Table 2: Plasmids

Medium	Composition
Yeast Extract Tryptone (YET) Broth	0.5% yeast extract, 1% tryptone, and 0.5% NaCl.
YET Ampicillin Broth	YET Broth with 200 µg/ml of ampicillin.
YET Plates	0.5% yeast extract, 1% tryptone, 1.5% agar, and 0.5% NaCl.
YET Ampicillin Plates	YET Plates with 200 µg/ml of ampicillin.

Table 3: Growth Media

The methods described by Maniatis *et al.* (11), and O'Callagan *et al.* (12) were used to transform *E. coli* and *S. typhimurium* strains respectively. Each of the plasmids were transformed into *E. coli dnaA* (Ts), *dnaN* (Ts) and *S. typhimurium dnaX* (Ts) strains. After the transformants were purified three times, their ability to restore the growth of their temperature sensitive defects at the non-permissive temperature of 39 ℃ was checked. It was reasoned that if a plasmid restored the growth of a *dnaN* (Ts) strain, then its cloned fragment contained a functional *dnaN* gene. Likewise, if a plasmid restored the growth of a *dnaA* (Ts) strain, it was reasoned that its fragment contained a funtional *dnaA* gene. Finally, if a plasmid restored the growth .of a *dnaX* (Ts) strain, it was reasoned that its fragment had suppression activity.

Growth restoration of the transformants was checked by the efficiency of plating (EOP) method. This method quantitatively compares the amount of growth at the non-permissive temperature with the amount of growth at the permissive temperature (30 °C) to determine growth restoration.

The EOP method was used by growing the purified transformants in YET Ampicillin broths to an absorbance of 1-1.5. The cells were then serially diluted, plated on YET Ampicillin plates, and incubated for 24-36 hours at 30 °C and 39 °C. Next, the colony forming units per 1 ml of broth (CFU/ml) plated on each plate was calculated by the following formula:

$$\text{CFU/ml: } \frac{[\text{ Number of colonies }]}{[\text{Dilution factor}]\ [\text{ml plated}]}$$

Finally, the EOP was calculated by the following formula:

$$\text{EOP: } \frac{[\text{ CFU/ml at } 39\ ^\circ\text{C}]}{[\text{ CFU/ml at} 30^\circ\text{C }]}$$

RESULTS

As summarized in Table 4, the results verify that the supressor region with *dnaA* and *dnaN* suppresses *dnaX* (Ts). The results also indicate that when the *dnaA* gene is absent from the region, suppression is eliminated.

The suppressor region with *dnaA* and *dnaN* suppresses *dnaX* (Ts) because the plasmid with that region (PFF20) had a much higher *dnaX* (Ts) EOP than the plasmid with the non-supressor *dnaA-dnaN* region (PFF52).

In addition, the PFF20 plasmid had a higher *dnaX* (Ts) EOP than the uncloned plasmid (PUC 18).

Suppression is lost when *dnaA* is absent from the suppressor region because the plasmid with the suppressor region that lacked *dnaA* (PFF42) had a very low *dnaX* (Ts) EOP. This *dnaX* (Ts) EOP was as low as the negative control EOPs of the plasmid with wildtype *dnaN* (PFF48), and PUC 18.

PLASMID	*Cloned Fragment* (Origin)	*E. coli dnaN (Ts)*	*E. coli dnaA (Ts)*	*S. typhimurium dnaX* (Ts)
PFF52	*dnaA-dnaN* (Wild type)	+	+	-
PFF20	*dnaA-dnaN* (Suppressor)	+	+	+
PFF42	*dnaN* (Suppressor)	+	-	-
PFF48	*dnaN* *(Wild type)*	+	-	-
PUC 18	*NONE*	-	-	-

Table 4: Summary of experiments

CONCLUSION

In summary, this study characterized an extragenic suppressor of *dnaX* (Ts) that was located in the *dnaA-dnaN* gene region. Results indicate that extragenic suppression occurs when *dnaA* and *dnaN* from the region are present, but not when *dnaA* is absent.

From these data, we propose that *dnaA* is the suppressor, and suggest an additional role of the DNA replication initiation protein in elongation.

Currently, work is under way to separate *dnaA* from the *dnaX* (Ts) suppressor region and test its suppression activity. Further studies of this suppressor region should promise new insights into DNA replication.

ACKNOWLEDGEMENTS

I thank Dr. James R. Walker for his patience, support and guidance. My appreciations also go to Dr. Alexandra Blinkova for her friendship and advice, Edwin-Gines Candelaria for his suggestions on preparing this paper, and Dr. Russel A. Maurer for providing the bacterial strains and plasmids that were used in this study. Finally, I thank my parents and brother for their unconditional love and support. This work was funded by the University of Texas at Austin's Office of the Vice-President for Research.

Rob Young

Research on sharks has provided significant insights into the struggle against human disease. These studies may reveal how its distinct immune system works through studies of its genetic makeup. Identification of genes conserved throughout evolution may help in the discovery of new ways to battle cancers by determining how potentially lethal genes are conserved in divergent organisms. Three proto-oncogenes (SCL, MLL, CBFβ), two tumor suppressor (p53 and Rb), and two V-D-J recombinase genes (RAG-1 and RAG-2) were radiolabled and used as probes to identify conserved sequences in *Mustelus canis*, the smooth dogfish. All of the proto-oncogenes were conserved while other genes were not found to be conserved at a nucleotide level in the shark. Sharks have existed relatively unchanged for 450 million years. One of the keys to its disease resistance and survival may lie in the genetic makeup and how these genes function.

INTRODUCTION

Certain genes which are associated with basic biological functions have remained intact throughout the evolutionary process. The amount of genetic variance among homologous sequences in different species depends on how long ago the two shared a common ancestor (O'Brien and Clegg, 1993). Only recently has genome evolution become traceable by gene mapping and the identification of relic vestigial sequences, recombination sites, and repeats. Molecular evolution of virus sequences implies cross-species development of viral pathogens. Elasmobranchs (sharks, rays and skates), are phylogenetic descendants of placoderms. The elasmobranch immune system has probably changed little since their appearance 450 million years ago. This may give some insight to a defined, distant but extraordinary period in evolution (Litman, 1996).

It has been speculated that sharks do not get cancer. However, the Smithsonian Institute has records of at least 20 known cases of cancer in sharks (Beardsley, 1993). Despite this observation, it remains possible that development of malignancies may be less common in sharks than in mammals. Data describing malignancies in sharks are not yet well defined and a study of proto-oncogenes, tumor suppressor genes, and V(D)J recombinase genes conserved through evolution may give more insight to the shark's genetic pre-disposition toward cancer.

Immunity in sharks is different from later organisms such as frogs, monkeys, and humans. The ancient immune system of sharks may be as effective if not more effective than that of their more modern counterparts. In the 1980s the horned shark was the first to have genes isolated that encode for immunoglobulins. Studies thus far show, like all homologues for the immunoglobulin genes the shark's also undergoes rearrangement, yet the organization of gene segments within the shark genome differs greatly from that of mammals (Litman, 1996). Sharks have endured exposure to many detrimental infections. Their ability to thwart off these potentially life threatening diseases may be why they have survived for 450 million years. Certain proto-oncogenes (SCL, MLL, CBFβ), tumor suppressor genes (p53, Rb), and V(D)J recombinase genes (RAG-1, RAG-2) are known to be conserved throughout evolution in organisms ranging from chickens to mice to humans.

Proto-oncogenes can be defined as normal cellular genes, which when dysregulated, are associated with malignant transformation. The normal functions of these genes are often crucial for the development and growth of the organism. SCL, MLL, and CBFβ are all proto-oncogenes identified by virtue of their disruption and activation by chromosomal translocation in human leukemias. All these human genes have sequences that are conserved in mouse and *Drosophila* genomes, suggesting that they supply some necessary function for the organism. However, when dysregulated and dysrupted by chromosomal translocation, they are associated with malignant transformation.

The tumor suppressor gene p53 is inactivated in approximately half of all human cancers (Cho et. al., 1994). This gene is part of a pathway that is responsible for damage repair in DNA; this function helps protect genomic balance (Friend, 1994). The Rb gene is a tumor suppressor gene first identified due to its disruption in human retinoblastomas. Since then, this gene has been shown to be an important regulator of morphogenesis and mammalian cell growth; its function clearly is more widespread than simply within the developing retina (Bernards et. al., 1989). Human Rb homologues have been detected in brook lamprey, cat-shark, swordtail, chicken and mouse. Fragments of this gene seem to be present to some degree in genomes of all chordates (Bernards et. al., 1989).

The generation of diverse T cell receptors and immunoglobulins is in large part due to recombination of discrete V (variable), D (diversity) and J (joining) segments in the lymphocyte genome. One of the genes whose product mediates V(D)J recombination, the recombination activity gene (RAG-1), has been found to be conserved to some degree in chickens, frogs, rabbits, horses, goats, dogs, and mice(Schatz et. al., 1989).

This paper uses cross-species hybridization to determine if three representative proto-oncogenes (SCL, MLL, CBFβ), two tumor suppressor genes (p53 and Rb), and the V(D)J recombinase genes (RAG-1 and RAG-2) are conserved in the elasmobranch *Mustelus canis*, commonly known as the Smooth Dogfish. By determining if some of these vital genes are conserved in the shark, this information will enhance the genetic library of one of the oldest classes of vertebrates on the planet. Furthermore, studying how and to what degree these genes are expressed may show the ways different organisms fight cancer.

METHODS AND MATERIALS

DNA from the urogenital, heart, gills, liver and spleen tissue of *M. canis* was extracted using a standard DNA salting out technique. The cells were pelleted and resuspended in 3 mL lysis buffer (0.2 mol/L NaCl, 20 mmol/L EDTA, 40 mmol/L Tris HCl pH 8.0, 0.5% sodium dodecyl sulfate [SDS], and 20 μL proteinase K) and incubated at 50°C for three hours. RNase A was added to a final concentration of 10 μg/mL and the sample incubated at 37°C for 30 minutes. Saturated NaCl (1.5 ml; > 5 mol/L) was added and the sample centrifuged at 5,000 RPM. The supernatant was aspirated and DNA spooled out of solution after precipitation with 2 vol of ethanol (Aplan 1996).

The Southern blots used 10 μg genomic DNA from *M. canis* (heart and spleen), human and mouse digested with EcoRI size fractionated using an 0.8% agarose gels (Aplan, 1996). The human DNA is from the Jurkat T-cell leukemia cell line and the mouse is from the F4-6 murine erythroleukemia cell line. The probes for SCL, MLL, CBFβ, p53, Rb, RAG-1 and RAG-2 were ^{32}P-labeled using a Prime-It II kit (Stratagene, La Jolla, CA) as per manufacturers instructions (cell lines for probes available upon written request). Each blot had one human, one mouse, and two shark lanes for probing. The washes used in hybridizing the probes to the nitrocellulose filter for the Southern blots were washed at 42°C that results in a 75-85% homology to the human gene.

RESULTS

Conserved sequences can be identified by hybridization of discrete restriction endonuclease fragments to radiolabeled probes derived from cloned genes. The human SCL, MLL, and CBFβ probes hybridized to specific fragments in both mouse and shark genomic DNA, indicating that these gene sequences had been conserved throughout evolution. As expected, the conservation between human and mouse was more obvious than between human and shark for these probes. The MLL probe generated a more intense signal than either the SCL or the CBFβ probe, suggesting that MLL is more highly conserved between human and shark than is SCL or CBFβ. p53, Rb, Rag-1 and RAG-2, did not show evidence of specific cross-hybridization between mammalian and elasmobranch species (Table 1). All these human probes showed specific cross hybridization with mouse genomic DNA that served as an internal positive control.

Table 1: Southern Zoo Blot Autoradiograph Results

GENE	CONSERVED
SCL	positive
MLL	positive
CBFβ	positive
P53	negative
Rb	negative
RAG-1	negative
RAG-2	negative

DISCUSSION

Since the SCL, MLL, and CBFβ are conserved in *M. canis* there are some remaining areas of study that need to be addressed to determine if these genes of interest are expressed similar to their patterns in mammals. Since the proto-oncogenes are found in *M. canis*, the smooth dogfish has the potential to develop cancers associated with these genes should they become dysregulated. In humans these tumors are very detrimental. How these genes are expressed may show how the elasmobranch fights cancer in its body.

The lack of hybridization of the Rb tumor suppressor gene was somewhat surprising. According to Bernards (1989), sharks do have an Rb gene. Inability to detect specific cross hybridization in *M. canis* may be due to one of several possibilities. There may have been differences in hybridization conditions, or differences in the Rb probes employed. Moreover, due to the degenerate nature of the genetic code, it is possible that while Rb is conserved at the amino acid level, it is not well conserved at the nucleic acid level. RAG-1 and RAG-2 also resulted in a lack of hybridization in this study. Litman (1996) shows that sharks have use of V(D)J recombination to fight infection but it is arranged much differently than mammals. The inability to detect RAG-1 and RAG-2 may also be due to the degeneration of the genetic code and the level that these genes

2013

are expressed.

Sharks have an immune system which, at first glance, is organized in a fashion similar to mammals, with discrete V ("variable"), D ("diversity"), and J ("joining") segments. However, more detailed study has indicated that in the shark, each V and D segment is associated with a specific J segment, as opposed to mammalian immunoglobulin loci, where a cluster of 50-100 V segments is located upstream of relatively few D and J segments (Bartl et. al., 1994). Recent research has found all four classes of mammalian T cell antigen receptors in skates. This finding leads to the high probability that they will be found to be conserved in all elasmobranchs. In Elasmobranchs T cell receptors seem to have undergone no tangible evolutionary changes since the shark's divergence from the mammals (Litman, 1996). Until more is known about the shark and how its immune system works and what genes are conserved, its putatively low malignancy rate will still be a mystery.

AN ANALYSIS OF LIPID BILAYER STUDIES OF SINGLE ION CHANNELS USING M2 AS AN EXAMPLE

Erin E. Grimm

Faculty Advisor
Dr. Carl Helrich
The Turner Laboratory
Department of Physics
Goshen College
Goshen, IN 46526

The rapid fluctuations among sets of open and closed states as revealed in the phospholipid bilayer studies of single biological ion channels are key to understanding detailed dynamics of these complex syslems. A progressive analysis of the M2 protein ion channel from influenza A is presented as a model for obtaining insight into these channel dynamics. The Markovian or chaotic character of the system is determined by obtaining carrying capacities and Hausdorff dimensions for the channel current as a time function. By binning the currents (pA) the frequencies of transitions among various channel states are determined. Finally, the kinetics of transitions from these states are obtained. This progressive analysis provides a definitive characterization of single channel dynamics, which is presently being employed in the study of channels common to picornaviruses.

INTRODUCTION

In simplest form the biological ion channel is a hydrophilic pore formed by the linking of a number of membrane spanning alpha helices from one or more membrane proteins [Hille, 1992]. Channels may be spontaneously created and annihilated by the linking and disengaging of such helices resulting in the rapid time variation in channel currents or may possibly be permanent structures with the rapid gating resulting from the dynamics of the ion flow and changes in the protein state [Hille, 1992].

By incorporating proteins, or vesicles containing these proteins into phospholipid bilayers it is possible to study the currents of individual channels under distinct conditions imposed by solutions in the bathing media. The current passing through the channel at a fixed potential impressed across the bilayer is recorded. Bilayer data are gathered on a scale of 0.25 mS and over periods of 1S. In the example considered in this paper data were gathered over 40 such 1S periods at different times.

Figure 1 provides typical results from such an experiment. Channel activity is characterized by a very rapid change in current from one level to another. The channel currents appear in discrete, almost quantum levels with dwelltimes which may be milliseconds. These levels are evidenced in panel B of the figure.

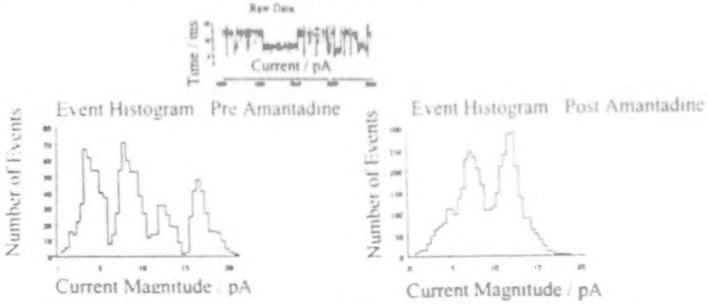

Figure 1. Panel A shows a current versus time trace gathered in a bilayer experiment. The channel activity appears as rapid large transitions among sets of current levels. Panel B provides event histograms, which are plots of the occurrences of a current against the current magnitude, for the three traces: prior to and after exposure to amantadine (see text).

In dynamical character the channel may be Markovian, in which the channel lacks memory and each state change is dependent only on the present state, or chaotic, in which the channel is a nonlinear dynamical system with memory. Because of the role played by channels in biology and because of the desire to pharmacologically combat many viruses whose life cycles depend on such channels, the question of the form of the channel dynamics is of practical importance.

This paper outlines a sequence of steps which have been undertaken to establish the basic character of the channel dynamics using the M_2 protein channel of influenza A, which is blocked by the drug amantadine [Pinto, et al., 1992], as an example. The chaotic nature of the channel dynamics is established through analysis of the time dependence of the channel current under conditions of exposure of the channel to amantadine. A study of the transition frequencies between current levels introduces the concept of a frequency landscape, in which the initial and final levels form a grid in the horizontal plane and the transition frequency is plotted on the vertical axis. The form of this landscape and its variation under different conditions provides insight into the details of channel behavior. For chaotic channels a final step may be undertaken which establishes the fractal dimension for the self-similar dynamics. This provides understanding of the transition pathways out of a given state.

MATERIALS AND METHODS

The data were collected from a single channel from purified M_2 protein prior to and 20 and 50 minutes after exposure to amantadine. The records each consisted of 40,000 mS traces. In the experiments the bilayer membrane consisted of phosphatadylethanolamine and phosphatadylcholine in a ratio of 75:25 and a concentration of 50 mg/ml. The salt solution in the two chambers was Sodium Methane Sulfonate. The data are gathered on time scales which are neither those of the protein nor of the ions, which are to be considered in any molecular understanding of the channel dynamics.

ANALYSIS

The analysis treats only the raw data files for current as a function of time. No curve fitting is involved until the step 4 in the analysis. The first two steps establish the Markovian or chaotic character of the data. The third provides a graphical picture of the transition frequencies among the various current levels. The fourth step is only undertaken if the dynamics prove to be chaotic, as is the case for M_2. This fourth step provides a quantitative description of the transition from a given level in terms of fractal dimension, which may be interpreted in terms of pathways out of the corresponding state.

Step 1 is a box counting procedure [Bassingthwaighte, et al., 1994]. The data are read at times (t), (t+T), ..., (t+nT), where T is a characteristic time for the system and (n+1) is the dimension of the analysis. This produces (n+1) sequences defining (n+1) axes for the representation. The axes are gridded with a grid size r defining cubes of volume r^{n+1}. If N(r,A) is the number of cubes required to cover the data A in the given space, then the carrying capacity is defined as

$$Cap\ A_{n+1} = \limsup_{r \to 0} \frac{\ln N(r,A)}{\ln(1/r)} \tag{1}$$

For chaotic systems equation (1) has a limit as the space dimension increases, but is limitless for Markovian systems, for which the representative points fill all volumes regardless of volume size.

Eckmann and Ruelle [Eckmann and Ruelle, 1985] have pointed out that the Hausdorff dimension is a more reliable quantity for analyzing data. Obtaining a Hausdorff dimension is the second step in the analysis. The data are read at the same times as in the box counting. Each time point, t_j, serves to define a vector of dimension $m = (n+1)$ as

$$X(j) = [I(t_j), I(t_j+1), \ldots, I(t_j+m-1)] \tag{2}$$

for N such vectors the quantity $C_N^m(r)$ is defined as

$$C_N^m(r) = \frac{1}{N^2}\{\ \textit{number of ordered}\ [X(i), X(j)]\ \textit{such that}\ d[X(i), X(j)] \le r\ \} \tag{3}$$

where

$$d[X(i), X(j)] =$$
$$\{(I(i+1) - I(j+1))^2 + (I(i+2) - I(j+2))^2 + \quad \cdots \quad + (I(i+m-1) - I(j+m-1))^2\}^{1/2} \tag{4}$$

is the Cartesian distance between $X(i)$ and $X(j)$. The Hausdorff dimension is then

$$\beta_m = \lim_{m \to \infty} \lim_{r \to 0} \frac{\ln C_N^m(r)}{\ln(r)} \tag{5}$$

Again the existence of the limit in (5) implies a chaotic basis for the data.

Independently of the dynamics, frequencies for transitions among current levels are of interest. These are easily evaluated from the raw data by determining the occurrence of consecutive levels "p" and "q" in the data. This defines frequency of the transition $(p \to q)$. In the landscape the levels p and q form the two axes defining the horizontal plane and the frequency is plotted on the vertical axis. The high values of frequency appear as mountain peaks on the landscape. If the dynamics are Markovian the number of times a particular current level occurs is proportional to the number of configurations of the channel (channel states) that result in that current. This is reflected in the event histogram, which provides directly the number of times a current level appears. In a Markovian system the transition from one state to another is strictly probabilistic so the transition frequencies for a given level should resemble the histogram. Chaotic dynamics would produced a non-symmetric pattern.

Step 4 in the analysis is only undertaken if the steps 1 and 2 indicate that the underlying dynamics are chaotic. Here the analysis is based on time self-similarity characteristic of chaos. The Ansatz is made that at the time (t) the rate at which transitions from a current level α occur is given by

$$\frac{d\rho_\alpha(t)}{dt} = -k_\alpha(t)\rho_\alpha(t) \tag{6}$$

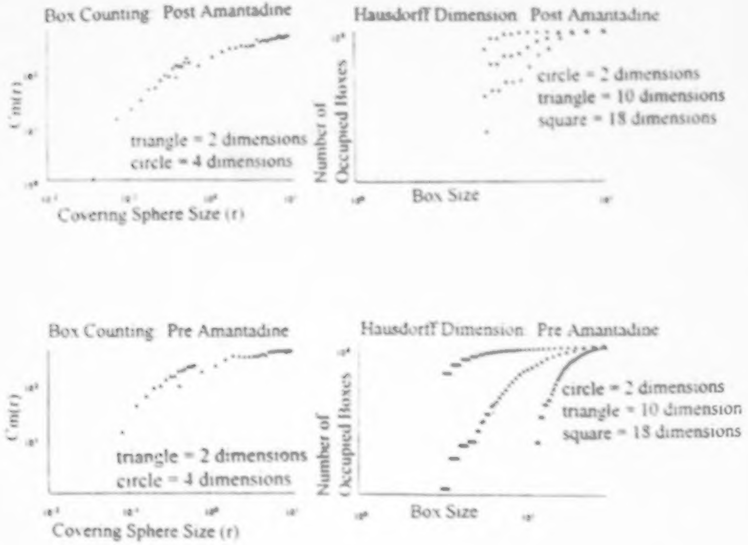
where $\rho_\alpha(t)$ is the number of channels in the membrane containing the channels of interest, in the current state α at the time (t). The rate coefficient, $k_\alpha(t)$, models the nonlinear dynamics of the underlying protein. For time self-similarity $k_\alpha(t)$ has the form

$$k_\alpha(t) = A_\alpha t^{1-D_\alpha} \tag{7}$$

where A_α is a constant and D_α is the fractal dimension for the dynamics. Liebovitch and Toth [Liebovitch and Toth, 1991] have shown that the fractal dimension is a measure of the structure of the pathways for the transition from a given (protein) state. If the protein is in one of the states (say α_p) which result in the current level α and undergoes a transition from that state, then there are a number of other states(say the set $\{\beta_q\}_{q=1}^{N}$) which are possible for the final state producing the next current level β. A transition of the protein $(\alpha_p \to \beta_q)$ is a possible pathway from the state α_p. These pathways have a density which determines the fractal dimension. The procedure to be undertaken to find D_α from the raw data files has been provided elsewhere [Qiao, 1995].

DISCUSSION

In Figure 2 the results of analysis steps 1 and 2 for the M_2 channel prior to and at two stages after the addition of amantadine to the bathing solution



Box Counting: Post Amantadine

Hausdorff Dimension: Post Amantadine

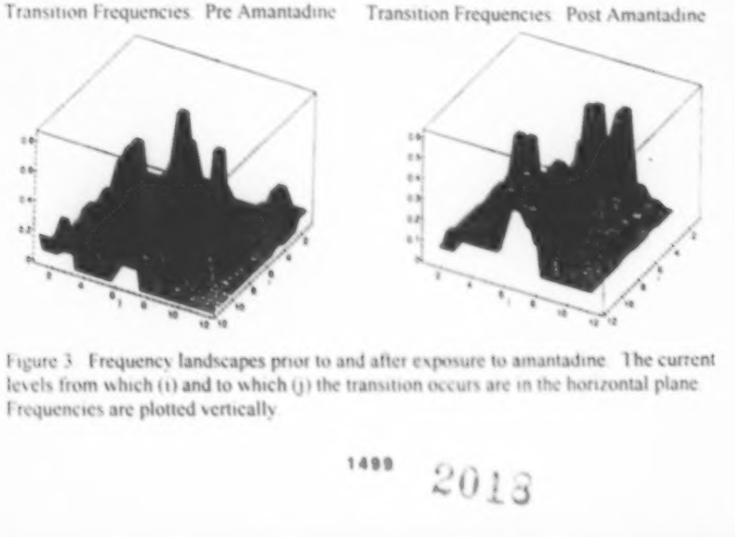
Box Counting: Pre Amantadine

Hausdorff Dimension: Pre Amantadine

Figure 2. Carrying capacity (Panel A)and Hausdorff dimension (Panel B) plots for the M_2 channel prior to and after amantadine exposure

A strong indication of chaotic behavior is evidenced prior to the addition of amantadine while a loss of chaotic structure appears particularly 50 minutes after the addition of amantadine. The event histograms (not shown) reveal that the channel is still active having lost only the top level(s).

The frequency landscapes in Figure 3 indicate a change from a rich and varied structure for the transition frequencies prior to the addition of amantadine to a less varied structure after exposure. That is there are more transition pathways available prior to the addition of amantadine than after.



Transition Frequencies: Pre Amantadine

Transition Frequencies: Post Amantadine

Figure 3. Frequency landscapes prior to and after exposure to amantadine. The current levels from which (i) and to which (j) the transition occurs are in the horizontal plane. Frequencies are plotted vertically.

The plots of Figure 2 establish that the M_2 channel is chaotic, at least prior to the application of amantadine. Therefore, step 4 in the analysis was undertaken for this system. The results are presented in Table 1. In this table the current levels indicated by A, B,.. are defined in the event histograms of Figure 1.

Initial State	Fractal Dimension
Pre Amantadine:	
Top (A)	1.87
Central (C)	1.62
Bottom (D)	1.35
Post Amantadine	
Top (A)	1.45
Bottom (B)	1.45

Based on the ideas of Liebovitch and Toth, the variation in fractal dimension indicated is consistent with the structural change indicated by the landscapes. The landscapes indicate a more limited accessibility as a result of the application of amantadine. After the addition of amantadine, the rich and varied form with many peaks becomes a more limited clustering of peaks. The peaks indicate possible transitions. A decrease in the number of peaks, then, in the language of a density of transition pathways, corresponds to a density with a reduced range, which is consistent with the expectations of Liebovitch and Toth for a decrease in fractal dimension.

The present example of the behavior of the M_2 protein channel has indicated the consistent understanding of the basic character of the dynamics of a very complicated channel system using the procedure proposed. Of course the details remain opaque, as does the actual molecular structure of the channel itself. But such a study of the dynamics based on raw data is a necessary step toward the successful modeling of a channel and a model is necessary for logical design of pharmaceutical approaches to the problems of disease control.

The procedure outlined here is presently being pursued by CSH in the study of the channels of picornaviruses and plant viruses (Southern Bean Mozaic Virus) as well as endogenous channels in the oocytes of *Xenopus Laevis*. These systems reveal multiple states and variation in dynamics under application of acids and antibodies.

Metal Regulated Gene Expression in *Pseudomonas fluorescens*

Marsha L. Kukuk

Department of Biological Sciences

Faculty Advisor
Silvia Rossbach

Heavy metals, which accumulate in the environment, pose a threat to animal and human health. Microorganisms are also affected, and must constantly adapt to these harsh conditions in order to survive. We are interested in identifying genes that are regulated in order for common soil bacteria to facilitate metal tolerance. Utilizing transposon mutagenesis, and the *lacZ* reporter gene, we have identified seventeen *P. fluorescens* ATCC 13525 mutants that express differential gene activity in the presence of cadmium. We have characterized twelve mutant strains that display higher gene activity after metal exposure, whereas five mutant strains showed reduced gene activity. Several mutant strains have shown at least a five-fold increase in gene activity as a result of cadmium exposure. Additionally, several mutant strains have shown similar differential gene expression in the presence of copper or zinc.

INTRODUCTION

As a result of industrial pollution and poor methods of waste disposal, many toxins, including metals, have accumulated in the environment. Once in the soil, heavy metals may contaminate water supplies, including those used for drinking water (Paasivirta, 1991). Subsequently, metals may enter the food chain if they have the ability to accumulate inside organisms. Cadmium, for instance, may enter the environment as a by-product of fertilizers or industrial wastes, or directly through mining processes. Cadmium is also used in rechargeable batteries, pigments, plastics and electroplating (Ron et al, 1992).

Microorganisms must constantly adapt to their external environment to survive in their specific ecological niche. Such adaptations include modifying gene expression to optimize survival opportunities in a harsh environment. While some bacteria have the ability to express metal resistance genes, which are commonly carried on plasmids, others might not contain these plasmids. We would like to understand how common soil bacteria react to elevated levels of toxic metals.

The purpose of this study is to identify genes in *P. fluorescens* ATCC 13525, which are differentially induced or repressed in the presence of cadmium. Once we have identified several genes that show differential expression, identification of their specific function will allow us to determine if these genes indeed aid in metal tolerance. In general, this information may identify mechanisms, that may be used by bacteria to cope with elevated levels of heavy metals. For example, the gene may encode for metal accumulation within the cell, reactions that change the oxidation state of toxic elements, or efflux mechanisms. Eventually, this information will benefit bioremediation efforts that aim at using biological organisms to clean up contaminated sites.

METHODOLOGY

A convenient way to monitor gene expression in bacteria is through a reporter gene system. For our study, the *lacZ* reporter gene, encoding the β-galactosidase enzyme, has been selected. If a transposable element containing the *lacZ* gene is inserted downstream of an active promotor, the level of enzyme activity will represent the gene activity directed by that promotor. *Lac* activity is identifiable as β-galactosidase production through various colorimetric assays. Specifically, we are interested in characterizing genes that are expressed little or none on a control medium, but highly expressed in the presence of cadmium, or vise versa.

Transposon Tn*5*-B20 carries the promotorless *lacZ* reporter gene as well as the *nptII* gene conferring kanamycin resistance (Km^R). Conjugation between donor strain *E. coli* S17-1 [pSUP102/Tn*5*-B20] and recipient strain *P. fluorescens* ATCC 13525 assured the creation of *P. fluorescens* mutants. Since suicide vector pSUP102 cannot replicate outside of *E. coli*, Tn*5* will transpose into the *P. fluorescens* genome and create true mutants. At that point, isolation of *P. fluorescens* Km^R mutants occurred on a medium that counterselected against *E. coli*.

A common colorimetric method used to identify β-galactosidase activity is to grow the bacteria on a medium supplemented with the substrate X-Gal (5-Bromo-4-Chloro-3-indolyl-β-D-galactoside). X-Gal is cleaved by β-galactosidase to yield an indigo precipitate, e.g. the darker the blue, the higher the enzyme activity.

Southern blot analysis and the hybridization experiment were performed according to the procedure specified by the manufacturer, Boehringer Mannheim (Indianapolis, IN). The hybridization probe was labeled using a digoxigenin (DIG) DNA labeling kit. Detection for hybridizing fragments utilized luminescent techniques as specified by the manufacturer.

To quantitatively determine the level of gene activity for each tagged gene, another enzyme assay was used. ONPG (ortho-nitrophenol-β-D-galactoside) is a substrate that is hydrolyzed by β-galactosidase to yield ONP which has a characteristic yellow color. The amount of ONP can be measured readily in a spectrophotometer as the optical density (OD) at a 420 nm wavelength (OD_{420}). Additionally, the culture density of a sample may be measured in a spectrophotometer at a 600 nm wavelength (OD_{600}). Utilizing a protocol from Miller (1989), the enzyme assay was performed with minor modifications. Experimental cultures were grown in rich liquid media overnight either in the presence or absence of cadmium. The enzyme activity was calculated as Miller Units (see equation 1).

$$\text{Miller Units} = \frac{1000 \times OD_{420}}{t \times v \times OD_{600}} \qquad t = \text{reaction time, } v = \text{reaction volume} \qquad (1)$$

RESULTS AND DISCUSSION

Identification of MIC

In order to identify a suitable concentration to screen for genes which are influenced by elevated levels of metal, the minimum inhibitory concentration (MIC) of several metals was identified for *P. fluorescens* ATCC 13525 (see Table 1). The MIC is defined as the "lowest concentration of toxic element which inhibits the formation of colonies" (Mergeay, 1991). Our goal was to select a metal concentration that would challenge bacterial growth, but still allow sufficient growth for experimental purposes. Table 1 shows the results of our experiments establishing the MIC concentrations for different metals.

Table 1. MIC values *P. fluorescens* ATCC 13525 on an agar medium

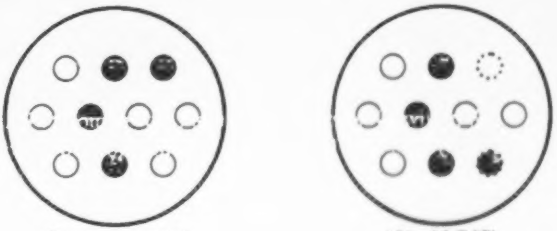
Metal	Medium	Minimum Inhibitory Concentration
$CdCl_2$	rich	200.0 µM
	minimal medium	50.0 µM
$HgCl_2$	rich	5.0 µM
	minimal medium	2.0 µM
$ZnSO_4$	rich	2.0 mM
$CuSO_4$	rich	2.0 mM

Creation of *P. fluorescens* Tn*5*-B20 mutant bank

Using the mutagenesis protocol outlined in methodology, a mutant bank of 5000 *P. fluorescens* strains containing random insertions of Tn*5*-B20 was generated.

Identification of metal-regulated genes

All five-thousand mutant strains were screened on a rich medium containing Km and X-Gal, and parallel plates supplemented with 150 µM $CdCl_2$ (150 µM was selected as a challenging concentration because it is just below the *P. fluorescens* $CdCl_2$ MIC). Figure 1 shows an example of the phenotypic change in color indicating that a mutant colony contained a differentially expressed gene on the metal medium. For example, the colony in the upper right hand corner (top row) shows reduced activity in the presence of cadmium. This change is evident by the change in colony color from dark (blue) on the control medium to light (white) on the medium containing cadmium. The opposite effect is seen for the lower right hand colony (bottom row) which shows an increase in gene activity in the presence of cadmium.



Control, no metal

150 µM $CdCl_2$

Fig 1 Diagram depicting X-Gal screening of *P. fluorescens* Tn*5*-B20 mutants for differential gene expression on rich media supplemented with Km and X-Gal. Colonies on the metal medium show an increase or decrease in gene activity, detectable by a change in color.

Seventeen mutant strains were identified that displayed differential gene activity on the metal medium. Specifically, thirteen mutant strains displayed a higher level of gene expression and four a lower level of gene expression in the presence of $CdCl_2$. Two additional mutants containing either a constitutively expressed or repressed gene were also isolated as positive and negative controls.

Determination of Tn*5*-B20 transposon insertion sites

To prove that the Tn*5*-B20 transpositions were random and single events in each mutant strain, a hybridization experiment was performed. The total chromosomal DNA from the seventeen *P. fluorescens* mutants, and *P. fluorescens* ATCC 13525 (wild type) was digested with *Eco*R1 and separated by agarose gel electrophoresis. The gel was blotted and hybridized with the 2.2-kb *Eco*R1/*Sac*1 DNA fragment of pMC1403 containing the *lacZ* gene, labeled with digoxigenin.

Of the seventeen mutant strains, each contained only one hybridizing fragment clearly visible at a unique location in the chromosome. This observation proved that the transposon insertions were random and single events. Additionally, the wild-type (negative control) showed no hybridizing fragments.

Quantitative determination of metal-regulated gene activity

In order to obtain quantitative values for metal regulated gene expression, we performed the β-Galactosidase enzyme assay. Figure 2 shows the results obtained for the seventeen mutant strains, plus two control mutants, in the presence of 75 µM $CdCl_2$.

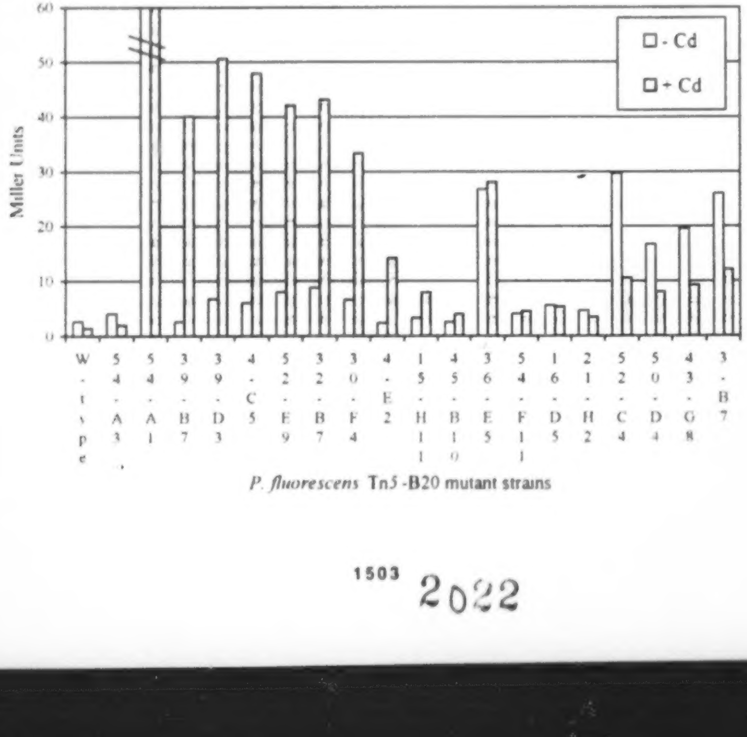


Fig 2 (previous page) β-galactosidase activity (expressed as Miller Units) of *P. fluorescens* Tn5-B20 mutant strains in the presence and absence of 75 μM $CdCl_2$

Several mutant strains show a significant increase or decrease in the presence of cadmium The negative control, mutant 54-A3, did not exhibit a high level of gene expression The positive control, 54-A1, on the other hand had enzyme activity that went off the graph (actual ~877 units) The gene activity of mutant strain 39-B7 was approximately 20 times higher in the presence of cadmium Other mutant strains, 32-B7, 39-D3, 4-C5, 52-E9, 30-F4 and 4-E2 had gene expression at least five times higher when grown in cadmium than without the metal

Four mutant strains, those furthest to the right on the graph, showed a distinct decrease in gene activity when grown in a medium containing cadmium These four mutants, 52-C4, 50-D4, 43-G8 and 3-B7, indicate that the tagged gene is repressed in the presence of metal Other colonies (36-E5, 54-F11, 16-D5, 21-H2) did not show a significant change in gene expression, if any, at a concentration of 75 μM cadmium

Response of mutant strains to copper and zinc

In order to determine if the mutant strains contain a gene that may be differentially expressed in the presence of other metals, each mutant was screened on media supplemented with copper or zinc For both metals, a 1 mM concentration was selected (just lower than the predetermined MIC, table 1)

On the medium containing $ZnSO_4$, seven mutants were identified that displayed differential activity similar as on the medium containing cadmium, three were induced, and four were repressed On the medium containing $CuSO_4$, six mutants were identified that displayed differential gene activity similar as on the medium containing cadmium, two were induced, and four were repressed as a result of metal exposure It is important to note that the same four mutants were repressed on all three metal mediums

Phenotypic growth experiment

It is important to point out that the tagged gene of each exconjugant is mutated as a result of the Tn5-B20 insertion Thus, if a gene is actually involved in metal tolerance, the mutant should show a decreased ability to grow in the presence of cadmium In order to determine the phenotype of the mutant strains, each mutant was grown in the presence and absence of cadmium in full liquid media The specific growth rate of each mutant strain was determined and compared to the growth rate of the *P. fluorescens* wild type Specifically, only one mutant, 45-B10, showed a significant decrease in growth rate when compared to the wild-type control in a medium containing 150 μM $CdCl_2$ (Fig 3)

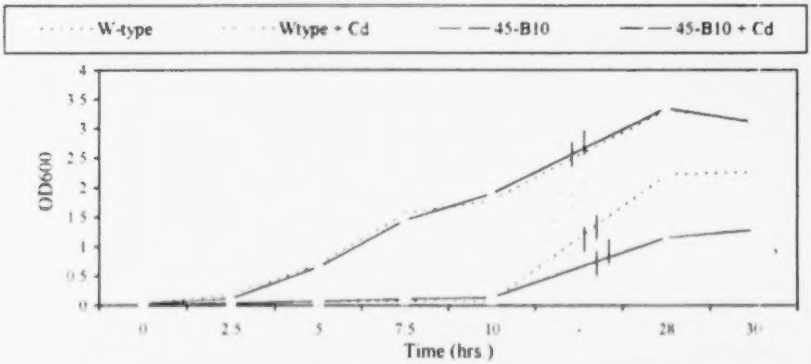

Fig 3 Graph comparing the growth rate of *P. fluorescens* mutant strain 45-B20 and *P. fluorescens* ATCC 13525 wild type in rich media supplemented with 150 μM $CdCl_2$

CONCLUSION

We have succeeded in identifying seventeen *P. fluorescens* Tn5-B20 mutant strains containing genes that were differentially expressed in the presence of cadmium Several of these mutants also showed differential gene activity in the presence of either copper or zinc Finally, one mutant strain showed a significant decrease in the ability to grow in the presence of cadmium when compared to the wild-type strain

Cloning and sequencing of the tagged gene from each of the seventeen *P. fluorescens* mutant strains will further elucidate the possible role and function of these genes By comparing the gene sequences to public databases, homologous sequences may be identified and provide a hint on the role of each gene responding to metal exposure This information will be helpful in understanding the adaptations a common soil bacterium may undergo as a result of heavy metal stress

The Development of a PCR-Based Test to Identify the Red Factor Coat Color Genotype in Horses by RFLP Analysis

Staci Murguia

Veterinary Genetics Laboratory
University of California at Davis
Davis, CA 95616

Faculty Advisor:

Ann T. Bowling

A PCR-RFLP test (polymerase chain reaction-restriction fragment length polymorphism) was conducted on hair samples from 371 horses and serum samples from 31 horses to investigate the robustness of a DNA-based test to diagnose the red factor coat color allele (*e*) at the extension (*E*) locus. DNA from the serum and extracted hair roots was amplified by PCR. After DNA amplification, the samples were digested with Taq I and analyzed by gel electrophoresis to detect the mutation. Our data were matched with the color reported to us for each horse and confirmed that the PCR-RFLP based protocol appears to be a good candidate test for diagnosing the presence of the recessively inherited coat color in horses. Each horse breed was in Hardy-Weinberg equilibrium for this gene, with the frequency of the E allele being .30 for Paints, .28 for Quarter Horses, and .42 for Miniature Horses.

BACKGROUND

For breeders of many domestic animals, coat color is an important characteristic that often contributes significantly to the value of the animal. An ability to predict what coat colors will result from particular breedings would be an invaluable tool for breeders. Although control of coat color is multilocus, an animal's ability to produce black pigment can be traced back to a single locus of control, the MSHR gene (MC1R). A missense mutation of a thymine to a cytosine in the coding sequence leads to a dysfunctional MSHR, thus a horse lacking the ability to produce black pigment may result in a chestnut coat color due to the synthesis of the red/yellow pigment phaeomelanin.

The chestnut coat color is a predominant color variant in horses. It is inherited in a simple Mendelian fashion with the phenotype characteristic of an entire red coat that lacks both brown and black pigmentation. It is the extension locus (*E*) along with the agouti (*A*) locus that controls the amount of phaeomelanin and eumelanin produced. Data show that the chestnut color is controlled by the bottom recessive allele (*e*) at the (*E*) extension coat color locus. The extension locus encodes the melanocyte-stimulating hormone receptor (MSHR). Animals with functional MSH receptors are able to receive the melanocyte stimulating hormone (MSH) which induces a switch from the production of phaeomelanin to eumelanin. Once a mutation occurs at the extension locus, the production of phaeomelanin remains constant due to a dysfunctional MSH receptor that can no longer switch to synthesize eumelanin. Since the expression of MSHR is dominant, it is denoted with an (*E*) where as the recessive mutant type is denoted by (*e*). As is characteristic of Mendelian inheritance, red coat color is phenotypically seen only when the genotype is homozygous (*ee*). (Marklund et al., 1996)

MATERIALS AND METHODS

Three sets of primers were used to determine the genotypes of 371 domestic horses (Paints, Quarter Horses, and Miniature Horses) and 31 Przewalski's horses DNA and serum samples from these animals were provided by the Veterinary Genetics Lab. PCR was carried out in 25 ul reactions containing 2.5 ul of 10X buffer (Promega), 1.5 mM $MgCl_2$, 0.15 mM each dNTP, 10 pmol of each primer and 1 U Taq polymerase (Promega). PCR was performed on M J Research PTC-100 with a 10 minute- 95°C "hot start" at which time our master mixes were added to the samples. This step is followed by 95°C- 60 sec., 34 cycles of 94°C- 60 sec., 62°C- 30 sec., 72°C- 45 sec., and 72°C- 10 min. After amplification, the PCR products were digested for two hours at 65°C with 10 U Taq 1 (Promega) followed by a gel electrophoresis in which 5-

BEST COPY AVAILABLE

15 ul of the digested PCR product was added to each well on a 1.6% or 3.0% agarose gel run at 80 volts for 2-4 hours.

RESULTS

Data collected from the 371 DNA samples and 31 serum samples are represented in the charts below.

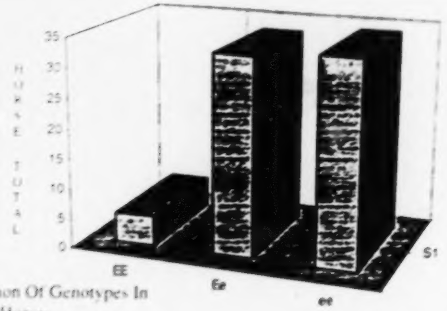

Figure 1: Distribution Of Genotypes In Paint Horses

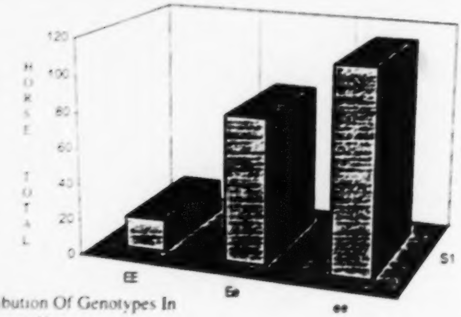

Figure 2: Distribution Of Genotypes In Quarter Horses

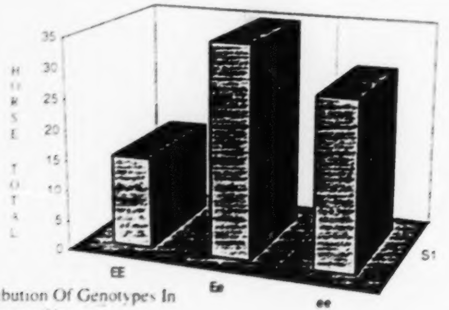

Figure 3: Distribution Of Genotypes In Miniature Horses

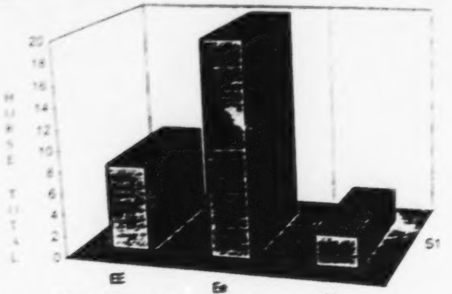

Figure 4: Distribution Of Genotypes In Przewalski's Horses

DISCUSSION

The data accumulated through the hair and serum samples were accurate in correlating the genotype of the horse to its phenotype. Results obtained were consistent with color information provided. All chestnuts, sorrels, palomino's, and red duns typed as (*ee*). All horses with a black phenotype (black, bay, brown) typed as (*E*) or (*Ee*). All three primer sets provided the same results. The most efficient, specific and easiest to read was primer set 3. There seemed to be fewer non-specific bands and a sharper product compared to the results when either primer set 1 or 2 was used. The Hardy-Weinberg equilibrium equation was used to establish the frequency of the (*E*) allele in the horse populations. The following results of .30 for Paints, .28 for Quarter Horses, and .42 in Miniature Horses established that the observed phenotypes correlated to the frequency expected in a random mating population. In Przewalski's horses the frequency of the (*E*) allele (.58) was not in Hardy-Weinberg equilibrium, probably due to a small sample size.

Differentiation and Classification of *Bdellovibrio bacteriovorus* using Random Amplified Polymorphic DNA (RAPD) Analysis

Bao-Dan T. Nguyen

Department of Biology

Saint Joseph's University
5600 City Line Avenue
Philadelphia, PA 19151

Faculty Advisor

Dr. John J. Tudor

Polymerase chain reaction (PCR)-based methodology, entailing random amplified polymorphic DNA (RAPD) analysis was used to assess the genetic similarities and differences among 16 different *Bdellovibrio* strains. Bdellovibrios are gram negative predatory bacteria on which there is little taxonomic information. Genomic DNA from prey-independent strains was isolated using the boiling method of Mazurier, et al. (1992). Four 10 base primers were determined to produce distinct amplification products for the bdellovibrios tested. The banding patterns of the different strains illustrated a common ancestry among the strains as well as a distinction between strains. These results suggest that the RAPD technique of generating DNA fingerprints could be used as a valuable tool for the rapid and inexpensive identification of *Bdellovibrio* isolates.

INTRODUCTION

Bdellovibrio bacteriovorus is a gram negative predatory bacterium. Its life cycle consists of an attack phase and a growth phase. The attack phase is characterized by attachment to and penetration of the outer layer of the prey cell. The growth phase is initiated following penetration, whereby the attacked cell is transformed into a spherical bdelloplast in which the *Bdellovibrio* elongates. Eventually, lysis of the prey cell leads to release of the progeny bdellovibrios.

Bdellovibrios are ubiquitous, existing in freshwater, sewage, and marine habitats. They exhibit phenotypic similarities but are genetically diverse. The current classification is inadequate and relies only on the biochemical and morphological characteristics and neglects the genetic diversity of bdellovibrios.

Genetic similarities and differences of distinct bacterial strains can be detected by Random Amplified Polymorphic DNA (RAPD) analysis (Welsh and McClelland, 1990). This method is based on the use of single arbitrary primers in a polymerase chain reaction (PCR) of low stringency to amplify segments of the genomic DNA. The primer is mixed with genomic DNA in the presence of a thermostable DNA polymerase, and then subjected to temperature cycling conditions. The resulting amplified fragments function as polymorphisms for DNA fingerprinting. RAPD markers have been used successfully to identify strains of various bacterial genera, such as *Camplyobacteria* (Mazurier,et al., 1992), *Haemophilus* (Myers,et al.,1993), *Streptococcus* and *Lactococcus* (Cancilla, et al.,1992). The pattern of the amplified sequences obtained is primer and strain specific, with different strains generating different amplification products which can be visualized in agarose gels. Amplification reactions are repeated using several different primers.

MATERIALS AND METHODS

Bacterial Strains

The following prey independent *B. bacteriovorus* strains were used: 109JA, 109D, Xty, Sa109, 110, 114, 100, E, 120, SaD3, Xpf2, UKi1, UKi2, WJ, 2484, A3.12.

DNA Preparation and Isolation

Nine milliliters of peptone yeast extract (PYE) were inoculated with 1 milliliter of the desired *Bdellovibrio* strain and incubated at 30°C with shaking overnight. The culture was centrifuged (12,000 rpm for 10 min.) and the pellet was washed in saline solution, then pelleted by centrifugation. The supernatant was discarded and the cells were suspended in one milliliter of sterile distilled water. The cell suspensions were then incubated for 10 minutes in a boiling water bath and then centrifuged at 12,000 rpm for 5 min. (Mazurier,et al., 1992). The supernatant was adjusted to an O.D $_{260}$ of 0.15 in sterile distilled water.

Amplification Conditions

Amplification reactions using random primers were accomplished in a reaction mixture (final volume ~ 25 μl) containing: 10 μM Tris-HCl, pH 8.3, 50 μM KCl, 3.0 μM MgCl$_2$, 200 μM each of dATP, dCTP, dGTP, dTTP, 1.0 μM of a single 10-mer, 5units/100 ml of Taq DNA polymerase, < 1mg/100 ml genomic DNA. Four primers with the following sequences were determined to produce distinct amplification products for the bdellovibrios tested: TGCCGAGCTG (OPA2), AGTCAGCCAC (OPA3), AATCGGGCTG (OPA4), AGGGGTCTTG (OPA5) obtained from Operon Inc.

Amplification was carried out in a thermal cycler programmed for 1 cycle for 2 min. at 94°C, followed by 30 sec. at 38°C, 30 sec. at 72°C, and 30 sec. at 94°C, followed by 45 cycles of 30 sec. each at 94°C, 38°C, and 72°C.

The amplification products were separated by gel electrophoresis in 1.8 % Metaphor agarose gels with 1/2 X TAE buffer at 150 volts for 1.5 hours. Banding patterns were visualized by an ultraviolet transilluminator after ethidium bromide staining. A 50-1000 bp DNA ladder (FMC) was used as the size marker. Gels were documented using a Stratagene Eagle Eye II Gel Documentation System equipped with a CCD video camera.

Analysis

The banding patterns were analyzed using Scanalytics RFLP Scan software to generate PAUP reports. The output from this program was utilized to construct dendrograms from TREECON software. (Van de Peer, De Wachter, 1994)

RESULTS

A total of twenty different 10-mer primers were assessed for the RAPD analysis of 16 prey-independent bdellovibrio strains. Four of these primers were used routinely based on their ability to produce consistent banding patterns. Amplification of bdellovibrio genomic DNA using random primers resulted in unique banding patterns for each strain. Figures 1 and 2 illustrate representative gels using OPA2 and OPA3 as random primers.

DISCUSSION

Random amplified polymorphic DNA analysis can be used as an easy and reliable method for assessing genetic similarities and differences between different strains of *Bdellovibrio bacteriovorus*. It was demonstrated that reproducible amplification products could be obtained with primers OPA2, OPA3, OPA4, and OPA5. The RAPD products generated were dependent upon the primer and strain used. Different primers resulted in

BEST COPY AVAILABLE

different banding patterns Combining the data generated from each primer, and using those data to generate a dendrogram resulted in seven major groups represented by these strains The relatedness of individual strains to one another is similar to that found by others using different techniques For example, Diedrich, et al showed that strains 100, 114, 109D, 109, 109J were very closely related and distant from strains W, A3 12, and UKi2 which were distantly related to one another Analysis of base composition (% GC) by Seidler, et al showed strains A3 12 and W were very different from all other strains tested Schelling and Conti (1983) showed, using serotyping, that strains 100, Xty, Sa109, 109, 109D, and 109J represented a single serogroup Whereas strains W, UKi1, A3 12, UKi2, SaD3, E, and 2484 were antigenically distinct from other members tested The patterns of relatedness as determined by RAPD analysis are consistent with these previous results and are extended to include additional strains RAPD analysis has therefore been shown to be a simple and effective method to differentiate bdellovibrio strains

Biogerontology research has shown that longevity is a polygenic character. The objective of this study was to identify small chromosomal regions that are associated with long life span in *Drosophila melanogaster*. Using the quantitative trait loci (QTL) mapping technique, the *D. melanogaster* genome was screened for genetic markers associated with extended longevity. Long-lived lines were screened for polymorphic markers distinct from two control lines. The screening procedure involved 150 oligonucleotide primers of arbitrary sequence in the polymerase chain reaction (PCR). Twenty-three primers consistently produced a band that appeared in the long-lived lines and was absent in the controls or vice versa. A backcross population was created to test whether these markers would segregate with the long-lived trait. Only one of these primers, N14, gave a marker that was associated with longevity. The distinguishing band was extracted from the gel, purified, and sequenced. The resulting 709 base pair DNA fragment was used in biotinylated DNA in situ hybridization by Dr. Tatar. This fragment hybridized to band 64B on the left arm of the third chromosome. Sequence homology was searched for against current DNA and protein databases with no significant matches found. Computer analysis suggests that this DNA fragment is non-coding, but is located near a gene or genes influencing longevity. In conclusion, a small chromosomal region has been found that seems to be strongly associated with long life, and experiments are in progress to search for other genetic markers in this area.

INTRODUCTION

Life span is determined by various environmental, epigenetic, and genetic components. Environmental factors such as high larval density in *Drosophila melanogaster* have been shown to increase longevity (Khazaeli et al., 1997). Low temperatures and dietary restriction also increase life span in vertebrate organisms. Regulation of gene expression can also contribute directly to life span changes in *D. melanogaster*. Rogina and Helfand (1995) found that the expression of a gene was altered in direct proportion to the animal's life expectancy. In addition to environmental and epigenetic factors, the genotype of an organism plays a major role in determining longevity (Curtsinger et al., 1995). Identifying individual genes that increase longevity in organisms is a task within reach. Single genes involved in longevity have been found in the worm *Caenorhabditis elegans* (Friedman and Johnson, 1988).

Genetic changes affecting the physiological or metabolic mechanisms of organisms can alter their longevity. Changes in genes involved in maintenance and repair of the organism may increase life span by maintaining the optimal functioning of the genetic machinery of an organism. Genes involved in determining an organism's metabolic capacity and stress responses are thought to be key players in determining longevity. The metabolic capacity of long-lived flies is increased at any temperature (Arking et al., 1988). Therefore, genes that increase metabolic capacity in an organism may increase its life span. Selection for stress resistance in *Drosophila* has been shown to increase longevity; therefore, alleles that increase stress resistance may also increase longevity (Rose et al., 1992).

Further evidence of the importance of genes involved in the determination of longevity is exemplified by the selection of *Drosophila* for extended longevity. The genetic variance within a population allows for selection of individuals exhibiting certain phenotypes. If these traits are heritable, they will be passed on to the next generation at a high frequency and eventually a population will emerge with a genotype favoring a selected phenotype. Initial selection for late reproduction over 13 generations resulted in two lines of *D. melanogaster* with a mean longevity 27% greater than the control lines (Luckinbill et al., 1984). These lines have been maintained in our lab since that time, and the mean longevity of the selected lines is now 40% higher than the control lines (Fukui et al., 1995).

Because *D. melanogaster* can be selected for extended longevity, the frequency of the genetic factors favoring longevity would increase in the long-lived lines. We set out to identify these genetic factors using a polymorphism assay. Products defining the polymorphism exhibit Mendelian inheritance and can be used as genetic markers (Ellsworth et al., 1993). RAPDs (randomly amplified polymorphic DNA) are markers detected by amplifying random DNA segments using PCR and oligonucleotide primers of arbitrary sequence. QTL (quantitative trait loci) are genes that influence a quantitative trait. In our case, the extended longevity phenotype is the characteristic we are trying to localize. QTL analyses using RAPDs can be used to identify linkage between polymorphic markers and a particular trait. This study seeks to find regions in the *D. melanogaster* genome associated with longevity.

MATERIALS AND METHODS

Successful selection for over 50 generations of *D. melanogaster* with extended longevity has been accomplished using selection for late reproduction (stocks supplied by Dr. Leo Luckinbill of Wayne State University). These stocks include two independently maintained outbred control lines (LD_1 and LD_2) and two independently maintained outbred long-lived fly lines (LA and LB) derived from the wild-type controls. The long-lived lines live 40% longer than the control lines (the mean longevity of long-lived lines is 70 days, and the mean longevity of the control lines is 50 days).

DNA was extracted for use in PCR using the Engles' method (Engles et al., 1990). Single flies were macerated in a 0.5 ml tube for 10 seconds with a pipette tip containing 100 µl squishing buffer. The squishing buffer contained 10 mM Tris-Cl [pH 8.2], 1 mM EDTA, 25 mM NaCl, and 200 µg/ml Proteinase K. The tubes were incubated at 37°C for 24 hours. The Proteinase K was inactivated by heating the tubes to 95°C for 2 minutes. The extracts were then centrifuged for 2 minutes and diluted with 100 µl autoclaved nanopure water. The DNA preparation was stored at 4°C.

One hundred and fifty arbitrary oligonucleotide primers were screened for markers distinct for longevity in the four lines. One fly per line underwent initial screening. PCR amplification was carried out in a total of 25 µl with 10 mM Tris-HCl [pH 8.3], 50 mM KCl, 5.0 mM $MgCl_2$, 400 µM dNTPs, 0.7 µM primer, 20 units of AmpliTaq DNA Polymerase-Stoffel Fragment, and 10 ng of DNA template. Prior to amplification, 28 µl Nujol mineral oil was overlaid on each reaction mixture to prevent evaporation. DNA amplification suggested by Burt et al. (1994) was performed with modification for a Hybaid Omnigene Thermal Cycler. After 2 minutes at 94°C, the reaction mix was subjected to 40 cycles of 94°C/ 36°C/ 72°C for 0.5 min./ 0.5 min./ 2 min. The amplification cycles were followed by a 30 minute final extension at 35°C. The products were resolved by electrophoresis for 3 hours at 100 Volts in gels composed of 1.4% agarose in 1X TAE buffer (0.04 M Tris-acetate and 0.001M EDTA). DNA fragments were visualized and photographed under UV light after staining with Ethidium Bromide.

If a band was present in the two long-lived lines and absent in the two control lines (or vice versa) during the initial screening procedure, additional screening followed using 10 flies per line to verify that the trait the band represents was fixed in the long-lived (or control) lines. If the primer consistently showed a distinguishing band in either the long-lived or control lines, it was analyzed further to determine if the desired QTL would segregate with the marker associated with it.

The long-lived flies (LA males, geneotype +/+) were crossed with control lines (LD_1 female virgins -/-). Virgin F3 generation females (+/+; +/-; -/-) from the previous cross were backcrossed with LD_1 males (-/-) to create the backcross fly population (+/-; -/-). The crosses were done by Dr. Hank Fukui. These crosses will maximize the amount of recombination at the site of the marker. The backcross fly population was grown up in two separate cohorts in a cage at 24°C and collected and saved as they died using the methods of Fukui et al. (1993).

The backcross flies underwent PCR analysis using the primers giving distinct banding patterns in the screening procedure. Each fly from the backcross population was tested. Its date of death and presence or absence of the marker was noted. A survivorship curve was created with the data from the backcross male and female progeny. If the backcross flies with the marker showed a significant positive shift in survivorship from the flies without the marker, the band was extracted from the gel and purified using the technique from Li and Ownby (1993). The DNA fragment was then amplified and sequenced using an automated gene sequencer at the Advanced Genetic Analysis Center at the University of Minnesota. The resulting DNA fragment was used in biotinylated DNA in situ hybridization with *D. melanogaster* polytene chromosomes from the LA line by Dr. Marc Tatar (Ashburner, 1989).

Computer analysis of this fragment's sequence was completed using the Advanced Biosciences Computing Center at the University of Minnesota. DNA and protein sequence homology was searched for against the fragment's sequence. Probable protein coding sequences within the fragment were searched for.

RESULTS

Of the 150 primers screened, 23 passed the initial and additional screening procedures by producing a band in either the long-lived or the control lines. The backcross was performed and flies were collected and tested for the markers as they died. A survivorship curve for both males and females was constructed from these data.

Only one primer, N14, had a distinguishing band (Figure 1) and showed a significant shift in the survivorship curve in the flies with the marker. The individuals with the N14 marker in the male survivorship curve for two cohorts had a mean longevity 30% greater than the flies lacking the marker (Figure 2). The curve from flies with the marker in the female survivorship curve did not deviate significantly from the curve from flies without the marker in two cohorts. The distinguishing band was isolated from the gel and sequenced. The DNA fragment was subject to in situ hybridization and found to be on band 64B of the left arm of the third chromosome.

This fragment's sequence underwent computer analyzation for sequence homology and protein coding probabability. No nucleotide sequences were found with a significant match to the sequence. Protein databases were also searched for a match to the DNA fragment, but no significant match was found. Two programs were used to identify possible protein coding regions of the DNA sequence. A stretch of 130 nucleotides in the second reading frame was placed into the uncertainty region for coding for a protein. Most likely this 709 base pair DNA fragment is non-coding.

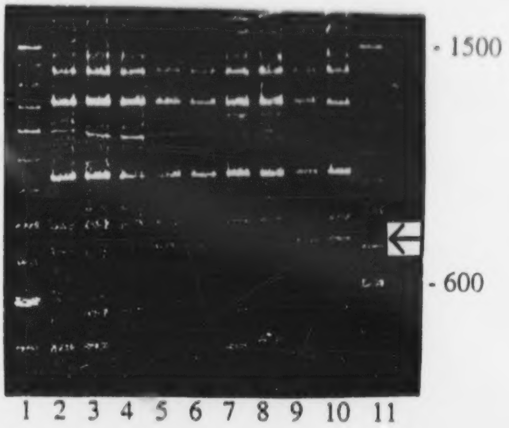

Figure 1. PCR-RAPD results of N14 10-mer
The N14 primer consistently produced a band at 709 bp (arrow) in the long-lived fly lines (LA and LB), and the band was absent in the control lines (LD_1 and LD_2). Lanes 1 and 11: 100 bp DNA ladder; Lane 2: LA female; Lane 3: LD_2 female; Lane 4: LD_2 male; Lane 5: LB female; Lane 6: LB male; Lane 7: LD_1 female; Lane 8: LD_1 male; Lane 9: LA female; Lane 10: LA male. Size marker at right is in base pairs.

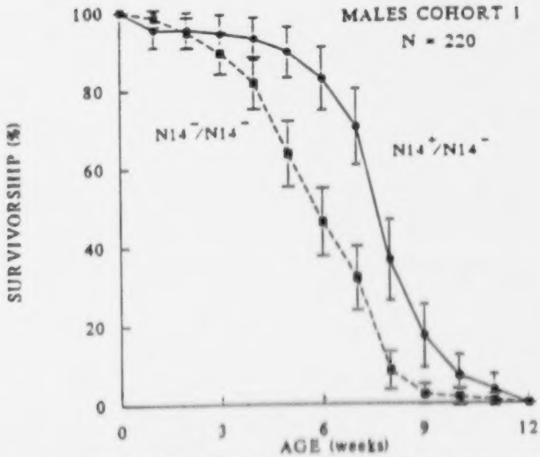

Figure 2. Male survivorship curve for the first of two replicate cohorts from the backcross fly population.
The backcross male flies with the N14 marker (genotype $N14^+/N14^-$) have a significant increase in life span compared to flies without the marker (genotype $N14^-/N14^-$).

CONCLUSION

Our results indicate that we have found a genetic marker associated with the extended longevity phenotype exhibited by the long-lived strain of flies. The similar survivorship curves for both of the male backcross cohorts indicate that this marker is closely linked with a gene influencing longevity in males. Computer analysis suggests the N14 fragment is non-coding and probably lies near a QTL affecting longevity.

There is strong evidence that the QTL associated with the marker was fixed by selection for longevity and not by chance. The long-lived lines were selected for longevity independent of one another. Because both long-lived strains have the N14 marker, the two lines fixed this region of the genome independently. Assuming the frequency of the allele marked by N14 in the population is 0.5 and that the allele is neutral, the probability of the allele fixing in the two long-lived lines and being lost from the two control lines is 0.06. Therefore, the allele associated with the N14 marker did not fix by chance and is useful as a marker. If our marker is indeed detecting a life span associated gene, the two long-lived lines used this same genetic mechanism to extend longevity. The data from the backcross males is further evidence that the region N14 marks is influencing longevity in the flies and is due to selection.

Sex differences exist in this QTL's influence and expression. The survivorship curve from the backcross flies demonstrates that the males with the N14 marker increase their probability of survival at all chronological ages. The survivorship curves for the female backcross flies does not show an association between extended longevity and presence of the N14 marker. A possible reason for this sex difference is that life span extension may utilize different mechanisms in males and females. Luckinbill et al. (1988) found that the genes determining longevity in *D. melanogaster* appear to differ between males and females in a chromosomal substitution study. This study found evidence for differences in the influence of certain genetic elements influencing longevity between males and females, and also, the genetic controls for longevity themselves differed between the sexes in some instances. This phenomenon has also been observed in the expression of bristle number in *D. melanogaster* (Mackay et al., 1992). In this study, they found chromosomal regions strongly associated with bristle number in females were not the same chromosomal regions utilized by males.

Localization of the N14 fragment to the third chromosome is consistent with other studies involving the genes participating in longevity. Buck et al. (1993) found that mean longevity is influenced primarily by the third chromosome. Luckinbill et al. (1988) also found that the third chromosome was the most powerful contributor in the control of longevity using a chromosomal substitution experiment.

The 23 primers that did not show significant effects in the survivorship curves with the backcross population may still influence longevity, but may only have a small effect. This effect may have been lost more easily through recombination because of its small role. Another interpretation to consider is that the marker may have been too far away from the gene influencing longevity, and the marker may have been lost by recombination events. These primers may also amplify regions of the genome which had fixed by chance in either the selected or control lines.

The next step is to identify, characterize, and isolate other markers involved in the expression of extended longevity in our invertebrate model organism. When more QTL markers have been defined and studied, analogous aging processes can be searched for that may occur in vertebrates if the genes exhibit evolutionary conservation. Further studies to unravel life span determining processes could link our marker to its specific function. Also, the sequencing of the *Drosophila* genome and subsequent elucidation of DNA function may lead to understanding the genetic significance of the N14 fragment.

ACKNOWLEDGEMENTS

I would like to thank Professor Jim Curtsinger for the financial and academic support of my Honors project. I would also like to thank Dr. Henry Fukui, Dr. Aziz A. Khazaeli and Dr. Marc Tatar for their technical assistance, Scott Pletcher for his computer expertise and review of this paper, and Kristi Kelly and Andrew Kirscher for their support.

BACKGROUND

The 26 April 1986 meltdown of reactor 4 at the Chernobyl Nuclear Power Plant is the world's worst nuclear power plant disaster. Over 50 million Curies were released into the environment, and the regions surrounding the reactor remain highly polluted both with radioactivity and other meltdown related contaminants (Mourad and Snell, 1987; Powers et al., 1987). The Ukrainian government maintains two exclusion zones surrounding the reactor with radii of 10 and 30 km. The 10 km zone includes the most radioactive regions, and human activity is kept to a minimum). The abundance and diversity of small mammals within the exclusion zones is equal to or greater than that of similar areas outside the contaminated regions (Baker et al. 1996). The abundance of small mammals within the exclusion zones is probably largely attributable to the absence of human activity in those areas.

Two species of voles, *Microtus arvalis* and *M. rossiaemeridionalis*, are among the most common rodents living in both the experimental and control regions. Data from *Microtus* suggest that at least some individuals living in the zone would receive doses ranging from 370 to 960 Rads in a six month period. (Chesser et al., submitted manuscript). Although numerous studies have shown that acute exposure to high radiation doses induces chromosomal breaks and rearrangements, no significant difference in the frequency of chromosomal breaks between experimental and control populations has been observed in any of the small mammal species examined from the Chernobyl region (Baker et al., 1996). A reciprocal translocation in a single individual of *Microtus oeconomus* collected from the Chernobyl area has been reported (Nadzhafova et al., 1994), but as only single individuals from both the contaminated and control regions were examined, the evidence to attribute the presence of the rearrangement to the radioactive environment at Chernobyl is limited. The *M. oeconomus* study utilized differential staining of chromosomes to reveal a small structural change in a single individual, whereas the Baker et al. (1996) study focusing on gross karyotypic changes did not reveal significant increases in the frequency of rearrangements. Because the chronic radiation doses (lifetime total of internal and external) received by voles at Chernobyl are comparable in magnitude to the acute radiation doses which have been shown to induce significantly increased frequencies of chromosomal breaks and rearrangements in *Microtus* (Cooper and Hsu, 1971), we have tested for the presence of more subtle chromosomal effects that might not be revealed by analysis of gross karyotypic morphology.

Heterochromatin has been shown to be a dynamic genomic element which may undergo significant changes between closely related taxa as well as among individuals in a single population (Hamilton et al., 1990). Therefore, we have analyzed the stability of heterochromatin in voles from the most radioactive regions at Chernobyl. If the radioactive environment is having an effect on the chromosomal structure and organization in voles from Chernobyl, we would expect to see differences in amounts and positional arrangement of heterochromatin between the experimental and control populations. If the radioactive environment is not affecting the chromosomal architecture in voles (the null hypothesis) we would expect to see no significant differences in heterochromatin position and arrangement between the zone and control populations.

The experimental design was to isolate DNA fragments that in the representative karyotypes of both *Microtus arvalis* and *M. rossiaemeridionalis* correspond to heterochromatic regions. Fragments were preferentially chosen that were either unique to one of the two species or that showed the greatest differences in copy number between the two species. We assumed that DNA fragments showing the greatest differences between these two closely related species of *Microtus* would be more dynamic than those conserved between these species, and thus more likely to reveal any recent environmentally induced changes.

MATERIALS AND METHODS

Library Construction

Plasmid libraries were constructed from genomic DNA isolated from a male specimen collected from the native vole populations in the most radioactive regions at Chernobyl (*Microtus arvalis*, TK 44564; *M. rossiaemeridionalis* TK 44575) (see Baker et al., 1996 for collection details). Genomic DNA was partially digested with *Sau*3AI and visualized on an agarose gel stained with ethidium bromide. The size fragments ranging from 6-8 kb were removed from the gel and isolated by electroelution following the procedures of Sambrook et al. (1989). DNA fragments were ligated into Bluescript (BSSK-) cut with *BamH*I and dephosphorylated with calf alkaline intestinal phosphatase following the manufacturer's instructions (New England Biolabs) and transformations were accomplished using electroporation with ElectroMax competent cells (DH10B) (Gibco BRL) following the manufacturer's instructions. Colonies were selected by color using X-gal and IPTG as described in Sambrook et al. (1989). Colonies (1920 for *M. arvalis*, 960 for *M. rossiaemeridionalis*) were picked and archived

BEST COPY AVAILABLE

into 96-well microtiter plates.

Library Screening and Isolation of Clones
Membranes were inoculated with all archived clones from each library and hybridized with the genomic DNA of both species of *Microtus* following the procedures of Van Den Bussche et al. (1995). Clones which showed either hybridization with genomic DNA of only one species or which showed the greatest differences in signal intensity between the two species were used as probes for fluorescent in situ hybridization.

Karyotypic Procedures
Individuals were collected from natural populations and karyotypes were derived from bone marrow preparations as described in Baker et al. (1996).

Fluorescent in situ hybridization
Probes for fluorescent in situ hybridization were labeled by standard nick-translation with biotinylated dUTP using the Clontech Biotin-21-dUTP nick translation kit following the manufacturer's instructions. Hybridization followed the procedures of Hamilton et al. (1990). At least 10 complete spreads per individual were analyzed using an Olympus Epi-fluorescent microscope.

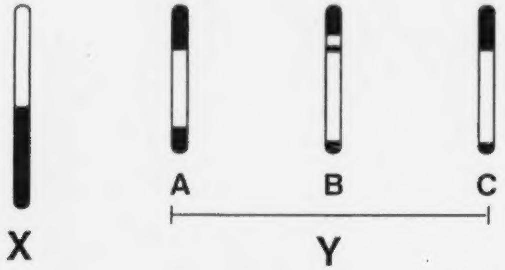

Figure 1--Diagrammatic representation of the sex chromosomes of *M. rossiaemeridionalis* hybridized with the clone pMr1TT. Hybridization is indicated by black.

RESULTS

One variable clone was isolated from *M. rossiaemeridionalis*. This clone, designated pMr1TT is specific to the sex chromosomes of *M. rossiaemeridionalis*. The hybridization occurs as a large block on the X chromosome and with blocks arranged in one of three patterns on the Y chromosome (Fig. 1). The relative proportions of these three patterns are shown in Table 1.

Clone pMr2TT is another sex associated *M. rossiaemeridionalis* fragment which hybridizes to the centromeres of every chromosome of *M. rossiaemeridionalis* except the Y. No variance in this pattern of hybridization has been observed (12 individuals examined: 9 experimental, 3 control).

Clone pMa1TT hybridizes to the centromeres of eighteen small chromosomes of *M. arvalis*. No variation in the hybridization pattern of this probe has been observed (8 individuals examined: 6 experimental, 2 control).

CONCLUSION

Intra-populational variation in heterochromatin arrangement was observed with the DNA fragment designated as pMr1TT. However the distribution of the three patterns of heterochromatin on the Y chromosome does not differ significantly different between the experimental and control populations Table 1). Therefore, this variation is most likely a natural polymorphism.

With the analysis of three different DNA fragments corresponding to heterochromatic regions in *Microtus arvalis* and *M. rossiaemeridionalis*, no differences in pattern of heterochromatin arrangement have been observed between the experimental and control populations. It is unclear why this data set failed to reveal chromosomal breaks and rearrangements as had been reported previously in *Microtus* exposed to significant radiation doses (Cooper and Hsu, 1971; Nadzhafova et al., 1994). Perhaps in the Chernobyl vole populations differences in the arrangement of heterochromatin do exist which have not been revealed with the heterochromatic sequences used in this analysis. The absence of detectable chromosomal rearrangements in voles from the Chernobyl region could be due to sampling error. Another possible explanation is that the voles currently living near the Chernobyl reactor have undergone selection for more efficient repair mechanisms than would be present in naive mice without a genetic background of more than ten years of chronic exposure to high levels of radiation.

This data along with the absence of gross karyotypic changes suggest that the long term chromosomal effects of the Chernobyl disaster are not as great as might have been predicted by previous laboratory studies. If long term chromosomal effects are present, more sensitive methods will be required to interrogate them.

ACKNOWLEDGMENTS

Drs. Ron Van Den Bussche and Meredith Hamilton provided both technical expertise and assistance in experimental design. This research is the result of a larger project at Chernobyl initiated by Dr. Ronald Chesser. Support for this research was provided [in part] by a grant from the Howard Hughes Medical Institute through the Biological Sciences Undergraduate Education Program at Texas Tech University.

ABSTRACT

CXCR4 has recently been identified as one of the chemokine receptors that function as a coreceptor for HIV entry into CD4+ human cells. The goal of these experiments is to study the interaction of CXCR4 with HIV-1 envelopes. We have isolated the CXCR4 genes from the chimpanzee, rhesus macaque, and the African green monkey. We compared the ability of human, rat, and these newly isolated non-human primate CXCR4s to mediate HIV-1 infection. Only the human and non-human primate CXCR4s mediated the entry of a vector expressing the V1-V3 domains of an SI strain of HIV-1. The predicted amino acid sequence comparison among human, rhesus, and rat CXCR4s showed a small amount of variation in the transmembrane and intracellular domains. The extracellular domains of the rat showed significant variation with respect to the primate sequences.

INTRODUCTION

Human Immunodeficiency Virus (HIV) is the etiological agent of Acquired Immunodeficieny Syndrome (AIDS). HIV-1 infects T lymphocytes, monocytes, dendrytic cells, and microglia (Gartner et.al. 1986, Koenig et.al. 1986, Pope et.al 1994, Weisman et.al 1995). The initial step in the HIV lifecycle is entry into the host cell, which requires binding of the viral envelope glycoprotein, gp120, to the amino terminal domain of CD4 (McDougal et.al. 1986, Helseth et.al 1990). The cell surface expression of CD4 is therefore required for HIV-1 entry (McDougal et.al. 1986, Maddon et.al. 1986), but is not sufficient for fusion of the viral envelope and the host plasma membrane (Maddon et.al. 1988, Hoxie et.al 1988, Clapham et.al 1992, Dragic et.al. 1995). The fusion reaction requires additional host cell factors, which determine the specificity exhibited by HIV-1 variants in fusing with particular subsets of CD4 positive cells (Ashorn et.al. 1990). Two groups of HIV isolates an be identified based on their tropism. The majority of virus isolates present in the beginning of an infection are macrophage-tropic, nonsyncytium-inducing (Zhu et.al. 1993). These strains appear to be responsible for sexual transmission, and predominate during the asymptomatic phase of infection. T-tropic, syncytium inducing strains appear later in the course of the infection in 50% of AIDS patients, often preceding the onset of AIDS symptoms (Termette et.al. 1989).

HIV-1 tropism is largely determined by differences in the third variable region of the viral envelope glycoprotein (Cheng-Mayer et.al. 1990, O'Brien et.al. 1990, Hwang et.al 1991, Westervelt et.al 1991, 1992, Chesebro et.al 1992, Willey et.al 1994). Extensive homology has been found among the sequences of the V3 hypervariable region of macrophage-tropic isolates. In contrast, the V3 sequences of T cell-tropic strains show heterogeneity. Because the sequence variability among clones derived from individual patients was found to be low compared to the variability among different patients, it can be concluded that sequence diversity must arise independently in each individual (Chesebro et.al 1992). Amino acid substitution experiments indicate that V3-induced changes in viral tropism are accompanied by physical and functional modifications of the viral envelope (Willey et.al 1994).

As a result of differences in the V3 domain of the envelope glycoprotein, the two subsets of HIV-1 isolates utilize two different molecules for cell fusion and entry (Cocchi et.al. 1996). The cell fusion and entry of macrophage-tropic strains is mediated by CCR5 (Alkhatib et.al. 1996, Choe et.al. 1996, Deng et. al. 1996, Doranz et. al. 1996, Dragic et. al. 1996, Feng et.al. 1996), while cell fusion and entry of T-tropic strains is mediated by CXCR4 (Feng et.al. 1996). Both CXCR4 and CCR5 are chemokine receptors, which are seven-transmembrane GTP-binding protein coupled molecules, which respond to ligand binding by transducing an intracellular signal that results in the mobilization of intracellular calcium.

Chemokines are a family of proteins that play a role in the selective activation and recruitment of a large variety of cell types in inflammation. They are subdivided into two groups based on the spacing of cysteine residues at the N-terminal. CXC chemokines have an intervening amino acid separating their first and second cysteine residues, while in CC chemokines these first two residues are adjacent. Most CXC chemokines activate neutrophils but not monocytes. In contrast, CC chemokines show reciprocal activity, and activate monocytes, lymphocytes, basophils, and eosinophils but not neutrophils (Baggiolini et.al 1994, Schall and Bacon 1994).

Here we compare the function of human CXCR4 receptor with various non-human primate and rat CXCR4-R's. By comparing the sequences of these clones and their ability to mediate HIV infection we hope to identify the parts of the CXCR4 receptor that are involved in the interaction with the HIV-1 envelope glycoprotein during the fusion reaction.

MATERIALS AND METHODS

Cell lines: COS-CD4 cells (Camerini, Planelles, Chen 1994), HeLa-CD4 cells (Camerini, Seed 1990), and 293T cells obtained from Dr. Judith White (University of Virginia), were grown in Dulbeco's Modified Eagle's medium containing 10% bovine serum.

CXCR4 plasmids: All non-human primate and human CXCR4 genes were cloned by PCR from stimulated T-cell cDNA libraries (Camerini and Seed 1990, Camerini et.al. 1989) into the plasmid CDM8 (Seed 1987) using the Hind-III (5') and Not-1 (3') restriction sites. The rat CXCR4 gene cloned into the vector pCDNA were a kind gift of Dr. Jeff Harrison (University of Florida). The construction of the CD7 expressing vector piH3 has been described in Aruffo and Seed 1987. HIV-Luc construct: The construction of the NL-Luc Env$^-$ Vrp$^-$ HIV-1 luciferase vector was described in Connor et.al. 1994 (Figure 1).

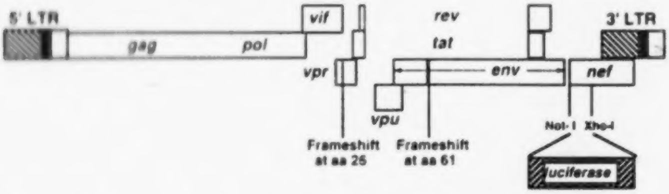

FIGURE 1. Diagram of NL-Luc Env$^-$ Vpr$^-$, a defective HIV-1 Luciferase vector. The vector is based on the infectious molecular clone of HIV-1, NL4-3, but has inactive vpr, env, and nef genes due to frameshift mutations at amino acids 26 and 61, and the insertion of the luciferase gene at the Not-1 and Xho-1 sites of nef.

Envelope vectors: The VSV-G gene cloned into the expression vector piLGPYI is described in Aruffo and Seed (unpublished). The construction of the vector pLET expressing the LAI envelope has been described in Emerman 1989., and was a kind gift of Dr. Francoise Bachelerie, Pasteur Institute. The JR CSF envelope gene (Koyanagi et.al. 1987) and the JR CSF Pt.A V1V3 envelope gene (Camerini et.al. manuscript in preparation) cloned into the vector pCMV were a kind gift of Nathalie Chazal.

Electroporation: 50% confluent 15cm plates of COS-CD4 cells were trypsinized and washed with 10% fetal bovine serum. 30 μg of plasmid DNA was added to 20,000,000 cells in 0.5 ml of 20% fetal bovine serum. After a 10 minute incubation on ice, cells were electroporated with 250V, and after another 10 minute incubation on ice they were plated onto a 10cm plate. 24 hours after electroporation, cells were trypsinized and replated into 6-well plates at a concentration of 200,00 cells/well. 48 hours later, cells from one well were detached by treatment with Phosphate Buffered Saline (PBS) and 0.5mM EDTA. The cell suspension was washed with PBS and resuspended in FACS staining buffer. CXCR4 transfected cells were incubated with anti-CXCR4 monoclonal antibody (Mab), followed by fluorescence conjugated IgG fraction of goat-antimouse MAb (12G5) (Endres et.al. 1996) and anti CD4 Mab (Caltag, San Fransisco, CA). CD7 transfected cells were incubated with CD7 Mab (Caltag, San Fransisco, CA). The levels of CD4 and CXCR4 or CD7 were measured by FACS analysis.

Viral infection assay: Viral stocks were generated by CaPO$_4$ precipitate transfection of subconfluent 15cm plates of 293T cells with 21μg of HIV Env vector DNA and 7 μg of HIV-Luc vector. Supernatants were collected 72 hours post-transfection and were diluted 1:3 with 10% bovine serum. 3 ml aliquots were used to infect 200,000 COS-CD4 cells 3 days post-electroporation. 3 days after infection, cells were lysed, fixed, and luciferase activity was measured according to Analytical Luminescence Laboratory' s Luciferase Assay Kit.

RESULTS

Flow cytometric analysis of transfection efficiencies. COS-CD4 cells transfected with primate CXCR4s showed 25-35% CXCR4 expression. Rat CXCR4 expression could not be measured by this method due to the lack of a reaction with the monoclonal antibody 12G5. Because the plasmid vector expressing the rat CXCR4 gene has the same promoter, enhancer, and SV40 replication origin as the vectors carrying the primate CXCR4s, we expect a similar level of expression. We will measure mRNA levels to verify this assumption. Figure 2 shows a typical result of the flow cytometric analysis.

All of tested primate CXCR4s, but not rat CXCR4 allowed entry of the JR-CSF Pt. A SI V1-V3 Env pseudotyped HIV-1 Luciferase vector into COS-CD4 cells. To investigate whether various CXCR4s were able to function as a coreceptor and mediate viral entry at the COS-CD4 cell plasma membrane, we tested whether they allowed infection by an HIV-Luc vector pseudotyped with different envelopes. We measured the level of infection by measuring luciferase activity 3 days after infection. COS-CD4 cells do not normally express CXCR4. Supernatants from 293T cells cotransfected with NL-Luc E R HIV-1 vector (Figure 1) and a panel of envelope expressing vectors were used to infect COS-CD4 cells. The supernatants contained HIV-1 Luc virions bearing the cotransfected envelope. A VSV-G expressing vector was used as a positive control for infection. VSV-G interacts with phosphatidyl serine, and thus CXCR4 is not required for entry into the cell. A HIV-1 JR-CSF envelope expressing vector was used as a negative control for infection. HIV-1 JR-CSF is a macrophage-tropic, non-syncytium inducing strain of HIV that uses CCR5 as a coreceptor. CXCR4 cannot mediate entry of virions bearing this envelope. An HIV-1 JR-CSF envelope carrying the V1-V3 region of a TLCL-tropic, syncytium inducing, HIV-1 isolate from patient A, was used to test the coreceptor function of the non-human primate and rat CXCR4s. Results of the luciferase assays showed that all non-human primate CXCR4s allowed entry of the JR-CSF Pt.A SI V1-V3 Env pseudotyped HIV-1 luciferase vector into COS-CD4 cells, but did not allow entry of the JR-CSF Env pseudotyped HIV-1 luciferase vector. Rat CXCR4 did not allow the entry of virions bearing either envelope. The VSV-G pseudotyped HIV-1 Env, however, entered both primate and rat CXCR4 transfected cells, showing that all cells were competent to support the other stages of the viral lifecylce necessary for luciferase expression. (Figure 2)

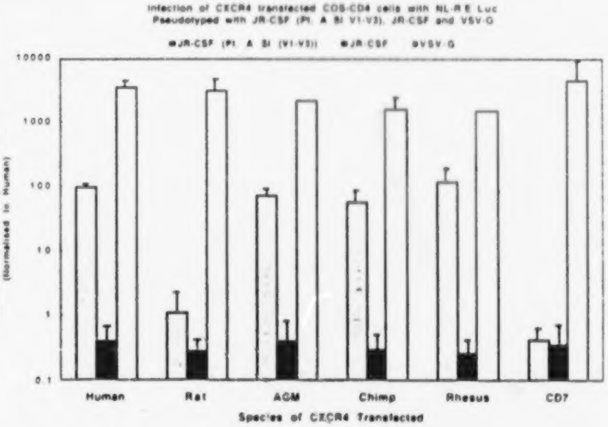

FIGURE 2. Luciferase assay of NL-Luc E R infected COS-CD4 cells. All non-human primate CXCR4s allowed entry of the JR-CSF Pt. A SI V1-V3 Env pseudotyped HIV-1 luciferase vector into COS-CD4 cells, but did not allow the entry of HIV-1 JR-CSF Env pseudotyped HIV-1 luciferase vector. Rat CXCR4 did not allow the entry of virions bearing either envelope. VSV-G pseudotyped HIV-1 Luc entered both primate and rat CXCR4 transfected cells.

Analysis of CXCR4 amino acid sequences. The amino acid sequences of human, rhesus, and rat CXCR4s were obtained from Genbank. Comparison of the three sequences showed a small amount of variation in the transmembrane and intracellular domains of the three species. In contrast, the extracellular domains of the rat sequence showed significant variation from the primate sequences.

FIGURE 3. Predicted amino acid sequence alignment of human, Rhesus macaque, and rat CXCR4s. The amino acid sequences were obtained from Genbank. The seven transmembrane domains are underlined. Consensus among the three sequences is shown on the bottom line.

DISCUSSION

The aim of our study was to isolate and analyze the function of several non-human primate CXCR4 genes. Our results indicated that while all of the non-human primate CXCR4s successfully functioned as a coreceptor, and mediated the entry of JR-CSF Pt. A SI V1-V3 Env pseudotyped HIV-1 luciferase vector into COS-CD4 cells, the rat CXCR4 did not. None of the CXCR4s allowed the entry of the CSF Env pseudotyped HIV-1 luciferase vector, confirming that the V3 domain of this envelope cannot interact with CXCR4 to mediate fusion and entry into cells.

Predicted amino acid sequence analysis of human, rhesus, and rat CXCR4s showed that transmembrane and intracellular domains are conserved among these three species, displaying mostly conservative variation. Extracellular domains of the rat sequence show significant variation with respect to the primate sequences (Table 1). Further experiments will be performed to identify which of these amino acid residues may be involved in interacting with HIV-1 to facilitate viral entry.

TABLE 1. Percentages of amino acid sequence variability. Intracellular and transmembrane domains of human, rhesus, and rat CXCR4s show only a small amount of mostly conservative variation among the three species. Extracellular domains of the rat sequence show significant variation with respect to the primate sequences.

Percentages of Amino Acid Sequence Variability Between Human, Rhesus, and Rat CXCR4s

	Extracellular Domains		Transmembrane Domains		Intracellular Domains	
	%Variation	%Significant Variation	%Variation	%Significant Variation	%Variation	%Significant Variation
Rat to Human	24	12	4	0.7	4.8	0
Rhesus to Human	4	0.9	0.7	0.7	0.9	0
